The horizon is not normally visible on high panoramic imagery. In only one pass over the target area, panoramic photography provides coverage of large areas of terrain on both sides of the aircraft flight path. Although it provides both vertical and oblique views of the image area, it is the most difficult and time-consuming photography to analyze and measure, owing to the distortion of the recorded image. Table A-1 on page A-4

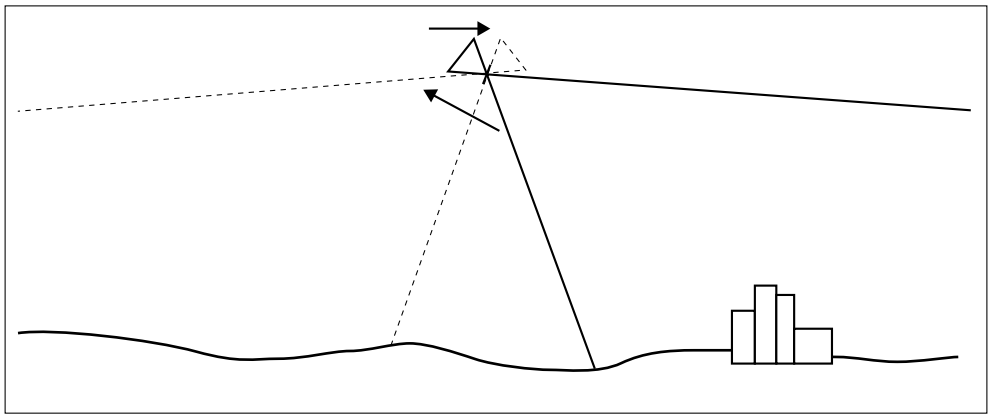

Figure A-4. Low Panoramic Imagery.

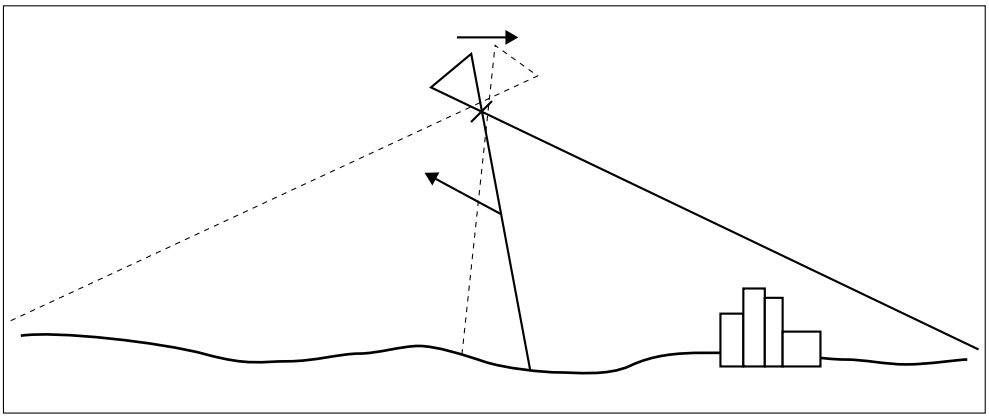

Figure A-5. High Panoramic Imagery.

summarizes both the advantages and disadvantages of each type of imaging system.

Capabilities of optical sensors are—

- High quality photograph (good resolution).
- Passive system, which cannot be detected or jammed.
- Flexibility of sensors.

Limitations of optical sensors are—

- Light source needed.
- Hampered during periods of reduced visibility.
- Susceptible to enemy deception.
- LOS dependent.

High Resolution Radar

Radar is an active sensing technique that detects and records differences in reflected electromagnetic energy.

Capabilities of high resolution radar are—

- Offers day and night operations.
- All-weather capability.
- Standoff capability.

Table A-1. Advantages and Disadvantages of Imaging Systems.

Sensor System	Advantages	Disadvantages
Vertical	Fairly constant scale. Can construct mosaics. Obtains accurate measurements. Allows stereographic viewing. Accurate interpretation.	Aircraft or air vehicles must fly directly over the target. Objects under overhead cover cannot be viewed. Unnatural view angle. Some areas are inaccessible due to restrictions in over-flights (tactical systems).
Oblique	Large area coverage. More natural view. Aircraft or air vehicle does not fly over the target. Can view objects under cover due to angle.	Terrain masking. Scale varies. Measurements difficult.
Panoramic	Large area coverage. Satisfies both vertical and oblique mission requirements.	Scale varies. Aircraft has limited standoff capability. Measurements difficult.

Limitations of high resolution radar are—

- Poor resolution.
- Active sensing techniques.
- LOS dependent.

Infrared

Infrared (IR) sensors detect and record electromagnetic radiation that is emitted from a given target surface in the IR portion of the electromagnetic spectrum.

Capabilities of IR are—

- Offers day and night operations.
- Has passive sensing techniques.
- Detects camouflage equipment and activity.

Limitations of IR are—

- Poor resolution.
- Susceptible to enemy deception.
- Hampered by rain, snow, hail, etc.
- LOS dependent.

APPENDIX B. NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

Background

Imagery analysts use the National Imagery Interpretability Rating Scale (NIIRS) to define and measure the quality of images and performance of imaging systems. Through a process referred to as rating an image, the NIIRS is used by imagery analysts to assign a number indicating the interpretability of a given image. The NIIRS concept provides a means to directly relate the quality of an image to the interpretation tasks for use. Although the NIIRS has been primarily applied in the evaluation of aerial imagery, it also provides a systematic approach to measuring the quality of photographic or digital imagery, the performance of image capture devices, and the effects of image processing algorithms.

The NIIRS is a task-based scale consisting of nine graduated levels. At each level, representative exploitation tasks (termed criteria) indicate the level of information extracted with an image of a given interpretability level. For example, with a NIIRS 2 image, imagery analysts should be able to detect large hangars at an airfield, while with a NIIRS 8 image; they should be able to identify the rivet lines on bomber aircraft. At a higher NIIRS level, more detailed information can be obtained from an image.

The NIIRS is designed to relate to a wide range of image quality. A NIIRS level of 0 is defined as having no value for intelligence purposes. The definition of that level is open to debate. The upper end of the scale is defined by the best available imagery of a given type; i.e., a portion of the spectrum. The upper end of a scale is not necessarily indicative of any specific operational system.

The NIIRS measures the information potential; i.e., interpretability of an image. This means that specific objects listed in the criteria need not be present, but the physical attributes of the image are such that the image would have the specified information value if the necessary content were present. The NIIRS relies on the experience of imagery analysts to be able to extrapolate, or imagine, how well criteria would be rendered if those features were present in the image to be rated. Because each rating refers to specific tasks the imagery analyst can or could do, it has a more precise meaning than, for example, when such subjective words as good or fair are used. Thus, judgments become more uniform, because imagery analysts can use the same yardstick to measure interpretability.

The NIIRS accounts for the major factors that affect image interpretability. Image resolution, measured as ground resolved distance or ground sample distance, has a significant effect on interpretability. Spatial resolution alone does not determine the NIIRS of an image, since sharpness, noise, and contrast also influence the NIIRS. These effects may be due to system parameters (e.g., optical quality, focal plane characteristics), acquisition conditions (e.g., sun angle, atmospheric haze), and exploitation conditions (e.g., duplicate film quality, softcopy monitor quality). By design, the NIIRS is independent of a particular imaging system. NIIRS ratings and ranges are—

NIIRS Rating	Range in Meters
0	N/A
1	over 9.0
2	4.5–9.0
3	2.5–4.5
4	1.2–2.5
5	0.75–1.2
6	0.40–0.75
7	0.20–0.40
8	0.10–0.20
9	less than 0.10

Principal Uses of NIIRS

There are several primary uses for the NIIRS. These are—

- Communicating imagery interpretability. (Can this image answer the IR, both now and archived?
- Developing collection requirements. (Can an imagery system collect the required information? Can the currently available imagery missions collect the information?)
- Assessing mission collection satisfaction. (Does the image satisfy the intelligence requirement?)
- Assessing technical performance. (Is the imagery system working as planned?)

Procedure for Assigning NIIRS Rating Levels Criteria

The NIIRS criteria are expressed in terms of detect, identify or distinguish between objects, features or activities.

Detect is the capability to find or discover the presence or existence of an installation, object, activity or item of intelligence interest based on its general shape (configuration) and on other contextual information in the scene. Some level of identification is implied in detection, so that the relatively gross feature or item detected can be properly named or classified.

Identify is the capability to name an object by type or class based primarily on its configuration and detailed components. As used in NIIRS, identification is based on observation of actual physical detail and not through information from other sources.

Distinguish between is the capability to determine that two detected objects are of different types or classes based on one or more distinguishing features.

Guidelines

The following guidelines allow NIIRS to be used to communicate image interpretability, to evaluate mission performance, and to plan for new imagery systems.

- When assigning a NIIRS level, the imagery analyst evaluates a target within an imagery segment or the entire area on the segment, as necessary, to meet the imagery analyst's task. The imagery analyst will assign a NIIRS level that best characterizes the overall interpretability of the target or area.
- The imagery analyst should neither ignore nor emphasize exceptionally good or poor portions of the image segment.
- When considering clouds, shadows or other localized degradations, the imagery analyst rates the target or area with NIIRS level 0 only when the degradation precludes using it for interpretation. If the area of interest is degraded but interpretable, the imagery analyst should assign a NIIRS that best represents its interpretability.
- The imagery analyst should ignore shadows cast by individual items of intelligence interest.

SECTION I. VISIBLE NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

NIIRS Rating	Description
0	Interpretability of the imagery is precluded by obscuration, degradation or very poor resolution.
1	Detect a medium-sized port facility and/or distinguish between taxiways and runways at a large airfield.
2	Detect large hangars at airfields. Detect large static radars (e.g., AN/FPS-85, COBRA DANE, PECHORA, HENHOUSE). Detect military training areas. Identify an SA-5 site based on road pattern and overall site configuration. Detect large buildings at a naval facility (e.g., warehouses, construction hall). Detect large buildings (e.g., hospitals, factories).
3	Identify the wing configuration (e.g., straight, swept delta) of all large aircraft (e.g., 707, CONCORD, BEAR, BLACKJACK). Identify radar and guidance areas at a SAM site by the configuration, mounds, and presence of concrete aprons. Detect a helipad by the configuration and markings. Detect the presence/absence of support vehicles at a mobile missile base. Identify a large surface ship in port by type (e.g., cruiser, auxiliary ship, noncombatant/merchant). Detect trains or strings of standard rolling stock on railroad tracks (not individual cars).
4	Identify all large fighters by type (e.g., FENCER, FOXBAT, F-15, F-14). Detect the presence of large individual radar antennas (e.g., TALL KING). Identify, by general type, tracked vehicles, field artillery, large river-crossing equipment, wheeled vehicles when in groups. Detect an open missile silo door. Determine the shape of the bow (pointed or blunt/rounded) on a medium-sized submarine (e.g., ROMEO, HAN, Type 209, CHARLIE II, ECHO II, VICTOR II/III). Identify individual tracks, rail pairs, control towers, and switching points in rail yards.
5	Distinguish between a MIDAS and a CANDID by the presence of refueling equipment (e.g., pedestal and wing pod). Identify radar as vehicle-mounted or trailer-mounted. Identify, by type, deployed tactical SSM systems (e.g., FROG, SS-21, SCUD). Distinguish between SS-25 mobile missile TEL and missile support vans in a known support base, when not covered by camouflage. Identify TOP STEER or TOP SAIL air surveillance radar on KIROV-, SOVREMENNY-, KIEV-, SLAVA-, MOSKVA-, KARA-, or KRESTA-II-class vessels. Identify individual rail cars by type (e.g., gondola, flat, box) and/or locomotives by type (e.g., steam, diesel).
6	Distinguish between models of small/medium helicopters (e.g., HELIX A from HELIX B from HELIX C, HIND D from HIND E, HAZE A from HAZE B from HAZE C). Identify the shape of antennas on EW/GCI/ACQ radars as parabolic, parabolic with clipped corners or rectangular. Identify the spare tire on a medium-sized truck. Distinguish between SA-6, SA-11, and SA-17 missile airframes. Identify individual launcher covers (8) of vertically launched SA-N-6 on SLAVA-class vessels. Identify automobiles as sedans or station wagons.
7	Identify fitments and fairings on a fighter-sized aircraft (e.g., FULCRUM, FOXHOUND). Identify ports, ladders, and vents on electronics vans. Detect the mount for antitank guided missiles (e.g., SAGGER on BMP-1). Detect details of the silo door hinging mechanism on Type III-F, III-G, and II-H launch silos and Type III-X launch control silos. Identify the individual tubes of the RBU on KIROV-, KARA-, and KRIVAK-class vessels. Identify individual rail ties.
8	Identify the rivet lines on bomber aircraft. Detect horn-shaped and W-shaped antennas mounted atop BACKTRAP and BACKNET radars. Identify a hand-held SAM (e.g., SA-7/14, REDEYE, STINGER). Identify joints and welds on a TEL or TELAR. Detect winch cables on deck-mounted cranes. Identify windshield wipers on a vehicle.
9	Differentiate cross-slot from single slot heads on aircraft skin panel fasteners. Identify small light-toned ceramic insulators that connect wires of an antenna canopy. Identify vehicle registration numbers (VRNs) on trucks. Identify screws and bolts on missile components. Identify braid of ropes (1 to 3 inches in diameter). Detect individual spikes in railroad ties.

SECTION II. INFRARED NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

NIIRS Rating	Description
0	Interpretability of the imagery is precluded by obscuration, degradation or very poor resolution.
1	Distinguish between runways and taxiways on the basis of size, configuration or pattern at a large airfield. Detect a large (e.g., greater than 1 square kilometer) cleared area in dense forest. Detect large ocean-going vessels (e.g., aircraft carrier, super-tanker, KIROV) in open water. Detect large areas (e.g., greater than 1 square kilometer) of marsh/swamp.
2	Identify individual thermally active engine vents. Detect large aircraft (e.g., C-141, 707, BEAR, CANDID, CLASSIC). Detect individual large buildings (e.g., hospitals, factories) in an urban area. Distinguish between densely wooded, sparsely wooded, and open fields. Identify an SS-25 base by the pattern of buildings and roads. Distinguish between naval and commercial port facilities based on type and configuration of large functional areas.
3	Distinguish between large (e.g., C-141, 707, BEAR, A-300 AIRBUS) and small aircraft (e.g., A-4, FISHBED, L-39). Identify individual thermally active flues running between the boiler hall and smoke stacks at a thermal power plant. Detect a large air warning radar site based on the presence of mounds, revetments, and security fencing. Detect a driver-training track at a ground forces garrison. Identify individual functional areas (e.g., launch sites, electronics area, support area, missile handling area) of an SA-5 launch complex. Distinguish between large (e.g., greater than 200 meter) freighters and tankers.
4	Identify the wing configuration of small fighter aircraft (e.g., FROGFOOT, F-16, FISHBED). Detect a small (e.g., 50 meter square) electrical transformer yard in an urban area. Detect large (e.g., greater than 10-meter diameter) environmental domes at an electronics facility. Detect individual thermally active vehicles in garrison. Detect thermally active SS-25 missile support vans in garrison. Identify individual closed cargo hold hatches on large merchant ships.
5	Distinguish between single-tail (e.g., FLOGGER, F-16, TORNADO) and twin-tailed (e.g., F-15, FLANKER, FOXBAT) fighters. Identify outdoor tennis courts. Identify the metal lattice structure of large (e.g., approximately 75 meter) radio relay towers. Detect armored vehicles in a revetment. Detect a deployed transportable electronics tower at an SA-10 site. Identify the stack shape (e.g., square, round, oval) on large (e.g., greater than 200 meters) merchant ships.
6	Detect wing-mounted stores (i.e., ASM, bombs) protruding from the wings of large bombers (e.g., B-52, BEAR, BADGER). Identify individually thermally active engine vents atop diesel locomotives. Distinguish between a FIX FOUR and FIX SIX site based on antenna pattern and spacing. Distinguish between thermally active tanks and APCs. Distinguish between a 2-rail and 4-rail SA-3 launcher. Identify missile tube hatches on submarines.
7	Distinguish between ground attack and interceptor versions of the MIG-23 FLOGGER based on the shape of the nose. Identify automobiles as sedans or station wagons. Identify antenna dishes (less than 3 meters in diameter) on a radio relay tower. Identify the missile transfer crane on an SA-6 transloader. Distinguish between an SA-2/CSA-1 and a SCUD-B missile transporter when missiles are not loaded. Detect mooring cleats or bollards on piers.
8	Identify the RAM airscoop on the dorsal spine of FISHBED J/K/L. Identify limbs (e.g., arms, legs) on an individual. Identify individual horizontal and vertical ribs on a radar antenna. Detect closed hatches on a tank turret. Distinguish between fuel and oxidizer multi-system propellant transporters based on twin or single fitments on the front of the semi-trailer. Identify individual posts and rails on deck edge life rails.
9	Identify access panels on fighter aircraft. Identify cargo (e.g., shovels, rakes, ladders) in an open bed, light-duty truck. Distinguish between BIRDS EYE and BELL LACE antennas based on the presence or absence of small dipole elements. Identify turret hatch hinges on armored vehicles. Identify individual command guidance strip antennas on an SA-2/CSA-1 missile. Identify individual rungs on bulkhead-mounted ladders.

SECTION III. RADAR NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

NIIRS Rating	Description
0	Interpretability of the imagery is precluded by obscuration, degradation or very poor resolution.
1	Detect the presence of aircraft dispersal parking areas. Detect a large cleared swath in a densely wooded area. Detect, based on presence of piers and warehouses, a port facility. Detect lines of transportation (either road or rail), but do not distinguish between.
2	Detect the presence of large (e.g., BLACKJACK, CAMBER, COCK, 707, 747) bombers or transports. Identify large phased-array radars (e.g., HEN HOUSE, DOG HOUSE) by type. Detect a military installation by building pattern and site configuration. Detect road pattern, fence and hardstand configuration at SSM launch sites (missile silos, launch control silos) within a known ICBM complex. Detect large non-combatant ships (e.g., freighters or tankers) at a known port facility. Identify athletic stadiums.
3	Detect medium-sized aircraft (e.g., FENCER, FLANKER, CURL, COKE, F-15). Identify an ORBITA site on the basis of a 12-meter dish antenna normally mounted on a circular building. Detect vehicle revetments at a ground forces facility. Detect vehicles/pieces of equipment at a SAM, SSM or ABM fixed missile site. Determine the location of the superstructure (e.g., fore, amidships, aft) on a medium-sized freighter. Identify a medium-sized (approx. six track) railroad classification yard.
4	Distinguish between large rotary-wing and medium fixed-wing aircraft (e.g., HALO helicopter vs. CRUSTY transport). Detect recent cable scars between facilities or command posts. Detect individual vehicles in a row at a known motor pool. Distinguish between open and closed sliding roof areas on a single bay garage at a mobile missile base. Identify square bow shape of ROPUCHA class (LST). Detect all rail/road bridges.
5	Count all medium helicopters (e.g., HIND, HIP, HAZE, HOUND, PUMA, WASP9). Detect deployed TWIN EAR antenna. Distinguish between river-crossing equipment and medium/heavy armored vehicles by size and shape (e.g., MTU-20 vs. T-62 MBT). Detect missile support equipment at an SS-25 RTP (e.g., transporter-erector-launcher, missile support van). Distinguish bow shape and length/width differences of SSNs (attack submarines, nuclear). Detect the break between railcars (count railcars).
6	Distinguish between variable and fixed-wing fighter aircraft (e.g., FENCER vs. FLANKER). Distinguish between the BAR LOCK and SIDE NET antennas at a BAR LOCK/SIDE NET acquisition radar site. Distinguish between small support vehicles (e.g., UAZ-69, UAZ-469) and tanks (e.g., T-72, T-80). Identify SS-24 launch triplet at a known location. Distinguish between the raised helicopter deck on a KRESTA II (CG) and the helicopter deck with main deck on a KRESTA I (CG). Identify a vessel by class when singly deployed (e.g., YANKEE I, DELTA I, KRIVAKII FFG). Detect cargo on a railroad flatcar or in a gondola.
7	Identify small fighter aircraft by type (e.g., FISHBED, FITTER, FLOGGER). Distinguish between electronics van trailers (without tractor) and van trucks in garrison. Distinguish, by size and configuration, between a turreted, tracked APC and a medium tank (e.g., BMP-1/2 vs. T-64). Detect a missile on the launcher in an SA-2 launch revetment. Distinguish between bow mounted missile system on KRIVAK I/II and bow mounted gun turret on KRIVAK III. Detect road/street lamps in an urban, residential area or military complex.
8	Distinguish the fuselage difference between a HIND and a HIP helicopter. Distinguish between the FAN SONG E missile control radar and the FAN SONG F based on the number of parabolic dish antennas (three vs. one). Identify the SA-6 transloader when other SA-6 equipment is present. Distinguish limber hole shape and configuration differences between DELTA I and YANKEE I (SSBNs). Identify the dome/vent pattern on rail tank cars.
9	Detect major modifications to large aircraft (e.g., Airings, pods, wingless). Identify the shape of antennas on EW/GCI/ACQ radars as parabolic, parabolic with clipped corners or rectangular. Identify, based on presence or absence of turret, size of gun tube, and chassis configuration, wheeled or tracked APCs by type (e.g., BTR-80, BMP-1/2, MT-LB, M113). Identify the forward fins on an SA-3 missile. Identify individual hatch covers of vertically launched SA-N-6 surface-to-air system. Identify trucks as cab-over-engine or engine-in-front.

SECTION IV. MULTISPECTRAL NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

The traditional OOB criteria categories (air, electronic, ground, missile, and naval) found in the NIIRS are not present in the multispectral imagery (MSI) national imagery interpretability rating scale. Five new categories more relevant to MSI exploitation were developed: military, urban/industrial/lines of communication, vegetation/agricultural, terrain, and water resources.

NIIRS Rating	Description
1	Distinguish between urban and rural areas. Identify a large wetland (greater than 100 acres). Detect meander flood plains (characterized by features such as channel scars, oxbow lakes, meander scrolls). Delineate coastal shoreline. Detect major highway and rail bridges over water (e.g., Golden Gate, Chesapeake Bay). Delineate extent of snow or ice cover.
2	Detect multilane highways. Detect strip mining. Determine water current direction as indicated by color differences (e.g., tributary entering larger water feature, chlorophyll or sediment patterns). Detect timber clear-cutting. Delineate extent of cultivated land. Identify riverine flood plains.
3	Detect vegetation/soil moisture differences along a linear feature (suggesting the presence of a fenceline). Identify major street patterns in urban areas. Identify golf courses. Identify shoreline indications of predominant water currents. Distinguish among residential, commercial, and industrial areas within an urban area. Detect reservoir depletion.
4	Detect recently constructed weapon positions (e.g., tank, artillery, self-propelled gun) based on the presence of revetments, berms, and ground scarring in vegetated areas. Distinguish between two-lane improved and unimproved roads. Detect indications of natural surface airstrip maintenance or improvements (e.g., runway extension, grading, resurfacing, bush removal, vegetation cutting). Detect landslide or rockslide large enough to obstruct a single-lane road. Detect small boats (15–20 feet in length) in open water. Identify areas suitable for use as light fixed-wing aircraft (e.g., Cessna, Piper Cub, Beechcraft) landing strips.
5	Detect automobile in a parking lot. Identify beach terrain suitable for amphibious landing operation. Detect ditch irrigation of beet fields. Detect disruptive or deceptive use of paints or coatings on buildings/structures at a ground forces installation. Detect raw construction materials in ground forces deployment areas (e.g., timber, sand, gravel).
6	Detect summer woodland camouflage netting large enough to cover a tank against a scattered tree background. Detect foot trail through tall grass. Detect navigational channel markers and mooring buoys in water. Detect livestock in open but fenced areas. Detect recently installed minefields in ground forces deployment area based on a regular pattern of disturbed earth or vegetation. Count individual dwellings in subsistence housing areas (e.g., squatter settlements, refugee camps).
7	Distinguish between tanks and three-dimensional tank decoys. Identify individual 55-gallon drums. Detect small marine mammals (e.g., harbor seals) on sand/gravel beaches. Detect underwater pier footings. Detect foxholes by ring of spoil outlining hole. Distinguish individual rows of truck crops.
8–9	Not applicable.

SECTION V. CIVIL NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

The Civil National Imagery Interpretability Rating Scale (NIIRS) supplements the Visible NIIRS by expanding the number of criteria categories.

NIIRS Rating	Description
0	Interpretability of the imagery is precluded by obscuration, degradation or very poor resolution.
1	Distinguish between major land use classes (urban, agricultural, forest, water, barren). Detect a medium sized port facility. Distinguish between runways and taxiways at a large airfield. Identify large area drainage patterns by type (dendritic, trellis, radial).
2	Identify large (greater than 160 acres) center pivot irrigated fields during the growing season. Detect large buildings (hospitals, factories). Identify road patterns, like clover leafs, on major highway systems. Detect icebreaker tracks. Detect the wake from a large (greater than 300 feet) ship.
3	Detect large area (larger than 160 acres) contour plowing. Detect individual houses in residential neighborhoods. Detect trains or strings of standard rolling stock on railroad tracks (not individual cars). Identify inland waterways navigable by barges. Distinguish between natural forest stands and orchards.
4	Identify farm buildings as barns, silos, or residences. Count unoccupied railroad tracks along right-of-way or in a railroad yard. Detect basketball court, tennis court, and volleyball court in urban areas. Identify individual tracks, rail pairs, control towers, and switching points in rail yards. Detect jeep trails through grassland.
5	Identify Christmas tree plantations. Identify individual rail cars by type (gondola, flat, box) and locomotives by type (steam, diesel). Detect open-bay doors of vehicle storage buildings. Identify tents (larger than 2 person) at established recreational camping areas. Distinguish between stands of coniferous and deciduous trees during leafoff condition. Detect large animals (elephants, rhinoceros, and giraffes) in grassland.
6	Detect narcotics intercropping based on texture. Distinguish between row (corn and soybean) crops and small grain (wheat and oats) crops. Identify automobiles as sedans or station wagons. Identify individual telephone and electric poles in residential neighborhoods. Detect foot trails through barren areas.
7	Identify individual mature cotton plants in a known cotton field. Identify individual railroad ties. Detect individual steps on a stairway. Detect stumps and rocks in forest clearings and meadows.
8	Count individual baby pigs. Identify a U.S. Geological Survey benchmark set in a paved surface. Identify grill detailing and/or the license plate on a passenger or truck-type vehicle. Identify individual pine seedlings. Identify individual water lilies on a pond. Identify windshield wipers on a vehicle.
9	Identify individual grain heads on small grain (wheat, oats, and barley). Identify individual barbs on a barbed wire fence. Detect individual spikes in railroad ties. Identify individual bunches of pine needles. Identify an ear tag on large game animals (deer, elk, moose).

APPENDIX C. REQUEST FORMATS FOR AERIAL IMAGERY COLLECTION MISSIONS

Section I. Joint Tactical Air Reconnaissance/ Surveillance (JTAR/S) Request Format

PRECEDENCE

FROM:

TO:

INFO:

CLASSIFICATION

SUBJ: JTAR/S REQ

L. REQUEST NO.___ PREPLANNED IMMEDIATE A. PRIORITY C. PRIORITY B. PRECEDENCE ___

M. DATE/TIME FACTORS

1. DATE MISSION DESIRED

U. REMARKS/SPECIAL INSTRUCTIONS

1. TARGET AREA CONTROL (CALL SIGN/FREQ)_____
2. OTHER (SPECIFY)_____

Notes:
1. Designate minimum mandatory items for immediate requests.
*2. * Indicates use as applicable or when known.*
3. The format provided has been published as STANAG 3277 and has been approved by NATO as a standard format for aerial requests. The letters A to K have special significance for certain organizations and are purposely omitted.
4. When submitting message JTAR/S, the paragraph headings are not required, but the alpha-numeric paragraphs will not be changed.
5. Instructions for completing a JTAR/S are on pages C-4 through C-8.

PARAGRAPH LETTERS INSTRUCTIONS

L. REQUEST NUMBER: As directed.

A&C Priority:	Use numerical designation below to define the tactical urgency for preplanned and immediate requests.
PRIORITY:	It is the responsibility of the requestor to establish the priority.

Priority No.	Definition
1	Takes precedence over all other requests except previously assigned Priority 1 requests. The results of these requests are of paramount importance to the immediate battle situation or objective.
2	The results of these requirements are in support of the general battle situation and will be accomplished as soon as possible after Priority 1 requests. These are requested to gain current battle information.
3	The results of these requests update the intelligence database but do not effect the immediate battle situation.
4	The results of these requests are of a routine nature and will be fulfilled when the reconnaissance effort permits.

M. DATE/TIME FACTORS

1. Self-explanatory.
2. a. State the Time on Target only when required.
   b. Justify U2.
3. Latest time intelligence is of value (LTIOV). Indicate, if it is a factor, the LTIOV. Deliver prior to this date/time.
4. Self-explanatory.

N. TYPE RECONNAISSANCE REQUESTED

1. Type Mission—Self-explanatory.
2. Type Coverage
   a. Pinpoint—Self-explanatory.
   b. Strip/Lines of Communications—Search continuous photography of a route of LOC.
   c. Route Reconnaissance—Visual reconnaissance of a route of LOC with photo of targets of military significance.
   d. Area Search—Visual search of a specified area with photos of targets of military significance.
   e. Area Coverage—Photographic coverage of a specified area.
   f. Afloat—Reconnaissance of vessels afloat.

   3, 4, and 5. Self-explanatory. These lines should be left blank unless it is fully understood what the selected sensor, photo, and film can accomplish.

O. MAP REFERENCE. Self-explanatory.

P. TARGET COORDINATES. Provide reference system used and indicate actual coordinates.

Q. TARGET CATEGORY/PRIORITY INTELLIGENCE REQUIREMENT(S). Provide the appropriate category and indicate the desired PIR by selecting the number(s) from the target list category below.

CATEGORY 1—AIRFIELD

A. Activity: Number, type, and location of aircraft.
B. Runways: Number, orientation, and surface type.
C. Taxiway and parking areas: Location and shape.
D. POL: Number, size, and location.
E. Ammunition storage areas: Number and location.
F. Hangars: Number, size, and type construction.
G. Electronic facilities: Number, type, and location.
H. Defenses: Number, type, and location.
I. Other: (specify).

CATEGORY 2—ARMOR/ARTY/TROOPS/VEHICLES

A. Type: Infantry, armor, engineering, artillery, etc.
B. Number and type of vehicles.
C. Number and type of armor.
D. Number and type of artillery.
E. Activity: Direction of movement, dug in, etc.
F. Terrain: Description.
G. Other: (specify).

CATEGORY 3—BRIDGE

A. Purpose: Flood, rail, over road, etc.
B. Type: Railroad, vehicular, agricultural, etc.
C. Construction: Wood, steel, concrete, etc.
D. Construction: Piers, abutments, approaches, stringers, beam, truss, etc.
E. Number of spans.
F. Length and width (height if significant).
G. Number of lanes/tracks.
H. Bypass in vicinity of bridge.
I. Activity.
J. Other: (specify).

CATEGORY 4—DEFENSIVE POSITIONS/STRONG POINTS/GUNS

A. Type and size of position or fortification.
B. Type weapons: Number.
C. Fire control system.
D. Supporting positions.
E. Transportation access.
F. Routes of ingress and egress.
G. Nature of surrounding terrain and foliage barriers.
H. Activity.
I. Other: (specify).

CATEGORY 5—ELECTRONIC SITE

A. Type site: Microwave relay, EW, etc.
B. Antennas: Number and type.
C. Mobile or permanent.
D. Primary buildings and support equipment.
E. Activity.
F. Security measures.
G. Size of area.
H. Other: (specify).

CATEGORY 6—HARBOR/PORT FACILITIES

A. Type port: Maritime or inland waterway.
B. Activity.
C. Berthing and cargo handling facilities.
D. POL facilities: Type, number, and locations.
E. Storage facilities.
F. Shipbuilding and repair facilities.
G. Transportation.
H. Defenses.
I. Other: (specify).

CATEGORY 7—INDUSTRIAL SITE

A. Type of industry.
B. Size of area.
C. Buildings: Number, size, and construction.
D. Open storage: Quantity by type.
E. Activity.
F. Transportation facilities.
G. Source of power.
H. Defenses.
I. Other: (specify).

CATEGORY 8—LINES OF COMMUNICATIONS (LOC)

A. Type: Road, rail, canal, etc.
B. Description of the route.
C. Chokepoints.

D. Significant activity.
E. Significant static targets.
F. Other: (specify).

CATEGORY 9—MILITARY INSTALLATIONS/STORAGE AREAS

A. Function: Assembly, admin, barracks, depot, etc.
B. Activity: Number of vehicles and/or personnel.
C. Size of the area.
D. Number of buildings: Predominant construction only.
E. Storage: Type and location.
F. Transportation.
G. Defenses.
H. Other: (specify).

CATEGORY 10—MISSILE SITE

A. Type.
B. Launch site: Mobile/fixed, number of pads, etc.
C. Number and orientation of launchers/number loaded.
D. Control center: Location and construction.
E. Number, type, and location antenna(s).
F. Auxiliary equipment.
G. Activity.
H. Defenses.
I. Other: (specify).

CATEGORY 11—POWER PRODUCTION FACILITY

A. Type: Nuclear, coal, oil, hydroelectric, etc.
B. Size and construction.
C. Boiler/generators: Number and location.
D. Transformer yard: Size and location.
E. Cooling towers: Number and location.
F. Penstock/turbine outlet (hydroelectric).
G. Activity.
H. Defenses.
I. Other.

CATEGORY 12—RAILROAD YARD

A. Type: Classification, repair, other.
B. Length and width: Chokepoint to chokepoint.
C. Number of tracks.
D. Facilities: Repair shops, roundhouses, other.
E. Rolling stock.
F. Defenses.
G. Other: (specify).

CATEGORY 13—SHIPS

A. Class/type/number.
B. Heading/movement.
C. Nationality.
D. Identification.
E. Cargo.
F. Activity.
G. Other.

CATEGORY 14—OTHER

Narrative report is rendered under this heading in sufficient detail to ensure that the request or purpose of the mission is satisfied.

R. REPORTS

1. IN-FLIGHT—An in-flight report to friendly units.
2. MISSION REPORT—A mission report of the results and significant sightings gathered.
3. RECONNAISSANCE EXPLOITATION REPORT—A brief, concise, high priority report on time-sensitive targets of significant tactical importance of a perishable nature.
4. INITIAL PHOTOGRAPHIC INTERPRETATION REPORT—An initial photo interpretation report that contains intelligence on mission objectives and additional significant intelligence.
5. SUPPLEMENTAL PHOTOGRAPHIC INTERPRETATION REPORT—A supplemental photo interpretation report that provides detailed intelligence acquired through a comprehensive study of imagery.

S. IMAGERY PRODUCTS—Specify type and quantity of imagery products required. Only mission essential imagery products should be requested.

T. DELIVERY ADDRESS

1. Unit—Delivery address for mission essential imagery products.
2. Air Drop—Coordinates, call sign, frequency, and run-in heading for aerial delivery of imagery products.

U. REMARKS/SPECIAL INSTRUCTIONS

1. Target Area Control—Indicate, when applicable, the call sign and radio frequency of the control element. Control of the mission will require close coordination with ground forces.
2. Other—Self-explanatory (use this space to specify scale if required and to request specific TOT).

Section II. Immediate Joint Tactical Air Reconnaissance/ Surveillance (JTAR/S) Request Format

Source format: Joint Tactical Air Strike Request format.

APPENDIX D. UNMANNED AERIAL VEHICLE SQUADRON EQUIPMENT AND PERFORMANCE CHARACTERISTICS

Pioneer UAV System

The UAV system found in the Marine Corps VMU squadrons consists of the following:

- Pioneer UAV aircraft (see figure D-1).
- Ground control station (GCS) in an S-280 shelter (see figure D-2).
- Tracking control unit (TCU) in an S-250 shelter.
- Portable control station (PCS).
- Remote receiving stations (RRSs) (one to four).
- Rocket-assisted takeoff (RATO) rail and/or truck-mounted pneumatic launchers.
- Arresting gear recovery equipment.

Table D-1 on page D-2 provides Pioneer UAV characteristics.

Figure D-1. Pioneer UAV Aircraft.

Figure D-2. Pioneer UAV Aircraft with GCS.

Table D-1. Pioneer UAV Characteristics.

Altitude	
Service ceiling	15,000 feet
Maximum ceiling	15,000 feet
Endurance	5 to 6.5 hours
Radius of Action	
Nominal	87 nautical miles/160 kilometers
Maximum	101 nautical miles/185 kilometers
Speed	
Maximum speed	176 kilometers per hour/110 knots
Cruise speed	120 kilometers per hour/85 knots
Loiter speed	95 kilometers per hour/65 knots
Maximum endurance	95 kilometers per hour/65 knots
Propulsion Reciprocating Two-Stroke, Two-Cylinder	
Engine	26 horsepower
Fuel type	100-octane, low-lead aviation gasoline/2-stroke oil (50:1 ratio)
Weight	
Empty	125 kilograms/276 pounds
Fuel capacity	30 kilograms/65 pounds
Sensor payload (maximum)	34 kilograms/75 pounds
Maximum takeoff weight	189 kilograms/ 416 pounds
Dimensions	
Wing span	5.2 meters
Wing area	2.8 square meters
Avionics	
Power supply	28 volts direct current
Transponder	mode III identification friend or foe
Navigation	dead reckoning/global positioning system/ground track
Data Link	C-Band and UHF Tadiran/MKD-200/MKD-400 Versatron/DS-12
Sensors	visible light/infrared
Miscellaneous	
Deployment	shipboard—landing platform docks, land based
Launch and recovery	RATO/runway/pneumatic net/runway/hook
Operation	remote control or pre-programmed
Lightning protection system	yes
Releasable imagery	yes
Sensor imagery	C-Band
Command and control	C-Band/UHF

APPENDIX E. MAGTF IMAGERY INTELLIGENCE PLANNING CHECKLIST

This appendix identifies typical IMINT planning actions of the MAGTF G-2/S-2, its IMINT staff, other key G-2/S-2 intelligence staff officers, the intel bn commander/intelligence support coordinator, the imagery intelligence platoon, and subordinate units' intelligence officers during each phase of the MCPP.

MCPP Step	Actions of MAGTF Staff	Actions of MAGTF G-2/S-2 and Intel Bn	
Mission Analysis	Identify the higher headquarters' (HHQ)/supported headquarters' intent. Identify tasks. Determine the AO and AOI. Review available assets and identify personnel and equipment resource shortfalls. Determine constraints and restraints. Determine recommended commander's critical information requirements (priority intelligence requirements, friendly force information requirements, essential elements of friendly information). Identify requests for information. Determine assumptions. Draft the mission statement. Present a mission analysis brief. Draft the warning order. Convene/alert red cell (if appropriate). Begin staff estimates. Refine the commander's intent. Develop the commander's planning guidance.	Review HHQ and MAGTF standing intelligence plans (e.g., Annex B to an OPLAN), pertinent memorandums of understanding, etc. Assist with determination of the MAGTF AO and AOI. Assess NIMA, combatant command's and other external organizations' imagery coverage of the AO and AOI. Provide digital imagery data and other IMINT products to support initial planning (ensure needs of subordinate commands are met). Determine specified, implied, and essential IMINT tasks. Begin development of proposed IMINT concepts of operation; obtain G/S-2 approval. Identify organic/supporting IMINT elements and imagery points of contact in all subordinate units; determine operational status of each; determine personnel and equipment deficiencies (special attention to data management, production, and distribution). Identify JTF/multinational imagery interoperability issues; provide recommendations.	Establish/review/update the MAGTF IPL SOP and database; special attention to— • Identify imagery support requirements. • Prepare imagery data profiles. • Populate IPLs. • Digitize relevant imagery and geospatial products. • Identify external organizations' IMINT production plans and assess against MAGTF's initial requirements; determine deficiencies; initiate augmentation requests (coordinate with intelligence operations officer). • Assign/task-organize organic IMINT elements. • Validate/update JTF IMINT tactics, techniques, and procedures and MAGTF IMINT SOP (coordinate with HHQ and subordinate units). • Validate and prioritize IMINT requirements; special attention to those needed for COA development. • Begin development of IMINT operations plan; issue orders to IMINT production elements (coordinate with P&A cell). • Determine initial IMINT CIS requirements and dissemination plan; identify deficiencies (coordinate with dissemination manager). • Validate IMINT database management procedures (coordinate with JTF). • Ensure subordinate units' IMINT POCs kept advised of actions and developments.

MCPP Step	Actions of MAGTF Staff	Actions of MAGTF G-2/S-2 and Intel Bn	
Course of Action (COA) Development	Continue intelligence preparation of the battlespace (throughout all steps of the planning process). Array friendly forces. Assess relative combat power. Centers of gravity and critical vulnerabilities analysis. Brainstorm possibilities. Develop roughcut COA(s). Commander's input. COA(s) refinement. COA(s) validation. COA(s) graphic and narrative development. Prepare and present COA(s) briefing. Commander selects/modifies COA(s).	Assist with development and continued updating of the intelligence estimate. Develop an IMINT concept of operations for each COA; begin preparation of Appendix 7 (IMINT) and Tab C (UAV and other Aerial Reconnaissance Plans) to Appendix 14 (Recon and Surveillance Plan) to Annex B (Intelligence). Assist the intelligence section and other staff sections with COA development. Determine IMINT capabilities required for each COA.	Assist with the IMINT and related portions of Appendix 11 (Intelligence Estimate), Appendix 14 (Reconnaissance & Surveillance Plan), Appendix 16 (Intelligence Operations Plan), and Appendix 17 (Support to Survival, Evasion, Resistance, and Escape) to Annex B. Assist intelligence section with development of other portions of Annex B. Coordinate production of necessary IMINT products for each COA. Ensure subordinate units' IMINT POCs kept advised of pertinent actions and developments.
COA Analysis	Conduct COA analysis wargaming. Refine staff estimates and estimates of supportability. Develop concepts based upon warfighting functions (as required). Prepare COA analysis brief.	Complete IMINT estimates of supportability. Assist intelligence section with completing the intelligence estimate and the friendly intelligence estimate of supportability. Continue to monitor and update IMINT production operations.	Ensure subordinate units receive necessary IMINT products; verify understanding; identify/update subordinates current IMINT IRs. Validate and update IMINT information requirements. Ensure subordinate units' IMINT POCs kept advised of pertinent actions and developments.
COA Comparison and Decision	Evaluation of each COA. Comparison of COAs. Commander's decision. Issuance of warning order.	Assist intelligence section with evaluation and comparison of each COA. Continue development of Appendix 7 and Tab C to Appendix 14 to Annex B consistent with the selected COA. Continue providing IMINT assistance to appendices 11, 14, 16, and 17 to Annex B. Update, validate, and prioritize IMINT information and production requirements for the selected COA; issue orders as appropriate to IMINT elements. Coordinate IMINT element task-organization needs associated with the selected COA. Validate MAGTF IMINT IRs.	Continue coordination with the G-6/S-6 regarding IMINT CIS requirements; coordinate with G-1/S-1 as necessary for physical couriering of IMINT products to subordinate units. Continue coordination with the G-4/S-4 regarding IMINT supply and transportation requirements. Review actions associated with satisfying IMINT personnel and equipment deficiencies associated with the selected COA. Ensure subordinate units receive pertinent IMINT products; verify understanding; identify/update subordinates' current IMINT IRs. Ensure subordinate units' IMINT POCs kept advised of pertinent actions and developments.
Orders Development	Commander's intent is refined. Concept of operations turned into an operations order or a fragmentary order. Staff estimates and other planning documents are updated and converted into OPORD annexes and appendices. Commander approves OPORD.	Complete development of Appendix 7 and Tab C to Appendix 14 to Annex B; ensure copies provided to subordinate units and are understood. Provide final IMINT support required for Appendices 11, 14, 16, and 17 to Annex B. Update, validate, and prioritize IMINT information requirements and associated collection operations. Maintain coordination with external IMINT organizations.	Ensure pertinent IMINT products are disseminated to all subordinate units. Complete actions associated with personnel and equipment augmentation, interoperability issues, multinational dissemination, etc. Complete IMINT-related CIS, transportation, and supply actions. Monitor ongoing IMINT production operations; update and issue orders as appropriate to IMINT elements.

MCPP Step	Actions of MAGTF Staff	Actions of MAGTF G-2/S-2 and Intel Bn	
Transition	Transition brief Drills Plan refinements (as required)	Assist intelligence section with transition brief. Modify IMINT plans as necessary. Monitor ongoing IMINT collection and production operations; update and issue orders as appropriate to IMINT elements.	Ensure all IMINT POCs in JTF, other components, and subordinate units fully understand plans and standing requirements, and ensure they have received necessary IMINT products. Participate in drills, as appropriate. Remain engaged in MAGTF future plans activities.

APPENDIX F. IMAGERY INTELLIGENCE REPORT FORMATS

Section I. Reconnaissance Exploitation Report (RECCEXREP)

PAGE 1 EXREP 15TH 102 CLASSIFICATION:_____ 831122 03346

(O) PART III. OTHER RESULTS

(P) A. Mission Requirements

(Q) Categorization of Target Entries. An introductory statement categorizing a set of like items to increase readability. DIAM 57-5 contains more detailed information on the structure of part III.

(R) PART IV. COLLECTION OBJECTIVES SATISFIED AND NOT SATISFIED

Explanatory Notes

1. ( ) Shown for explanation only. Line identification is not shown on an actual message.

2. The IPIR/SUPIR/MIPIR format has been revised to accommodate the growth of automated intelligence systems. Detailed definitions and instructions for completing them are included in DIAM 57-05. However, as a user's guide to understanding the reports, the following definitions are provided.

Cable Line

Ref

(A) Self-explanatory

(B) Self-explanatory

(C) Report Type

Reporting Organization

Report Number

Reports will be numbered sequentially by the producing unit. A two-character alpha unit identifier as listed in DIAM 57-5 will be used followed by a four-digit sequential number.

Reconnaissance Project Identification

Two characters indicating the project of which this mission is part. This stands for mission independent. Project identifiers may be derived from DIA reconnaissance program directives or DIAM 57-5-1.

Mission Number

Date/Time Zone

(D) General Mission Statement

Free text reporting information applying to the entire mission such as graphic reference, sensors, sensor on/off times and coordinates, overall image quality, overall image scale range, other general mission data or any other information deemed useful. If the objectives of the mission and the requesting authority can be given (consider length and classification), these will be included. The general mission statement will be written as the interpreted mission and appropriate data will be reported.

(E) Part I. MISSION HIGHLIGHTS

Title for major division of the report.

(F) Textual Data for Mission Highlights.

Part I, Mission Highlights allows for a concise free text statement of the significant information derived from the mission. It may be used to highlight individual items reported

elsewhere in the message and to summarize information relative to a category of targets. Mission Highlights may also be utilized for summations of trends of individual categories such as logistics studies or combat information of a significant nature.

(G) Part II. SIGNIFICANT RESULTS

Title for second major division of the report.

(H) Categories of Items That May be Reported

A—Perishable Items. This section is for items of perishable intelligence value, including transitory targets.
B—New Items. This section is for items upon which the reporting organization has no previous image-derived data.
C—Change and OB Items. This section is for items that reflect significant changes since the last available interpretation and targets, which OB is required. For DOD combat reconnaissance programs, this section includes mission requirement objectives. A mission objective could also be reported under Perishable Items of Damage Assessment.
D—Bonus Items. This section includes significant changes to any known installation that is not a specified mission requirement objective.
E—Damage Assessment. This section is for the description of damage to targets from nonnuclear attacks. This section includes known strike objectives not damaged.

(I) Identification Data.
Item Number.
Basic Encyclopedia (BE) Number or Imagery Basic Encyclopedia Number.
Functional Classification Code. See DIAM 65-3-1.
Installation Name or Description of Object Imaged.

(J) Other Identification Data.
Requirement Number.
Country Code.
Geographic Coordinates.
Universal Transverse Mercator Coordinates.
Military District. Entered when applicable.

(K) Status/Activity Data

NEG. Negated (nonexistent). Target/installation does not exist at or near the coordinates given in the requirement.

UCO. Under Construction.

COM. Complete. The target/installation appears to be externally complete. Appears capable of operating but operational status cannot be determined.

UNK. Unknown. Status of the target cannot be determined.

MOP. Not Operational. Essential elements of a target/installation are observed not to be in operation; equipment essential to the operation of the installation is either missing or observed as not to be operational.

OPR. Operational.

OCC. Occupied.

DEC. Deception.

UNP. Unoccupied.

ABN. Abandoned.

RMV. Removed. Target/Installation has been razed, dismantled or moved.

TRN. Transitory. Fleeting targets or targets that appear to be only temporarily situated.

DMG. Damaged. Target is damaged to some extent, but it may be restored to usable condition.

DST. Destroyed. Target is so damaged that it cannot function as intended or be restored to usable condition.

CNA. Coverage not available.

Exploitation Level

AI -IPIR

AS-SUPIR

MI-MIPIR

Significance

The significance code indicates the interpreter's assessment of the degree of change in the installation status, capability or function since previous mission coverage. If a significance code in entered, the reference mission number and date will be entered. Codes are as follows:

NEW. Newly detected activity.

SIG. Significant change has occurred.

UNK. Significance of change is not known or change, if any, cannot be determined.

NAC. No apparent change.

Reference Graphic

When a national basic reference graphic, exists, the number may be required for certain specific programs. In all other cases, it will be left blank.

(L) Additional Interpretation Data
Additional photo interpretation data will be organized under one of the following codes.

DES. Physical description. A DES will be accomplished when an installation is covered for the first time, a basic description of the installation has not been previously written, the installation reflects a significant physical change, or first reporting an installation as abandoned or destroyed.

RMK. Remarks. This prefix will be used when providing less than a complete description of a known target and/or additional explanatory comments relating to status/activity.

Only a DES or RMK will be used for each entry, not both. If NAC is entered on the status line, a DES will not be used.

The remark will include the project code and mission numbers of the coverages used to prepare the report in those cases where more than one mission is used.

For multiple reporting (MIPIR), the actual OB count will be taken from a representative mission flown during the reporting period.

OOB Designations

MIS. Missile and missile related equipment.

AOB. Air OOB.

NVL. Naval and merchant vessels.

GFW. Ground force weapons and equipment.

ELC. Electronic OOB.

AAA. Antiaircraft OOB.

DMY. Dummy.

OBJ. Associated objects. Information relative to objects and equipment not reported under OOB entries.

Area Delineation

Refers to area delineation of the National Basic Reference Graphic or other descriptive location data. When Unpegs are not available, locational reporting is permitted (e.g., assembly area). Multicoverage dates may be included following each locational entry or as unique entries.

(M) Imagery Reference Data

IMR. Imagery Reference. A minimum of one IMR line is required; however, more lines may be required to indicate different coverage. For MIPIR, only those missions that contributed to a specific degree are entered on the IMR line. Initial information in the IMR line may include date of coverage, project code, mission number, and camera station. The following coded items may then be used.

IMR. Frame number.

SLR. Slide-looking radar.

INF. Thermal.

URG. Universal reference grid. Six position URG coordinates (see DIAM 57-23).

AID. Additional imagery data. AID is used to provide interpretability data. Interpretability codes are as follows:

E-Excellent

G-Good

F-Fair

P-Poor

Extent of Coverage and Mode

A-Complete coverage/stereo

B-Complete coverage/partial stereo

C-Complete coverage/mono

D-Partial coverage/stereo

E-Partial coverage/partial stereo

F-Partial coverage/mono

Type of Coverage

O-Oblique

V-Vertical

Weather Conditions

CL-Clear

SC-Scattered

HC-Heavy Clouds

HA-Haze

Other Conditions

SN-Snow

SH-Shadow

OL-Degrading obliquity

SD-Semidarkness

BL-Blurred image

TR-Terrain masking

HD-Heavy smoke/dust

Type of Film

B-Black and white

C-Natural color

G-Green record

I-Color rear infrared

R-Red record

T-Thermal

S-Radar

N-Nonstandard

(Note: For stereo or partial stereo, two letters will be used, one for the first frame and one for the second frame; e.g., BB, black and white on both frames.)

FRM. Additional frame reference for a given target.

TOT. Time over target.

IDC. Imagery derived coordinates, derived from comparing imagery with a map or chart.

MPR. Map reference.

PPC. Precision photo derived coordinates.

(O) Part III. OTHER RESULTS. Third major division of the report, as indicated by the sample; Part III may be omitted.

(P) A. Mission Requirements. Provides for reporting items/targets not properly placed in Part II.

(Q) Categorization of Target Entries. The format in part IV will contain collection objectives satisfied and not satisfied, plus a textual statement indicating any reasons for non satisfaction. Items contained in part IV can be understood from the codes listed earlier.

(R) Part IV. COLLECTION OBJECTIVES SATISFIED AND NOT SATISFIED. Part IV of the format will contain collection objectives satisfied and not satisfied, plus a textual statement indicating any reasons for non satisfaction. Items contained in part IV can be understood from the codes listed earlier.

APPENDIX G. IMAGERY INTELLIGENCE SUPPORT TO INTELLIGENCE STUDIES

IPB is a systematic, continuous process of analyzing the threat and environment in a specific geographic area. It supports commander and staff estimates and decisionmaking. Applying the IPB process helps the commander selectively apply and maximize combat power at critical points in time and space on the battlefield. When taken in IPB's entirety, imagery plays a small and focused role. However, imagery's role is vital, especially in terrain analysis and mapping tasks.

IMINT Support to Drop Zone Studies

A drop zone (DZ) is a specific area where troops (e.g., a radio reconnaissance team), equipment or supplies are air-dropped. DZs are preplanned locations determined after careful consideration. IAs take on an important role and must consider the following DZ factors:

- Minimum DZ dimensions (DZ length/width computations).
- Maximum slope percentage for DZs is 30 percent.
- Surface and obstacle considerations.
- DZ accessibility and trafficability.
- Easy exit from the DZ.
- Type of aircraft employed.
- Altitude at which air delivery is to be made.
- Types of loads to be delivered.
- Availability of adequate aircraft approach and departure routes.
- Method of airdrop: free drop, high or low velocity.
- Potential approaches and exits.
- Proximity to mission objective.
- Enemy disposition.
- Alternate DZs and landing zones (LZs).
- Supporting fires (in coordination with the G-3/S-3 and the FSC).

DZ Length/Width Computations

The request for DZ identification and supporting intelligence will usually include the rate of speed the aircraft will fly over the proposed area and the amount of time required to deliver a load. The IA (or all-source intelligence analyst) must be informed of the prevailing wind velocity and wind direction, which have an impact on the aircraft's ground speed. When the wind velocity at the delivery altitude cannot be determined, use the aircraft's air speed as the ground speed. Use the steps outlined below to compute the DZ size.

Step 1. Compute the minimum required DZ length by multiplying the ground speed of the aircraft by the time needed to release its cargo.

Length computation formula: L = R x T

L = DZ length (in meters)

S = Aircraft speed in knots

R = Ground speed of aircraft: S x .51

.51 = Conversion factor of knots to meters per second

T = Time required for aircraft to release its cargo and personnel

Step 2. Compute ground speed R

R = (S ± wind speed) x .51

Add tail wind component of wind velocity to aircraft speed or subtract head wind component of wind velocity from aircraft speed (see figure G-1).

Convert knots to meters per second by multiplying aircraft speed by .51.

Step 3. Calculate DZ length (L) by multiplying R x T. The result is in meters. Always round up the required DZ length to the nearest meter.

EXAMPLE: If the aircraft speed is 110 knots, head wind is 20 knots, and drop time is 20 seconds, the required length of the DZ is:

L = R x .51 x T

L = (110 - 20) x .51 x 20 = 918 m

Step 4. Compute required DZ width. The required DZ width depends upon the method and/or type of airdrop, wind drift, and formation of the aircraft, usually provided in the request. When it is not specified, you must give the requester the widths of all proposed DZs that also possess the required length. The wind drift formula is used to determine the minimum required width of a DZ. In this formula, K is a constant that represents the characteristic drift of a certain model parachute. Always round up the required DZ width to the nearest meter.

Wind drift formula: D = K x A x V

D = Width of DZ (in meters)

K = 4.1 (constant) for personnel parachutes

2.6 (constant) for all other parachutes

V = Velocity of surface wind (in knots)

A = Altitude of the aircraft (in hundreds of feet above ground level [AGL])

EXAMPLE: An aircraft flying at 2,000 feet AGL is to drop a cargo load with wind speed of 11 knots.

D = K x A x V

K = 2.6 (G13 cargo parachutes)

V = 11 knots

A = (2,000 ft /100) = 20

D = 2.6 x 11 x 20 = 572 m

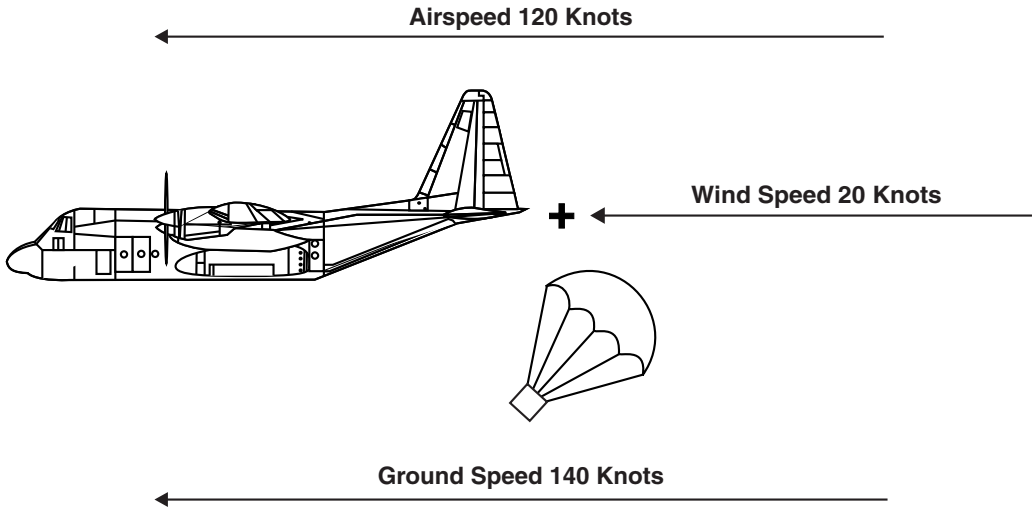

Figure G-1. Prevailing Wind Speed.

Step 5. Now that the required dimensions are known, the IA searches the imagery (or map if imagery is not available) for suitable DZs. Using a photo interpreter (PI) scale or equivalent scale, the IA measures the potential DZ length on the imagery and then computes the ground distance (GD) in meters. Always round down the potential DZ length to the nearest meter.

Imagery length computation formula:
GD = PD x DPRF

Map length computation formula:
GD = MD x DMRF

GD = Ground distance (length) in meters

PD = Photo distance (if in feet, then x .3048 = Conversion factor of feet to meters)

DPRF = Denominator of the photo representative scale

MD = Map distance

DMRF = Denominator of the map representative scale

Scale = 1: DPRF or DMRF

EXAMPLE: An image has a scale of 1:25,000. Using your scale, you measure a potential DZ to be .06 foot.

PD = .06 ft

DPRF = 25,000

GD = .06 ft x 25,000 x .3048 = 457.2 m = 457 m

Step 6. The IA now measures the potential DZ width on the imagery (or map if imagery is not available) and then computes the ground distance in meters the same as in step 5 above. Always round down the potential DZ width to the nearest meter.

EXAMPLE: An image has a scale of 1:25,000. Using your scale you measure a potential DZ to be .04 foot.

PD = .04 ft

DPRF = 25,000

.3048 = Conversion factor of feet to meters

GD = .04 ft x 25,000 x .3048 =
304.8 m = 304 m

Step 7. In those cases where the plot of the potential DZ is irregular in shape, the lengths and widths will be determined as shown in the sketch in figure G-2. The usable length is measured along a centerline while width used is the minimum dimension of the plotted areas with ends perpendicular to the centerline. Width is 140 meters in this example and length is 380 meters.

Step 8. Compute flight time. For safety requirements, a DZ should be as large or larger than the commander's request. Normally an area 460 meters long and 180 meters wide is the minimum requirement for the delivery of supplies. If a DZ of the desired length is not available, the flight time over the DZ (whatever its length) must be computed to determine how much of the load can be released in

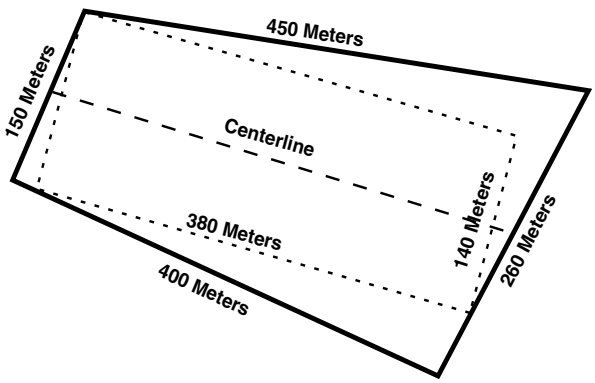

Figure G-2. Irregular-Shaped DZ.

one pass and/or how many passes must be made to release the entire load. Always round the flight time down to the next lower whole second.

Flight time computation formula: $T = \frac{L}{R \times .51}$

T = Time over the DZ in seconds

L = Length of the DZ in meters

R = Aircraft ground speed in knots

.51 = Conversion factor of knots to meters per second

EXAMPLE: An aircraft is flying at 105 knots over a DZ that measures 150 meters long.

L = 150 m

R = 105 knots x .51 = 53.55 = 53 m/seconds

$T = \frac{150}{(105 \times .51)} = \frac{150}{53} = 2.83 = 2$ seconds

Slope Calculations

After the DZ area has been determined, the IA computes the slope. For this task a map of the area is required. The slope of a DZ should not be more than 30 percent. Always round up the slope to the nearest percent. Both vertical distance (VD) and horizontal distance (HD) must use the same unit of measurement (feet or meters). Use 3.281 as the conversion factor from meters to feet or .3048 to convert feet to meters. Use the following formula to compute the terrain's slope, which will be expressed as a percentage:

$SL = \frac{VD}{HD} \times 100$

SL = Percent of slope

VD = Vertical distance of the DZ (altitude difference between each end of the DZ length)

HD = Horizontal distance of the DZ

100 = Conversion factor for percent

EXAMPLE: The length of the DZ is 900 meters, one end is at an altitude of 150 feet and the other end at 200 feet, the percent of slope is 1.7%, rounded up to 2%.

$SL = \frac{(200\ 150)}{(900 \times 3.281)} \times 100 = 1.7\% = 2\%$

The contour intervals on maps are in feet or meters. The bar scales are usually in meters, yards, statute miles or nautical miles. If the bar scale is used, a conversion from one unit of measure to another may have to be performed. If a Pl scale is used, be sure to multiply the measurements by the map scale. To determine slope using a map, refer to the following steps and figure G-3 on page G-5 and figure G-4 on page G-6.

Step 1. Determine the elevation of each point. Neither point is on a contour line, so it will be necessary to interpolate. Point Y is located on an intermittent stream symbol, confused with a contour line if care is not taken. The contour interval is 50 feet.

Step 2. Measure the distance between points X and Y using a piece of paper, Pl scale or boxwood scale. Make measurements from the center of one dot to the center of the other dot (see figure G-4 on page G-6). A tube magnifier may be required to exactly align the scale with the centers of the two points to accurately determine the distance found.

In figure G-4 on page G-6, the map distance (MD) is 2.95 centimeters (cm). GD is found by solving the following formula:

GD = MD x DMRF, the latter of which is 50,000

GD = 2.95 cm x 50,000 = 147,500 cm = 1,475 m

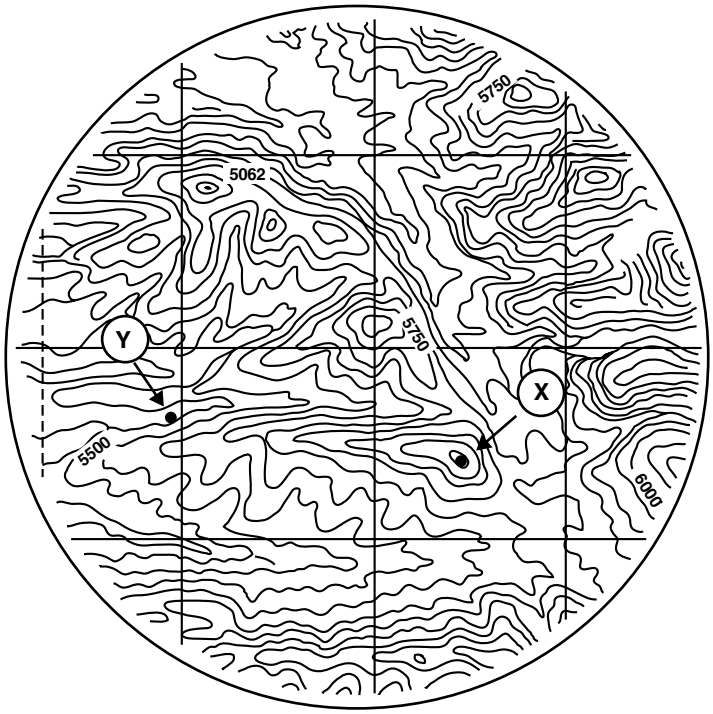

Figure G-3. Map Extract (map not to scale).

In comparing elevations and horizontal distance, elevation is in feet and distance in meters, so a conversion from one to the other is required.

GD = 1,475 m x 3.281 ft/m =
4,839.475 (rounded up to 4,840 ft)

Step 3. Use the slope formula:

VD = change in elevation from point V to point Y

$$SL = \frac{VD}{HD} \times 100 = \frac{X\ Y}{HD} \times 100$$

EXAMPLE: A DZ with a length of 4,840 feet has elevations of 5,925 feet and 5,475 feet.

$$SL = \frac{5{,}925 \text{ ft } 5{,}475 \text{ ft}}{4{,}840 \text{ ft}} \times 100$$

$$SL = \frac{450}{4{,}840} \times 100 = 9.2975; \text{ rounded up to } 10\%$$

SL = 10%

Surface and Obstacle Considerations

When both size and slope of a proposed DZ are acceptable, inspect imagery of the area for the presence of obstacles and potentially hazardous surface conditions. This requires examination of photography in stereoscopic pairs as well as a review of available maps. Two major reasons for the examination of imagery are to protect troops from injury during a drop and to prevent the unsuccessful drop of equipment. The most acceptable DZ is a flat, resilient surface without obstructions.

Unfavorable or hazardous surface conditions are normally provided by the terrain detachment, to include information on—

- Water.
- Marshland.
- Gullies.
- Drop-offs (cliffs).
- Dense trees.
- Dense low vegetation.
- Large rocks.

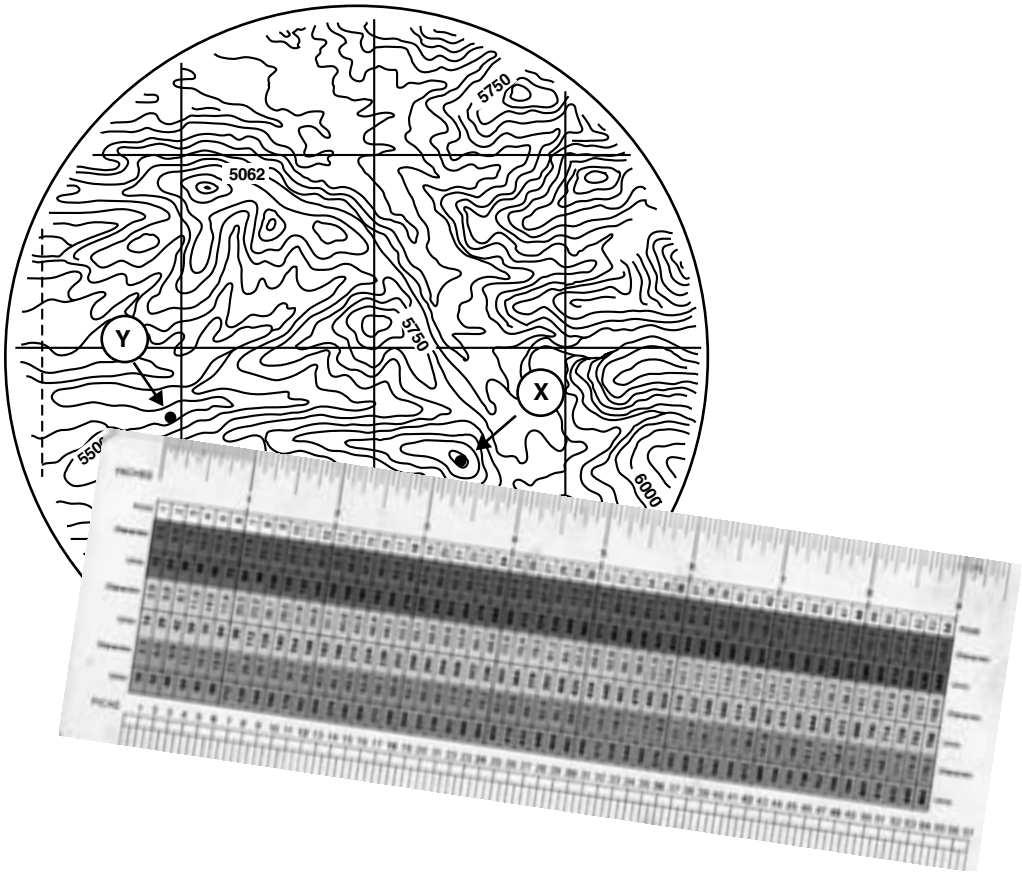

Figure G-4. Measuring from Dot to Dot (map not to scale).

Obstacles that are manmade features, such as—

- Power lines and poles.
- Buildings.
- Towers.
- Fences.
- Military impediments (e.g., stakes, barriers, barbed wire).

DZ Accessibility and Trafficability

A favorable DZ must have easy accessibility for both approach and exit. If possible, DZs near LOCs should be selected.

Certain questions must be answered before identification can occur; the tactical situation will add other questions:

- Will the approach involve more or less troops and equipment than the exit?
- Will the exit involve more or less troops and equipment than the approach?
- Will the approach or exit occur during daylight or night?

When troops are parachuted into a DZ, it is important they have an easy exit. The exit should be in the general direction supporting the ground tactical plan. When supplies or equipment comprise the load, personnel on the ground must be able to approach the area, recover the material, and then exit with the material. When evaluating a potential DZ for accessibility, the type of load will be a major consideration.

EXAMPLE: If wheeled vehicles are parachuted into a DZ, troops on the ground may be able to approach the DZ through a densely wooded area or up a steep slope. However, the vehicles may not be able to exit through the forest or negotiate the slope.

Related to accessibility is the trafficability of the soil. Swampy soil, or in some cases fine sand, may rule out the selection of a DZ. The parachuted equipment may bog down or troops may not be able to approach or exit the area rapidly. Therefore, trafficability of access routes must be considered to afford easy cross-country movement of vehicles and personnel in and out of the DZ.

DZ Reports and Overlays

Normally, the IA assists all-source intelligence and geographic intelligence (GEOINT) analysts with preparing a report in accordance with local SOPs. A primary DZ and alternate DZs will be selected that meet the specified intelligence requirements. This information is provided to the P&A cell OIC, who in turn recommends these to the ISC and G-2. Upon request, an overlay of the primary and alternate DZs will be prepared. GEOINT analysts generally will prepare this overlay.

IMINT Support to Helicopter Landing Zones Studies

A helicopter landing zone (HLZ) is a specified ground area for landing assault helicopters to embark or disembark troops and/or cargo. An LZ may contain one or more landing sites. Primary and alternate HLZs that meet the IRs will be identified, analyzed, and provided to the supported ground unit and aviation commanders. The ground unit commander (or helicopter unit commander) in coordination with the supporting air mission commander (AMC) will select the final location of the HLZ to best support the ground tactical plan.

General HLZ Criteria

In selecting an HLZ from maps, aerial photographs, and actual ground or aerial reconnaissance, the same criteria used for determining a DZ apply. Additional information, normally supplied by the ACE commander or AMC, should be used when selecting an HLZ. Information should include the type of HLZ and type and the number of helicopters used. HLZs have the following specifications:

- An HLZ is a helicopter landing area that encompasses one or more helicopter landing sites.
- A helicopter landing site is a subdivision of an HLZ. The size of a landing site depends on the number of landing points (LPs) and the size of the LPs.
- An LP is a designated or selected touchdown point where a single helicopter lands.

As previously stated, the size of the landing site will depend on the number of LPs within it, and the size of these LPs. As a guide, a helicopter requires a relatively level, cleared, circular area of 20 to 75 meters in diameter, depending on the type of helicopter. A helicopter requires more usable landing area at night than during the day. The criteria provided in figures G-5 on page G-8, G-6 on page G-8, and G-7 on page G-9, represent guidance on LP preparation. Helicopter units will designate the size (small, medium or large) to be used by their units for specific operations. Numerous considerations such as helicopter type, unit proficiency, nature of loads, and weather conditions may apply to size of LPs used. General distances between LPs within a landing site in daytime landing are as follows (measured center to center):

- Small landing points 80 feet, or 25 meters.
- Medium landing points 115 feet, or 35 meters.
- Large landing points 165 feet, or 50 meters.

Most helicopters cannot land or take off vertically when they are fully loaded; therefore, a larger area or a better approach is needed.

The ACE commander has the final authority in establishing the landing area criteria for assigned helicopters in daytime and nighttime missions. This may change from time to time, depending on how heavily loaded the aircraft will be, the place and time of landing, and the anticipated weather conditions. During specific missions, the

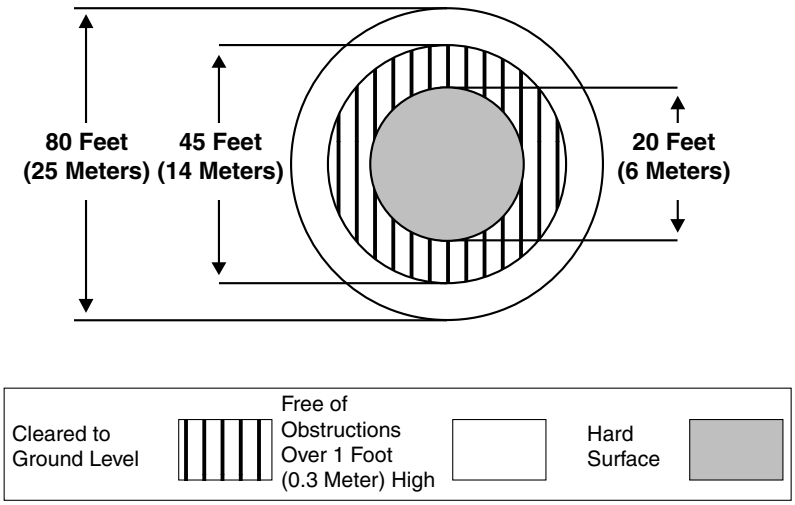

Figure G-5. Small Landing Point Dimensions.

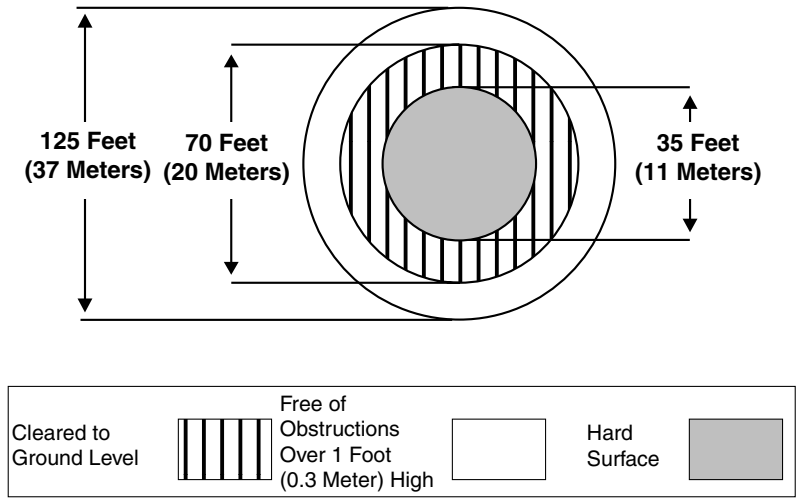

Figure G-6. Medium Landing Point Dimensions.

AMC may exercise this authority. For example, the area requirement may be larger when—

- A helicopter is heavily loaded.
- Helicopter cargo is sling loaded.
- Landing must be made at night or during other periods of reduced visibility.
- There are terrain obstructions or obstacles in the area.
- An area is located at high elevation.
- Temperature is hot or when humidity is high.

The ACE commander or AMC should provide the G-2 or ISC with required dimensions for all HLZs based on various flight and landing formations. This action will assist the IA and all-source intelligence analyst in locating potential HLZs.

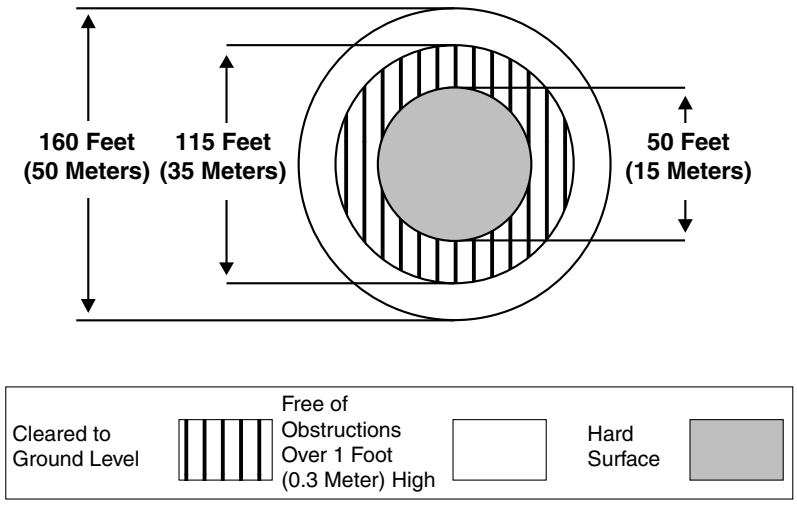

Figure G-7. Large Landing Point Dimensions.

HLZ Computations

In determining the HLZ area size, proceed in the same manner as for the DZ area. First, compute the required and then the potential HLZ areas. To determine the HLZ area, use the procedures shown below.

Step 1. Determine HLZ dimensions on photographs or maps. If the results are in fractions, round down to the nearest foot or meter. Use the same basis for all measurements (either feet or meters). FORMULA:

Potential HLZ length when measuring:

- Imagery: GD = PD x DPRF
- On a map: GD = MD x DMRF

Potential HLZ width when measuring:

- Imagery: GD = PD x DPRF
- On a map: GD = MD x DMRF

Step 2. Determine how may helicopters can land in the potential HLZ area in a two-trail formation during daytime. Round up converted LP dimensions.

Step 3. Determine the number of LPs (or helicopters) from front to rear of the potential HLZ. Round down number of helicopters. FORMULA:

LPs from front to rear = Potential HLZ length
Minimum recommended LP length

Step 4. Determine number of lateral LPs of the potential HLZ. FORMULA:

Lateral LPs = Potential HLZ width
Minimum recommended LP width

Step 5. Determine the total number of helicopters LPs of the potential HLZ. FORMULA:

Total # helicopter LPs = # of LPs from front to rear x # of lateral LPs

Slope Computations

The slope for an HLZ should not exceed 8 percent if the helicopter is to land. However, at the pilot's discretion it may be possible for a helicopter to hover just in contact with the ground on slopes greater than 8 percent.

When you compute the slope, do not depend entirely on the map. Study the area on imagery, too.

The map contour intervals may indicate that the percent of slope is sufficient, but sloping or rugged terrain can be seen only with a stereoscope.

When the slope is greater than the allowable 8 percent, report this to the requester. The site may still be usable if the commander chooses to hover the aircraft and load/unload troops and supplies by rope or ladder. When the slope is more than 8 percent, provide the requester with the exact percent figure so he can assess alternatives and decide. This is important because when the ground slope is less than 8 percent, helicopters should be landed up-slope. When the slope is more than 8 percent, helicopters should land side-slope. See figure G-8.

Now you are ready to compute the slope of each potential HLZ. Do this the same way as the DZs using the formula:

$$SL = \frac{VD}{HD} \times 100$$

When you compute the HLZ slope, consider the following:

- Direction of positive slope. This is important for the approach and exit direction.
- Number of aircraft used. The AMC will provide this information.
- The density altitude. The altitude, temperature, and humidity determine the density altitude (DA). For planning purposes, as DA increases, the landing area should increase proportionately.
- Approach/departure directions. When possible, approach and departure should be into the wind. However, if there is only one suitable approach direction due to obstacles, the tactical situation, or if it is desired to make maximum use of the available HLZ, most helicopters can land with a crosswind (10 knots or less) or a tailwind (5 knots or less). The same applies to departures from the HLZ.
- Loads. When fully loaded, most helicopters cannot ascend or descend vertically.

Aircraft Landing Zone

An aircraft LZ (also referred to as runway or landing strip) is a specified location used for landing aircraft. Potential aircraft landing zones are selected to meet the intelligence requirements of the supported ground and aviation units' commanders. Potential aircraft LZ locations will be identified and analyzed based on aerial imagery, current maps, and other available intelligence.

Aircraft Landing Zone Criteria

An aircraft LZ is established so aircraft can safely land and take off. It also provides guidance for aircraft while they are taxiing and parking. It has one or more landing strips. The landing strip consists of a runway and may include taxiways, parking points, and dispersal areas. Selection of a potential aircraft LZ depends on the type aircraft, runway dimension requirements (see table G-1), surface, and location.

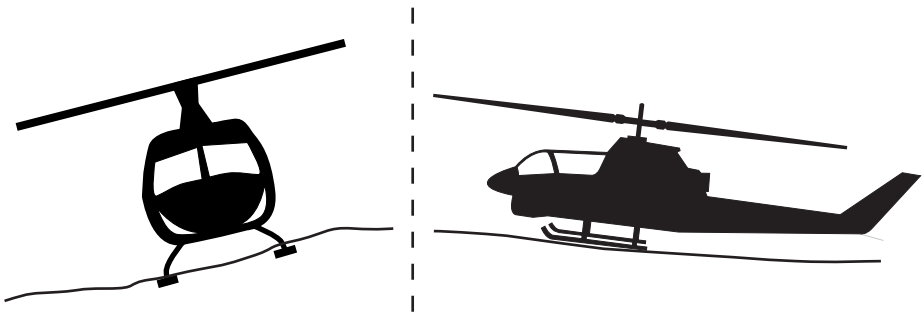

Figure G-8. Helicopter Landing on Side-Slope and Up-Slope.

Table G-1. Runway Dimension Requirements.

	Airfield Type	Runway Length (in feet)	Runway Width (in feet)	Runway Shoulder (in feet)
Forward Area	Attack & Utility	N/A	N/A	N/A
	Vertical	N/A	N/A	N/A
	Light Lift	1,200	60	10
	Medium Lift	2,500	80	10
Support Area	Attack & Utility	N/A	N/A	N/A
	Vertical Lift	N/A	N/A	N/A
	Light Lift	1,500	60	10
	Medium Lift	3,500	60	10
	Heavy Lift	6,000	100	10
	Tactical	5,000	60	4
Rear Area	Medium Lift	6,000	72	10
	Heavy Lift	10,000	156	10
	Tactical	8,000	108	20

Airfield Type

There are two types of aircraft landing zones, classified according to their size and degree of improvement:

A hasty landing strip has an unimproved surface, which normally is acceptable for marginal weather, but is unusable during prolonged poor weather. After a period of occupation, most pioneer landing strips (terrain permitting) can be improved to meet the requirements of a hasty landing strip. This strip has the following characteristics:

- Minimum length: 3,000 feet, plus a 10 percent overrun at each end.
- Minimum width: 50 feet, plus a 10 feet shoulder on each side.
- Minimum lateral clearance: 100 feet on each side of runway centerline.
- Has taxiways, parking areas, and may include dispersal areas.

A deliberate landing strip has an all-weather capability. As a minimum, it should have all the characteristics of a hasty landing strip, plus any other facilities needed to meet the standards required by any aircraft. A deliberate strip is usually a permanent installation with a control tower, hard surface runways, taxiways, and parking ramps.

Aircraft Landing Zone Computations

To determine the length and width of the area, use the same formula as for measuring a DZ or HLZ. Then identify the potential aircraft LZ by type.

EXAMPLE: If the photo scale is 1:20,000, the photo distance (length) is .08 feet and the photo distance (width) is .004 feet, then the potential aircraft LZ could be either a hasty or deliberate type depending on construction and facilities.

Slope Computations

In computing the slope (SL), the maximum slope for a potential aircraft LZ should not exceed 10 percent. Always round slope up to the nearest percent. Use the same formula as for computing SL of a DZ or HLZ:

$$\text{SL (expressed as a percentage)} = \frac{\text{VD}}{\text{HD}} \times 100$$

Surface and Obstacle Considerations

The surface of a potential aircraft LZ must be firm and smooth enough to allow heavily loaded aircraft to land, taxi, park, and take off without delay or damage to the aircraft. It should be located away from obstacles such as mountains, telephone wires, tall buildings, and trees. The area should be free of heavy rocks and stumps so troops can clear it easily. This is particularly important for pioneer and hasty strips, which may have to be established quickly. The area should be dry, as water or marshland can cause early erosion.

LZ Accessibility

An aircraft LZ should have convenient access to and from the area, such as roadways or other level terrain. If there are prevailing winds, the runway should be oriented, if possible, so that aircraft can land and take off into the wind.

The minimum size of an aircraft LZ depends on the type of loads, the direction and velocity of winds, and the condition of the ground. Consider the following factors in establishing an aircraft LZ:

- Soft, wet, slippery or any other unfavorable surface conditions will increase the length of the aircraft LZ.
- Crosswinds may require an increase in width of the aircraft LZ.
- Uphill take off and downhill landings will require longer runways. The maximum slope on any aircraft LZ should not exceed 10 percent.
- Obstacle clearance is measured from the obstacle to the approach and departure end (if there are obstacles at the approach and departure ends of the aircraft LZ). Ensure a 10:1 clearance ratio is obtained (same as used for an HLZ).

Aircraft Landing Zones Overlays

Per the intelligence production requirement, all-source intelligence analysts, assisted by IAs and GEOINT analysts, will prepare an overlay of the potential primary aircraft landing zone and an alternate aircraft LZ if deemed necessary. A relief and drainage overlay may also be provided. Aircraft LZs are normally referred to by their nickname or a color. Situation and time permitting, GEOINT analysts will prepare this overlay.

IMINT Support to Beaches Studies

A beach is the area extending from the shoreline inland to a marked change in physiographic form or material or to the line of permanent vegetation. In amphibious operations, a beach is that portion of the shoreline designated for landing of a tactical organization. A landing beach is that portion of a shoreline usually required for the landing of a battalion landing team. However, it may also be that portion of a shoreline constituting a tactical

locality (such as the shore of a bay) over which a force larger or smaller than a battalion landing team may be landed. A beach landing site (BLS) is a geographic location selected for across-the-beach infiltration, exfiltration or resupply operations. A beachhead is a designated area on a hostile or potentially hostile shore that, when seized and held, ensures the continuous landing of troops and materiel, and provides maneuver space requisite for subsequent projected operations ashore. Finally, a landing area is the part of the objective area within which are conducted the landing operations of an amphibious force. It includes the beach, the approaches to the beach, the transport areas, the fire support areas, the air occupied by close supporting aircraft, and the land included in the advance inland to the initial objective.

Beach Landing Site Factors

A BLS is a continuous segment of coastline over which troops, equipment, and supplies can be landed by surface means.

Primary and alternate BLS are selected and prioritized after considering the commander's intent and guidance, concept of operations and scheme of maneuver, enemy disposition, size of the area required, terrain features, weather factors, supporting fire, and proximity of the objectives. Amphibious operations require a detailed study of hydrography, weather, climate, and terrain. The terrain portion is primarily the responsibility of MAGTF GEOINT analysts. A tactical study of the terrain is prepared by all-source intelligence analysts with major assistance from IAs and GEOINT analysts. (See MCWP 2-12, *Intelligence Production and Analysis*, and MCWP 2-12.1, *Geographic Intelligence*, for additional information on tactical studies of the terrain.)

The landing force commander selects specific landing beaches from available beach landing sites. When the amphibious task force is composed of two or more attack groups with related landing groups, a landing area may be selected for each attack group. In this case, each landing group commander selects the landing beaches from within the assigned area.

The principal factors in the selection of landing beaches are—

- Suitability for beaching landing ships, landing craft, and amphibious vehicles.
- Beach trafficability.
- Suitability of offshore approaches.
- Number, location, and suitability of beach support areas and beach exits.
- Location, type, and density of beach obstacles, including underwater obstacles.
- Nature of the terrain immediately inland from the beaches.
- Suitability of LOCs, including roads, railroads, and waterways.
- Suitability of the beach from the standpoint of expected weather and tidal conditions.
- Known hostile force dispositions, strengths, and capabilities.

Beaches are categorized by their shape (see figure G-9 on page G-14):

- Concave (Point A to Point B).
- Convex (Point B to Point C).
- Straight (Point C to Point D).
- Irregular (Point A to Point D).

Beach types include the following:

- Coastal plain.
- Coastal ridge.
- Cliff or terrace.
- Coral reef.
- Glacial.
- River mouth or delta.
- Pocket.

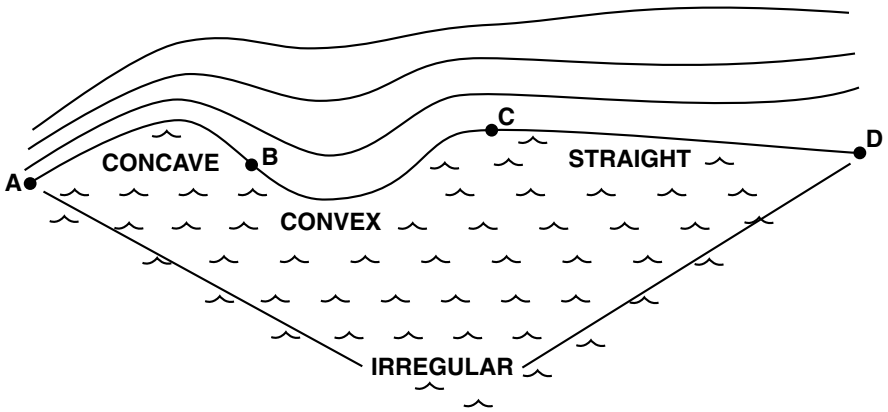

Figure G-9. Beach Catagories.

Coastal Plain Beaches

A landing on a wide coastal plain beach provides unrestricted maneuver room, and a subsequent advance from the beach can be made in any direction. Boundaries and objectives are more difficult to locate on this type of terrain; there are few prominent registration points for artillery, naval gunfire, and aerial bombardment. Usually there is no natural defensive terrain on the flanks of the beachhead, so more troops are required to protect the flanks. Some coastal plain beaches are near marshy and swampy terrain, which may hinder movement from the beach.

Coastal Ridge Beach

A coastal ridge beach has terrain that rises evenly to a considerable distance back from the beach that gives the defender excellent observation and fields of fire. More commonly, the coastal area remains flat for some distance and then rises in a steep gradient to a coastal ridge.

Cliff or Terrace Beach

A cliff or terrace beach is usually quite narrow. The delineation of a cliff beach from a terrace beach basically is established by the height of the landmass immediately behind the beach. Cliff beaches may have rocks and debris that accumulate by erosion of the adjoining severe terrain. The surface is made up of the same type of material as the major adjacent landform. If wave action is strong on a cliff beach, any fine material is washed away resulting in a beach covered with boulders or barren rock. Cliff beaches isolated from strong wave action are usually composed of sand and similar to coastal plain beaches as far as surface materials are concerned. A terrace beach may be composed of loose sand or rocks; it may be barren rock or strewn with boulders.

Coral Reef Beach

A coral reef beach is located in the coral region (normally between 30 degrees north latitude and 30 degrees south latitude) protected by a barrier reef with fringing reef along the shoreline, or it is located on an atoll. Any beach protected by a barrier reef is composed primarily of fine coral sand (coral skeletal remains, broken shells, and hardened algae) and is usually firm and narrow. When the beach or fringing reef is exposed to wave action, the foreshore is eroded. The coral reefs themselves normally present significant obstacles with abrupt seaward slope and the exposed offshore edge of the reef is steep. The upper surface of the reef may be extremely rough with

jagged coral formations rising above the surface and deep pits indenting the surface of the reef. An atoll is a ring-shaped coral island or group of coral islands enclosing a lagoon or another island. It has the same basic characteristics as the coral barrier reef.

Glacial Beaches

Glacial beaches are usually found in the higher latitudes, normally above 60 degrees north and 60 degrees south latitude. These beaches were eroded by glacial action and have round and irregular shorelines with numerous inlets; some may be quite deep, long, and narrow, with almost perpendicular, smooth mountain walls rising to great heights. This type of coast is very dangerous to navigation because of the islands and rocks off entrances to the inlets. The beach may be composed of material that has no geologic relationship to the coastline with depositions of material carried from the hinterland by the glaciers. This is often a mixture of silt, sand, gravel, and rocks.

River Mouth or Delta Beach

This type beach is easy to identify due to its proximity to the mouth of a major stream or river. It undergoes a greater physical change than the other beach types, and the foreshore is composed primarily of the type of sediment carried by the stream or river.

Pocket Beach

A pocket beach is found on many of the coasts throughout the world and has a wide range of composition and topography. The irregular coastlines, where pocket beaches are quite common, are made up of headlands and indentations with the pocket beaches found in the indentations. This type of beach is divided into two general areas: the end zones and central zone.

- The end zones are those areas on the flanks inside the beach termination points. They are protected from direct wave action by the headlands and subsequently the beach soil is usually fine sand.
- The central zone is that portion of the entire beach between the end zones and exhibits the same characteristics and soil conditions of any beach exposed to wave action. Any highlands behind the beach may provide the source material continually washed down and deposited on the beach. Lowlands behind the beach, however, will have little effect on its character.

A common problem affecting some pocket beaches is that many of the bays or other indentations fronting the beach may become blocked by sandbars built up by sand drifting along the coast in long shore currents. These sandbars may become attached to the mainland at the upstream end, and any open channel that might exist will occur at the downstream end. Sometimes these sandbars connect offshore islands to the mainland. Pocket beaches are usually concave shaped.

Beach Landing Site Criteria

The required beach area for amphibious operations is calculated based on original requester's guidance, type forces conducting the ship-to-shore maneuver, local SOPs and METT-T.

To identify whether an area is suitable for beach landings, intelligence analysts will require the following information:

- Minimum length of beachfront necessary.
- Types of equipment being landed.
- Types of transports to be used, to include length and width of each transport type.
- Transport capability. (Can it land on the beach? What minimum depth [draft] is required?)

Beach Landing Site Computations

Beach landing length is computed using the formula GD = PD x DPRF similarly as for DZs, HLZs, and aircraft LZs. Measurements are taken from one termination point to another (see figure G-10) and rounded down to the nearest meter.

- The beach termination points are the extreme ends of the beach selected. The total length of the beach is measured between these points following the natural coastline.
- The beach width is the horizontal dimensions of the beach measured at right angles to the shoreline from the line of extreme low water inland to the landward limit of the beach (the coastline). It usually will not be uniform and, therefore, is determined at various points along the beach.
- The beachhead line, roughly semicircular, encompasses that area near the coast large enough for the deployment of the assault force and its supplies and equipment, and usually includes terrain features that are the initial objectives of the assault force. The beachhead line, if established, must be held so the subsequent landing forces can land and deploy in proper battle order. Loss of or major enemy force penetration into the beachhead line places the entire amphibious operation in jeopardy.
- The beachfront extends from low tide limit to the high tide limit and usually coincides with the foreshore (see figure G-11).

Percent of Slope and Gradient Computations

Use the same formula as for determining percent of slope of a DZ, HLZ or aircraft LZ with different specifications. Measurements are made of the width of the beachfront. Always round up percent of slope to the nearest percent.

$$SL = \frac{VD}{HD} \times 100$$

SL = Percent of slope

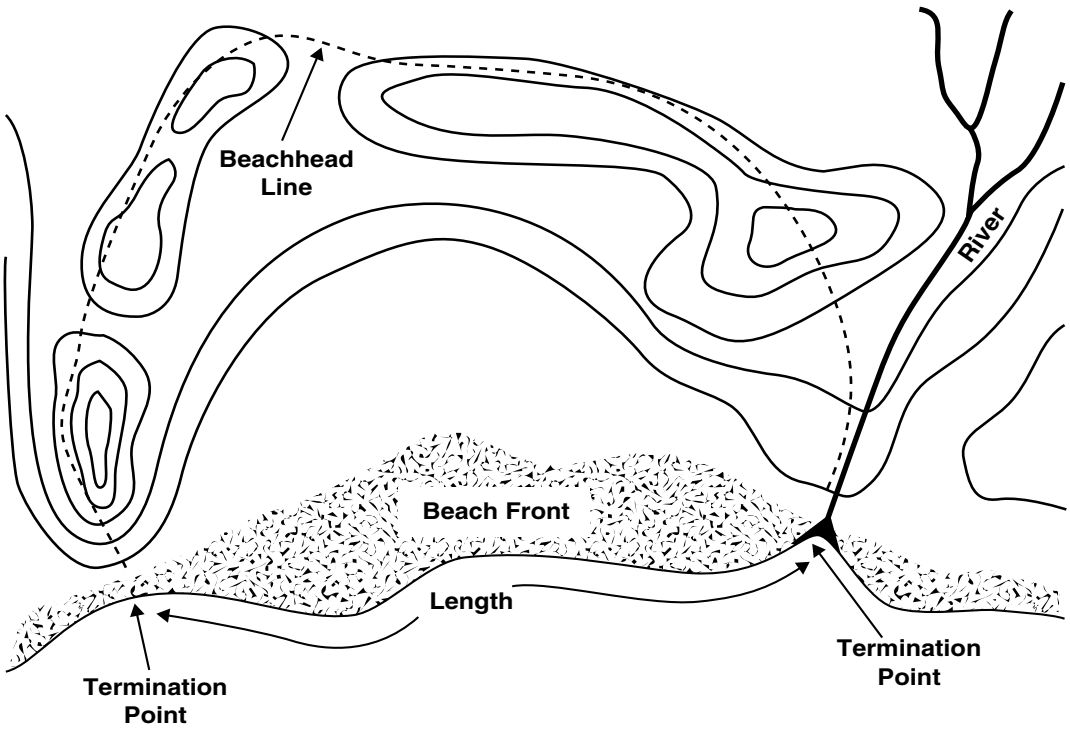

Figure G-10. Landing Beach Length.

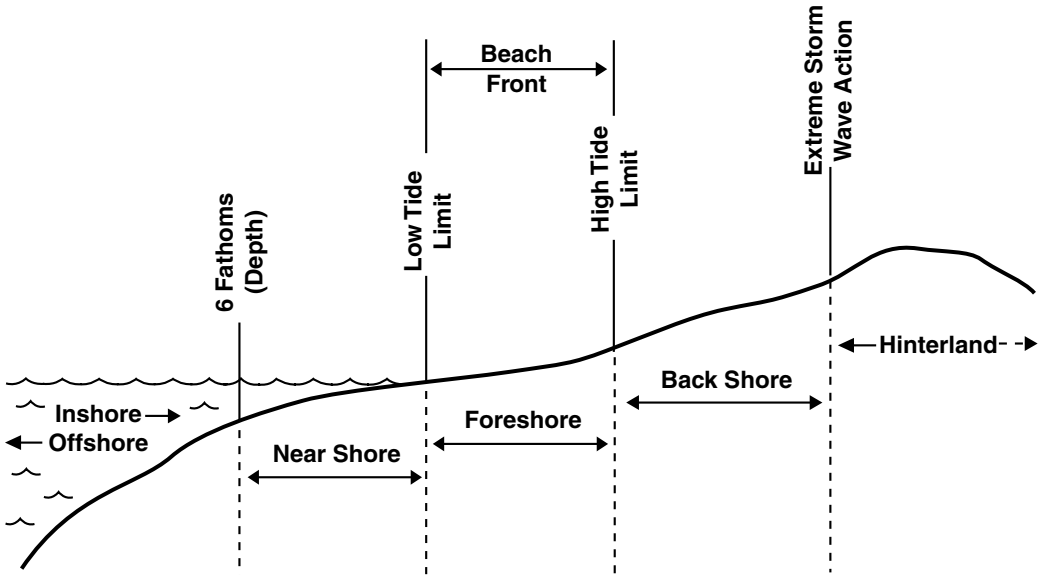

Figure G-11. Shores.

VD = The height difference of the beachfront, which is from the edge of the beachfront (low tide limit) to the high tide limit.

HD = The horizontal (ground) distance of the beachfront.

Combined offshore or foreshore/back shore beach gradient is expressed as a ratio of the rise in elevation of one unit of measure to the horizontal (ground) distance in a number of the same unit of measure; e.g., 1:15.

FORMULA:

$$\text{Gradient} = \frac{VD}{HD}$$

A quick way to obtain the gradient (1:) is to invert the fraction and divide the denominator by the numerator. Round up any fractions to the next whole number (e.g., 1:50.52 = 1:51).

EXAMPLE: If VD = 150 m and HD = 3,000 m

$$\text{Gradient} = 1: \frac{3{,}000}{150} = 1:20$$

In computing the combined foreshore/back shore gradient, measure from the shoreline to the nearest 20 meter contour line used for the start of the hinterland. You should transfer the 20 meter contour line from the map to the photograph by interpolation prior to making your measurement. The gradient is further expressed as shown in table G-2.

Table G-2. Beach Gradients.

Less than 1:120	Flat
1:120 to 1:60	Mild
1:59 to 1:30	Gentle
1:29 to 1:15	Moderate
1:14 or more	Steep

The depth lines or curves illustrated at 1, 2, and 3 fathoms (1 fathom = 6 feet) (see figure G-12 on page G-18) are established to determine the offshore gradient and to assist in the safe approach of the landing craft. The depth curves may be a series of dots (as shown) or solid lines.

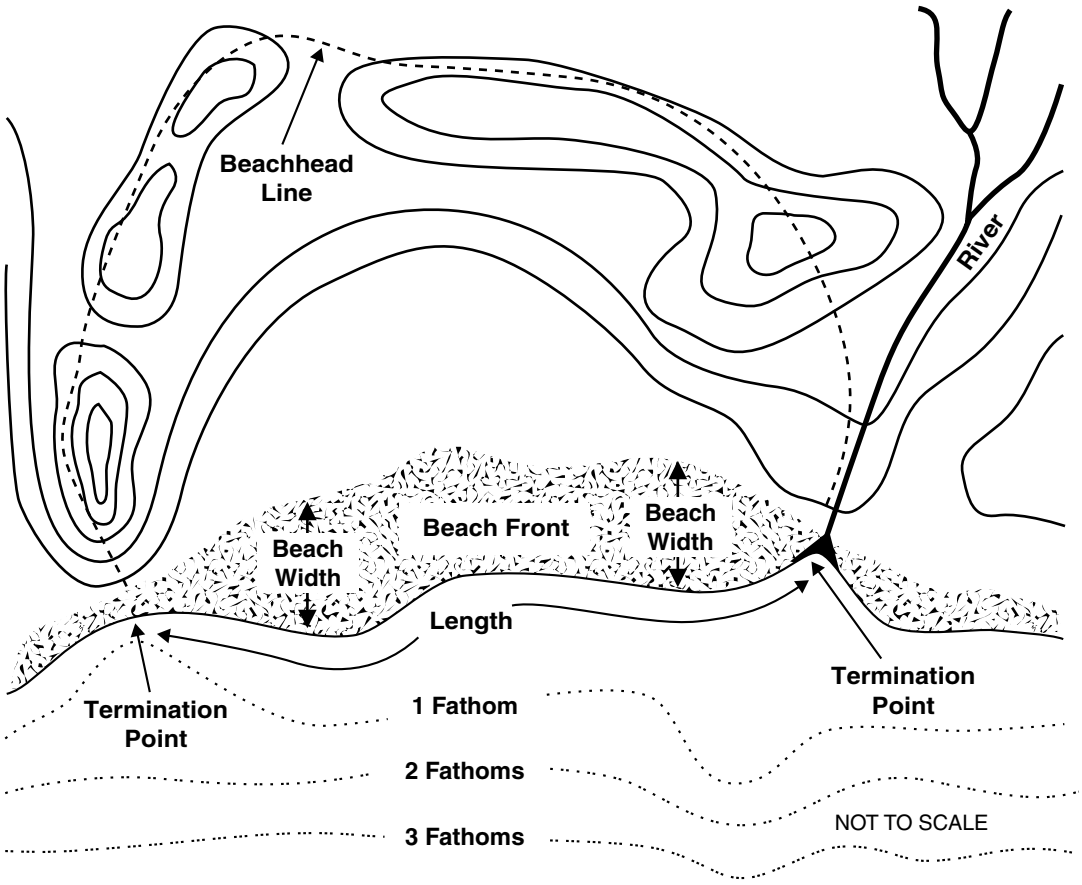

Figure G-12. Typical Beach Landing Area.

Surface and Obstacle Considerations

Normally, the surface condition of the combined foreshore and back shore areas is considered critical upon landing. The foreshore is generally white; the back shore begins where the beach discoloration changes from white to brownish gray and ends at the beginning of the hinterland by revealing a darker tone and taller vegetation on aerial photography.

Unfavorable or hazardous surface conditions include—

- Large rocks or reefs.
- Drop-offs (cliffs).
- Dense trees.
- Dense vegetation.

Obstacles include—

- Buildings.
- Military impediments (e.g., landing craft barriers, barbed wire).

BLS Accessibility

Because of the configuration of shorelines, usually the area most suitable for the execution of a landing operation is also the most easily organized for defense. The ideal beach for amphibious landing is one with—

- No obstructions in the sea approaches.
- Deep-water close inshore.
- Near shore gradients sufficiently deep for dry-ramp beaching of landing craft and ships.

- Soil composed of firm sand with gentle gradients or slopes.
- Small tides.
- No currents.
- No surfs.

The beach terrain should be—

- Gently rising, relatively clear, and with a firm surface that has adequate drainage.
- Flat or gently rising terrain, backed by a coastal range high enough to mask the landing area.

Ideal conditions are rarely found, so suitable areas must be evaluated to determine those that come nearest to optimum requirements. Other terrain considerations include:

- **Dunes.** Ground that is sharply broken by extensive dunes or a low coastal plateau provides the attacker with concealment from the defender's observation. The small compartments and corridors limit the range of defensive fire.
  - Transverse dunes are mounds of sand with their longest dimensions oriented at right angles to the prevailing wind. They usually have a steeper leeward slope than they have on the windward side.
  - Longitudinal dunes are sand formations whose longest dimensions are oriented in the same direction as the prevailing wind. They may have a symmetrical shape or may be without any particular shape at all. Longitudinal dunes may be over 100 miles in length. They are usually not backed by areas of standing water, such as swamps or marshes.
  - Because they are formed by windblown sand, coastal dunes are quite unstable landforms, appearing in one location as a transverse dune, only to disappear and reform as a longitudinal dune elsewhere. The winds responsible for their formation may also be the means for their destruction.
- **Mountains.** Mountains located directly on the sea usually limit the number of beaches large enough to accommodate a landing force of effective size. Where steep ground is lightly defended or neglected by the defender, a small force may seize it and gain surprise. Airborne or airmobile troops may be used to block the movement of defensive reserves to the landing area or to secure passes through the mountains and thus prevent the defender from interfering with the amphibious landing.
- **Sandbars.** These offshore sand formations are usually found near coastlines with a gentle beach gradient. During stormy weather the sandbars will be found further offshore than during calmer weather conditions. Sandbars paralleling the coast may cause a lagoon to form between themselves and the coastline; direct access to the shore is dependent on openings (channels) through the sandbar areas. The locations of these channels are highly variable, and current photography is required before the actual landing takes place. Soil analysis, beach materials, and other trafficability aspects are normally reported by terrain and soil analysts. However, IAs will determine beach exits (roads, airstrips, etc.).

Beach Landing Site Collection Checklist Preparation

A collection checklist must be prepared for each potential BLS using the following items:

- Identification. Local name and military designation.
- Location
  - Map reference—include series and sheet number(s) of both tactical and air/ground series.
  - Political unit, area, universal transverse mercator (UTM) coordinates, and geographic coordinates of the termination points.
  - Landmark reference—description and location of the landmark and azimuth and distance from landmark to termination point.
- Related water body or watercourses. Cross-reference to appropriate collection file.

- Length between termination points. Self-explanatory.
- Seashore form. Concave, convex, straight or irregular.
- Coastal terrain type. Emergent, submergent, compound, coral reef, delta, volcanic, fault, manmade, and so on.
- Alignment. High-water shoreline and low-water shoreline.
- Beach width at low water. Self-explanatory.
- Beach width at high water. Self-explanatory.
- Backshore
  - Slope.
  - Material (composition, texture, trafficability).
  - Obstacles.
  - Vegetation.
- Foreshore
  - Slope.
  - Material (composition, texture, and trafficability).
  - Obstacles.
  - Vegetation.
- Near shore. (Give alignment and distance from low water shoreline).
  - 10 m (5 fathoms) depth line at low water.
  - 6 m (3 fathoms) depth line at low water.
  - 4 m (2 fathoms) depth line at low water.
  - 2 m (1 fathom) depth line at low water.
  - Obstacles.
  - Reefs (near shore):
    - Type and location.
    - Distance from low water shoreline.
    - Length and width.
    - Slope (direction).
    - Depth to surface of reef at low tide.
    - Depth to surface of reef at high tide.
    - Height of surface above water at high and low tide.
    - Effects of surf.
    - Effects on tide.
    - Channel through reef (alignment, width, and depth at low water).
  - Reefs (offshore):
    - Type and location.
    - Distance from low water shoreline.
    - Length and width.
    - Slope (direction).
    - Depth to surface of reef at low tide.
    - Depth to surface of reef at high tide.
    - Height of surface above water at high and low tide.
    - Effects of surf.
    - Effects on tide.
    - Channel through reef (alignment, width, and depth at low water).
- Offshore Conditions
  - Water depth.
  - Offshore islands (location and characteristics).
  - Sandbars.
    - Location and distance from low water shoreline.
    - Length and width.
    - Consistency.
    - Slope (seaward and landward).
    - Passages (alignment, width, and depth).
    - Depth at high and low waters.
    - Obstacles (type, location, and characteristics).
- Beach features. Natural and manmade features such as cusps, runners, stream mouths, groins, piers, and outfall pipes, etc.
  - Type and location.
  - Number and extent.
  - Bypass possibilities.
  - Influence on operations.
- Tide
  - Type (diurnal, semi-diurnal, or mixed).
  - Type range (spring, topic, and diurnal).
  - Range.
  - Meteorological effects.
- Surf
  - Breakers (type, average height, distance formed from shore, f lines).
  - Period.
  - Width of surf zone.

  - Direction from which swells approach coast.
  - Weather and seasonal effects.
- Currents. Location, direction, and velocity.
- Beach exits.
  - Type and location.
  - Number and condition.
- Coastal terrain. Cross-reference to appropriate collection file.
  - Critical terrain features (location, type, bypasses, and influence on operations).
  - Obstacles (location, type, extent, bypasses, and influence on operations).
  - Cross-country movement (troops, wheeled vehicles, and tracked vehicles).
- Support area concealment and cover (location and type).
- Dispersal and storage area. Location and description.
- Availability of fresh water. Location and quantity.
- Defenses. Location and type.

Terrain overlays are normally prepared by the terrain analysis detachment and added to the checklist. Overlays include presentations depicting cross-country movement, vegetation, slope, soil drainage pattern, ridgelines, etc.

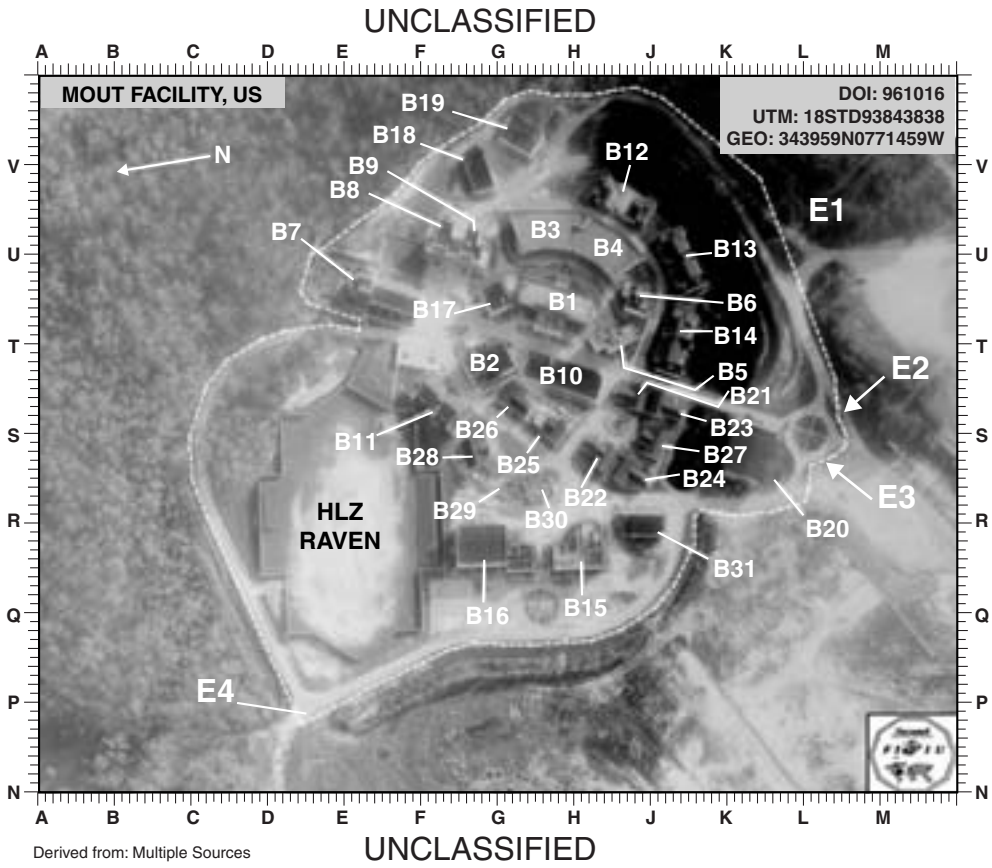
Beach Landing Site Overlays

IAs assist all-source intelligence and GEOINT analysts with preparing overlays of the proposed primary and alternate beach landing sites. Beach landing sites are referred to by their nickname. See MCWP 2-12.1 for information on preparation of overlays.

APPENDIX H. IMAGERY AND SUPPORTING INTELLIGENCE REPORTS

This appendix provides examples of MAGTF intelligence products derived from the fusion of available imagery and supporting IMINT and all-source intelligence reports. Such products support tactical planning and decisionmaking. The examples provided are:

- Image and supporting intelligence report for the MOUT facility, Camp LeJeune, NC.
- Image and supporting intelligence report for the Marine Corps Air Station, New River, NC.
- Image and supporting intelligence report for Helicopter Landing Zone Vulture, Camp LeJeune, NC.
- Image and supporting intelligence report for Onslow Beach North, Camp LeJeune, NC.
- Image and supporting intelligence report for Kin Red Beach, Okinawa, Japan.



MOUT FACILITY

Center Coordinates
UTM 18STD93843838
GEO 343959N0771459W

Map Reference
Sheet: Camp Lejeune MIM
Series: V742S
Edition: 1-DMA
Datum: NAD 83/WGS 84

Size
Length 1025 ft (312 m)
Width 800 ft (244 m)

Surface Material
Silty sand
Gravel

Remarks: The MOUT facility is located approximately 2 km ENE of OP-2. The primary use of the MOUT facility is combat training in an urban environment. The MOUT facility consists of 31 buildings of varying sizes and shapes. Roof types are a mixture of garbled and flat. The facility is surrounded by trees of varying heights. The exit from the MOUT facility is a loose surface road which provides access to Lyman road. Note: All building measurements are listed at length x width x height.

Exits

Anno. #	Type	True Bearing	Distance	Width	Surface Material
E1	Road, loose-surfaced	146	169.8 m (557 ft)	7.6 m (25 ft)	Earth and sand
E1	Road, loose-surfaced	175	163.1 m (535 ft)	6.4 m (21 ft)	Earth and sand
E1	Road, loose-surfaced	181	165.0 m (541 ft)	6.7 m (22 ft)	Earth and sand
E1	Road, loose-surfaced	281	204.3 m (670 ft)	5.6 m (18 ft)	Earth and sand

Remarks: E1 leads approximately 100 meters (328 feet) southeast to F-3 Range Road. E2 and E3 lead approximately 1.0 km (0.5 nm) to Lyman. E4 exits onto an unnamed road.

Buildings

B1—Three-story, T-shaped building (hotel), 120' x 58' x 37' (37 x 18 x 11 m) with near-flat roof. Helicopter landing point is painted with non-reflective white airfield markings and consists of a concrete slab roof. HLZ is 38' x 33' (12 x 10 m). OP building roof is outlined by a parapet with scuppers and a gutter. (Scupper is an opening in the wall of a building through which water can drain). The front portion of the roof is comprised of tube trusses or transverse monitors. Grappling and rappeling anchors are located throughout the roof.

B2—Two-story, square-shaped building (city hall), 72' x 60' x 31' (22 x 18 x 9 m) consisting of a near flat roof outlined by a parapet, however the NW corner is lower than the main roof. The roof has grappling and rappeling anchors throughout the roof. The corner of the roof is open to a crawl space.

B3, B4—Two-story, crescent-shaped buildings (apartment buildings) outer edge 121' x 60' x 31' (37 x 18 x 9 m) inner edge 84' x 60' x 31' (26 x 18 x 9 m) outlined by a parapet with scuppers. Grappling and rappeling anchors are located throughout the roof. The roofs are near flat with a ridge dissecting each building's roof, a near flat roof dissected by a ridge separates the two buildings.

B5—Three-story, basically rectangular-shaped building (office building) 72' x 36' x 38' (22 11 x 12 m). Grappling and rappeling anchors located on the SE and NW sides of roof. The southern end of the building is two stories, 23 ft (7 m) in height. An elevator shaft is located in the center of the roof.

B6—Two-story, "l"-shaped building (office building) 44' x 36' x 25' (13 x 11 x 8m). NW portion of the roof is a concrete slab.

B7—Rectangular "T"-shaped building with dormers (church building) 121' x 73' x 77' (37 x 22 x 23 m) with a gable roof made of asphalt and fiberglass shingles. Height of main building is 48 ft (15 m), steeple 29 ft (9 m).

B8—Three-story, irregular-shaped building (business/ residential building) 53' x 34' x 39' (16 x 10 x 12 m) with near flat roof. Grappling and rappeling anchors are located throughout the roof.

B9—Three-story, irregular-shaped building (business/ residential building) 50' x 47' x 39' (15 x 14 x 12 m) with near flat roof.

B10—Single-story, rectangular-shaped building (business/ residential building) 128' x 46' x 18' (39 x 14 x 5 m) with flat roof.

B11—Two-story, rectangular-shaped building (townhouse) 103' x 53' x 30' (31 x 16 x 9 m) has gable roof with dormer. Roof consists of fiberglass shingles reinforced by wood trusses.

B12—Two-story, rectangular-shaped building (townhouse) 103' x 53' x 30' (31 x 16 x 9 m), front and rear portions of building walls are incomplete. Gable-roofed dormer with fiberglass shingles and reinforced wooden trusses.

B13, B14—Two-story, rectangular-shaped buildings (townhouses) 103' x 53' x 30' (31 x 16 x 9 m) with gable roof and dormers. Roof consists of fiberglass shingles reinforced with wooden trusses.

B15—Two-story, irregular-shaped building (school) 88' x 73' x 25' (27 x 22 x 18 m) with near flat roof built up on A 2" slab of concrete. Rappeling anchors are located throughout the roof. Two fire escape ladders are located on the NE and SW sides of the roof.

B16—Two-story, irregular-shaped building (gymnasium) 128' x 74' x 25' (38 x 23 x 8 m) with a near flat roof, fire escape ladders located on the S side of the building.

B17—Two-story, square-shaped building (retail bank) 43' x 36' x 26' (13 x 11 x 8 m) with a near-flat roof. Grappling anchors located throughout the roof. Roof access by ladder is located on the NW corner of the building.

B18—Single-story, basically rectangular-shaped buildings with hipped roofs (service stations) 74' x 32' x 17' (23 x 10 x 5 m).

B19—Single-story, rectangular-shaped building (warehouse) 63' x 43' x 23' (19 x 13 x 7 m) with a near flat roof. Roof consists of standing seam metal on metal purlins. Purlins are horizontal timbers supporting the rafters of a roof.

B20—Single-story, square-shaped building (warehouse) 83' x 63' x 25' (25 x 19 x 8 m) with a near flat roof on metal purlins, with a mellaine (mellaine is a partial story between two main stories of a building). The MOUT CTF administration building is not a part of the MOUT training facility.

B21, B22—Single-story, "T"-shaped buildings with basements (residential buildings) 52' x 40' x 15' (16 x 12 x 5 m). Gable style roof is reinforced with wooden trusses. Chimney height extends 2 ft (.6 m) above the peak of the roof.

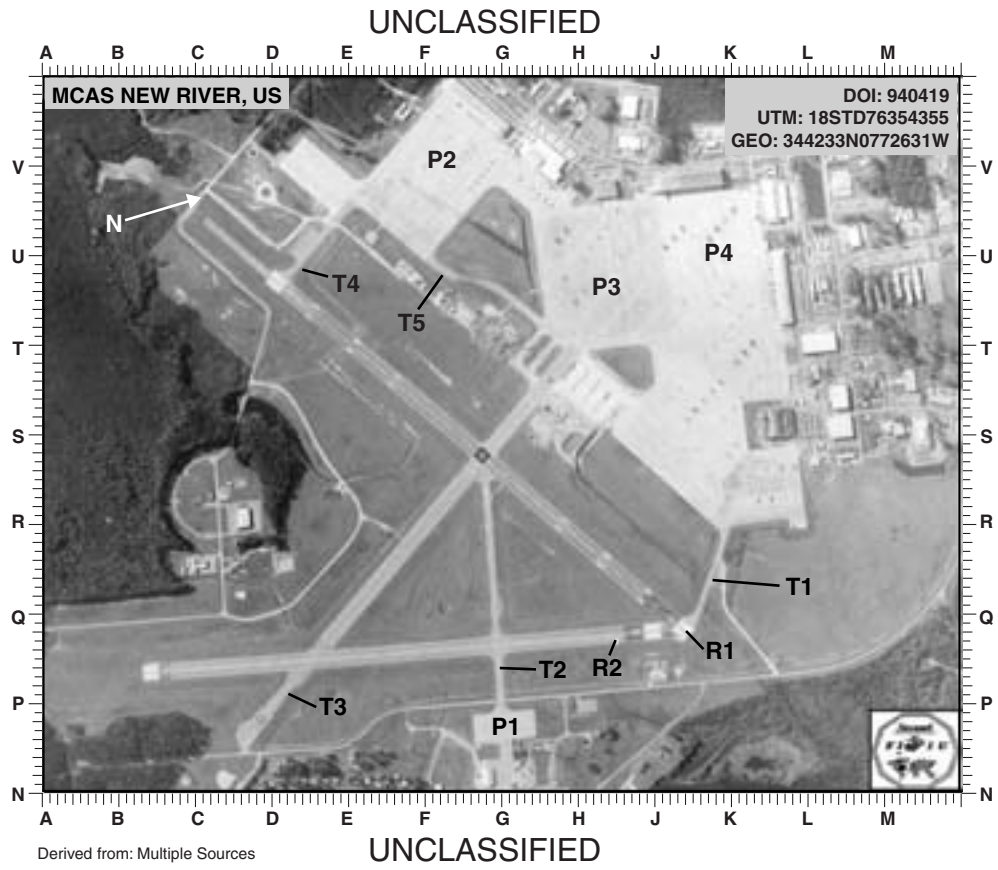
B23, B24, B26—Single-story, "T"-shaped buildings (residential buildings) 52' x 40' x 15' (16 x 12 x 5 m) with gable style roof reinforced with wood trusses. Chimney extends 2 ft (.6 m) above peak.

B25—Residential irregular-shaped building 52' x 40' x 15 (16 x 12 x 5 m) with a gable style roof reinforced with wood trusses.

B27, B28—Single-story, "T"-shaped buildings (residential buildings) 44' x 40' x 17' (13 x 12 x 5 m) with reinforced wooden trusses. Gable roofing consists of fiberglass shingles.

B29, B30—Small "T"-shaped buildings 44' x 40' x varies (13 x 12 x varies m). Nearly destroyed buildings may provide some shelter from direct fire.

B31—Single-story, rectangular-shaped buildings with hipped roofs (service stations) 74' x 32' x 17' (23 x 10 x 5 m).



MCAS NEW RIVER

Center Coordinates

Length
Total: 1,393.4 m (4,752 ft)
Usable: 1,373.1 m (4,505 ft)

Width
Average Backshore Width: 66.4 m (218 ft)
Visible Foreshore Width: 24.0 m (79 ft)

Surface Material

Nearshore: Sand and mud

Foreshore: Sand

Backshore: Sand

Trafficability

Personnel:	Wet—Fair Dry—Good
Wheeled:	Wet—Fair Dry—Good
Tracked:	Wet—Fair Dry—Good

Tides

Tidal type: Diurnal	Average beach gradient: 1:116	Matting recommended: Yes
Tidal range: 1.0 m (3 ft.)	Firmness: Firm when wet	

MFP capable:	JLOTS capable:	LCAC offload capable:
No; see remarks.	No; see remarks.	Yes; see remarks.

Location: Onslow Beach North is approximately 13.1 km (7.1 nm) south-southeast of the U.S. Embassy. It is 3.7 km (2.0 nm) east-northeast of HLZ BLUEBIRD and 1.4 km (0.8 nm) east-southeast of HLZ Albatross.

Characteristics remarks: Onslow Beach North is not MPF capable since there is no MPF capable port within 92.7 km (50 nm) of the beach. It is not JLOTS capable due to insufficient beach gradient. It is, however, LCAC off-load capable due to average backshore width of 66.4 m (218 ft). All coordinates provided in this report were derived from the 1:50,000 scale map sheet listed in the reference above. All measurements were derived by MEF imagery analysts from mensurated imagery.

Obstructions

Anno. #	Type	True Bearing	Distance	Length	Width
N1	Pier	225	542.0 m (1,778 ft)	20.3 m (67 ft)	4.5 m (15 ft)

Obstruction remarks: None

Exit remarks: Cross-country to partial cross-country exits are available along the entire beach. These exits are too numerous to list individually. Parallel to the beach is a road that extends 6.3 km (3.4 nm) southwest to New River Inlet and 1.4 km (0.8 nm) northeast to Onslow Beach Road which leads approximately 2.8 km (1.5 nm) north-northeast to Highway 172. There are several buildings and compounds in the hinterland along the road.

Tides

Tidal type: Mixed	Average beach gradient: 1:116	Matting recommended: Yes
Tidal range: 1.7 m (5.6 ft)	Firmness: Firm when wet	

Location and general remarks: Kin Red Beach is located 17.6 km northeast of Kadena Airfield. Four islands obstruct the mouth of Kin Bay. The beach is flanked by a RO/RO pier to the west and a breakwater to the east. There are intermittent streams that cross the beach that could hinder lateral movement during inundation.
Personnel exit via cross-country along the entire beach length. The beach is backed by a concrete stepped seawall (B4) that severely restricts tracked vehicle and prevents wheeled vehicle movement. The town of Kin Cho further hinders and channels movement from the beach. Hinterland consists of hills covered with dense vegetation of varying heights, cultivated fields, numerous urban developments and/or tombs.

Obstructions

Anno. #	Type	True Bearing	Distance	Length	Width
N1	Dolphin	226	157 m (515 ft)	3 m (10 ft)	3 m (10 ft)
N2	Coral	250	86 m (282 ft)	18 m (59 ft)	20 m (66 ft)

B3	Coral	077	51 m (167 ft)	16 m (52 ft)	13 m (43 ft)
B4	Coral	270 thru 070	Varies	270 m (886 ft)	9 m (30 ft)

Obstruction remarks: Obstructions are measured from the beach center to the obstruction.

Exit remarks: See location and general remarks above.

APPENDIX I. IMAGERY INTELLIGENCE TARGET FOLDERS

A target folder contains intelligence that provides location, the components of a target or target complex, indicates its vulnerability(ies), and its relative importance. It also contains related materials prepared for planning and executing actions against a specific target. A major prerequisite for starting a target folder is the relative degree of permanence of the potential target. In addition, local command SOPs will provide guidance as to targets needed to have folders maintained.

Imagery Analysis

IMINT is often the definitive information source of intelligence support to targeting. IMINT input is reliable, accurate, and current, and often forms the basis for targeting decisions. Imagery analysis is a vital component in the tactical and strategic targeting process. It is often the IA, during the analysis of imagery, who—

- Discovers potential targets and draws them to the attention of the command (CMD section).
- Conducts the target study that is an analysis of the proposed target from imagery and other pertinent sources.
- Takes the information provided by the target analysis and puts it into a target folder format.

Target Analysis

The intelligence support coordinator (ISC) is responsible to the AC/S G-2 for imagery intelligence efforts supporting the MEF's targeting process. Before a possible target can be selected for attack, it must be developed to the point where its composition, strengths, and vulnerabilities are well known.

- The analysis of a target requires the collection and evaluation of many items of information. The target folder is an instrument for the compilation and organization of relevant data produced by the target analysis. Decisions by the force fires coordinator and FSCs regarding whether to attack a proposed target and weapon system selection are critically influenced by the information in the target folder.
- Once a possible target has been identified and approved for inclusion in the target intelligence data base, the IA and all-source intelligence analysts will prepare a target folder. This analysis presents all available pertinent information on the proposed target from the following sources:
  - **Reference Materials.** Perform a thorough check of all available intelligence reference materials. Interrogation, CI, ground reconnaissance, and signals intelligence reports all may be useful.
  - **GEOINT.** Ensure current maps (latest editions) and other GEOINT are available of the target area.
  - **Mission Coverage.** Examine comparative coverage of the target area from past and ongoing imagery collections missions. If the latest available coverage is old, incomplete, poor quality or the installation is under construction or renovation, new collection missions may be required.

Specifications

A target folder is a unit-created and maintained reference file on permanent potential targets in the AO and AOI. It contains the results of the target study (analysis) and any updates or collateral intelligence. Target folders—

- May be used as a pre-mission briefing aid for aircrews to orient them on target location, recognition, defenses, and obstacles. IAs may use target folders strictly as a reference file on important

intelligence targets within the unit's AO. Such folders can be compiled to show an installation's development or an enemy unit's organization.

- Have common characteristics and contain a minimum of important elements.
- Are for permanent targets. A permanent C2 node, troop training area, warehouse area, port facility or fixed missile site are good potential targets for target folders. Temporary targets such as troops in the field, supply dumps, and ships in port or truck convoys are usually not proper subjects for target folders.
- Are current. Because the information within a target folder may be used for target planning, it must be kept current. The target folder must be updated to reflect changes in defenses, physical characteristics, unit reorganization, important equipment, and so on.
- Are concise. Target folders are compact; only intelligence and other information pertinent to the commander's PIRs or IRs are included.
- Are accurate. Intelligence and other information within a target folder must be accurate to allow realistic targeting plans to be made. Answers to intelligence requirements must be specific to provide maximum value. For example, explicitly describe enemy defenses, target dimensions, shape, construction, use, and capacities.

Note: Target folders should be reviewed periodically or with each new photograph mission (intelligence priorities, resources, and time permitting) and their contents checked against new information or intelligence requirements.

Format and Components

There is no standard format for a target folder. Instead, it is a product tailored to meet all supported commanders' intelligence requirements.

Although the contents of a target folder will vary according to unit SOP, most will at a minimum contain the following components:

- Target folder index.
- Target worksheet.
- Target information sheet.
- Target illustration sheet.

The following items can be used to supplement the target folder:

- Target history sheet (supplement to the target worksheet).
- Map extract (supplement to the target information sheet).
- Sketch map or photographic overlay (supplement to the target information sheet).
- Building dimensions (supplement to the target illustration sheet). See appendix H for appropriate formulas for computing dimensions on imagery.

Target Folder Index

The index is located on the outside cover or on the first page of the target folder. It displays the contents of the folder (see figure I-1).

TARGET FOLDER INDEX

(Target Name)

	Page
Target worksheet	1
Target history sheet	2
Target Information sheet	3
Map extract	4
Sketch map	5
Target illustration sheet	6
Building or facility dimensions	7

Figure I-1. Sample Target Folder Index.

Target Worksheet

The target worksheet (see figure I-2) is organized with seven subheadings:

TARGET WORKSHEET

TARGET NUMBER:	2345-A23456
TARGET DESCRIPTION:	Sulphur Springs Valley Electric Power Station
TARGET LEADS:	Location: 320423N1105035W Elevation: 4,200 Feet Accuracy: Horizontal = +/- 100 Meters Vertical = +/- 10 Meters Datum: WGS 84 Source: V798, Douglas, AZ, Ed 5, 4048-1, Jun 86, DMAAC
SOURCES OF INFORMATION:	MSN 06-2028, 16TRS, 22 Jun 89, Photos V001-V010; EPW, 31 May 89 (F-6)
DATE OF INFORMATION:	10 Jun 99
DATE CONFIRMED AND SOURCE:	22 Jun 99, Imagery
DISTRIBUTION:	G-3, Force Fires Center, 1st MARDIV, 3d MAW

Figure I-2. Sample Target Worksheet.

Target Number

This number indicates the number of targets evaluated. For example, if the target number is 086, then it is the 86th target that the section has processed.

Target Description

Enter the name of the target and/or type of target. The type of target could be an airport, oil refinery, electric company, munitions plant, chemical plant, bunker complex or base area. If you have more than one of the same types of targets in the same area, you will number them (e.g., Bamberg SAM Site No. 3).

Target Leads

LEADS stands for: location (geographic coordinates), elevation, accuracy (horizontal and vertical), datum, and source (imagery, maps, etc.).

- Enter the geographic coordinates of the target, expressed in degrees, minutes, seconds; North or South (N or S) and East or West (E or W), depending on the location in regard to the equator and the prime meridian. Coordinates will represent the center of mass of the target.
- Include the elevation.
- Include horizontal and vertical accuracy.
- Include the datum (basis for the accuracy of the coordinates) used to derive the target location.
- Include the source of the information.

Sources of Information

Enter all other sources of information and intelligence available on the target. If possible, a P&A cell evaluation of the information and intelligence would be included (e.g., A-2, F-6). The map reference must include: series, sheet name, edition, sheet number, date, and production agency.

Date of Information

The date of the information is recorded on the target worksheet.

Date Confirmed and Source

Enter the date the target was confirmed and how it was confirmed. When using imagery, the date of information becomes the date of confirmation.

Distribution

Include those units and other agencies that normally receive the intelligence. Additionally, include all those that have requested the intelligence.

Target Information Sheet

A target information sheet (see figure I-3 on page I-4) is a detailed target description and continuation of the target worksheet information.

TARGET INFORMATION SHEET

BE NO:	0501-D57010	TARGET NO:	023
DATE OF INFO:	24 Nov 89	MAP SERIES:	V798
DATE COMPILED:	(Completion or update)	MAP SHEET NO:	4048 I
PROD CMD & NO:	5IDM-02	GEO REF GRID:	320423N1105035W
ELEVATION (MSL):	4,200 ft	UTM REF GRID:	12SXL00450474

LOCATION: The Sulphur Springs Valley Electric Power Station is located 36 mi SW of WILCOX, AZ, and 15 mi SE of the Southern Pacific Railroad tracks.

PHYSICAL CHARACTERISTICS: The target is 1,773 ft x 1,420 ft, located west of the highway. The RP is the generator hall that is a 56 ft x 174 ft, probably reinforced, with the following components: Boiler house is 59 ft from the RP on a 320-degree MAG heading. Substation (Transformer Yard) is 260 ft from RP on a 145-degree MAG heading. Fixed-top non-pressure liquid storage tank is 462 ft from RP on a 304-degree MAG heading. Coal Crushing Tower is 462 ft from RP on a 255-degree MAG heading. American Deck Coolers are 304 ft from RP on a 019-degree MAG heading. Smokestack is 174 ft from RP on a 320-degree MAG heading.

SIGNIFICANCE: The destruction of this target would stop or reduce electrical power to enemy military units in the vicinity.

OBSTRUCTIONS: The following obstruction is located within the target complex: 173 ft high smokestack 174 ft from RP on a 320-degree MAG heading. There are no visible obstructions outside the complex.

WEAPON RECOMMENDATIONS:

1. MEAN POINT OF IMPACT:	
2. PRIMARY WEAPON:	FUZING:
3. ALTERNATE WEAPON:	FUZING:
4. ON TARGET TONNAGE:	LEVEL:
5. OVER TARGET TONNAGE:	LEVEL:

OTHER INFORMATION: There are no visible bunkers, SAM sites or other antiaircraft emplacements.

Figure I-3. Sample Target Information Sheet.

Heading

The heading includes the classification and sheet name (TARGET INFORMATION SHEET).

Main Portion

The main portion of the target information sheet contains the following:

- BASIC ENCYCLOPEDIA (BE) NO: This is a number assigned to a specific target by the DIA. If a permanent BE number does not exist, an interim BE number may be used in accordance with unit or JTF SOP. The interim BE number must consist of 10 characters. The first four characters are composed of the World Aeronautic Chart Number on which the target is located; the remaining 6 characters are a combination of digits and letters determined by the unit SOP. Once this interim BE number is used, it must be used in all subsequent reporting on the target until DIA assigns a permanent BE number.
- DATE OF INFO: Enter the date of the most recent aerial imagery available in the target folder.
- DATE COMPILED: Enter the date when the target information sheet is completed or updated.
- PRODUCING COMMAND & NUMBER: Enter the producing command abbreviation and number.
- ELEVATION (MSL): Enter the target's actual elevation above mean sea level (MSL). This is obtained from the map sheet and is the elevation read from the contour lines, using the contour interval. The elevation may have to be interpolated when the target falls between two contour lines.

- TARGET NO: Transcribe the target number from the target worksheet.
- MAP SERIES: This is obtained from the map the target is located on. Transcribe map series from target worksheet (see figure I-2).
- MAP SHEET NO: This is obtained from the map. Transcribe map sheet number from the target worksheet (see figure I-2).
- GEO REF GRID: This is obtained from the map. Transcribe GEO coordinates from the target worksheet (see figure I-2).
- UTM REF GRID: This is obtained from the map. Transcribe UTM coordinates from the target worksheet (see figure I-2).
- LOCATION: Enter the physical location. For example, the Sulphur Springs Valley Electric Power Station is 3.6 miles (mi) SW of Wilcox, AZ, and 15 mi SE of the Southern Pacific Railroad tracks.
- PHYSICAL CHARACTERISTICS:
  - This is a complete description of the target. Identify the critical item within the target complex. The critical item is defined as: A component of the entire complex without which the complex would stop operation for the longest period of time. This critical item then becomes the primary target (PT). Determine the construction of the PT. Calculate the dimensions of the reference point (RP) to the target complex. Provide answers to the following questions: Is it operational? How far and in what direction or magnetic (MAG) heading are the other components of the complex from this RP?
  - The RP must be readily identifiable by the aircrews. If the critical item or PT is not readily identifiable from the air, determine through a process of elimination that RP the aircrews could distinguish from the air (e.g., smokestack, isolated storage tank, water tower). From this RP indicate in what direction and distance the PT is located. Are there railroads and highways close to the complex and in which direction? How many lanes are in the highway and what is it numbered (Hwy 40)? Are there service roads entering the complex? From which direction? How many lanes? Is the complex serviced by a rail spur? If so, from which direction does it enter the complex?
  - If extremely detailed target intelligence analysis is required, a sketch map or appendix may be used for enhancement.
  - To calculate dimensions to the target complex, use the formula GD = PD x DPRF.

    Example: If PD is .008 ft and DPRF is 10,000, then GD = .008 ft x 10,000 = 80 ft.
  - MAG is determined by placing the cross of the coordinate scale over the RP and shooting an azimuth toward the target. Read the grid-azimuth and add or subtract the grid-magnetic (GM) angle as specified in the map sheet legend. The GM angle is positive when it is being added to the grid azimuth, negative when subtracted from the grid azimuth. The RP is the roasting and sintering building. The grid azimuth to the receiving and handling building in the copper smelter complex is 299 degrees. By subtracting the GM angle, the MAG heading is 296 degrees.
- SIGNIFICANCE: This is a statement as to the significance of the target.

  Example: "Destruction of this target will deny the enemy 100,000 barrels of POL."
- OBSTRUCTIONS: List all obstructions in or near the target area that would hamper low-flying aircraft. External obstructions include urban areas, radio and television towers, power line towers, bridges and/or mountain ranges in proximity to the target RP. Obstructions within the target complex include smokestacks, water towers, high-tension power lines or towers, conveyor systems, etc.

- WEAPON RECOMMENDATIONS: Enter the format sub-headers that FFC or FSCC personnel will complete in this section.
- OTHER INFORMATION: Enter data not covered by the other subheadings that could have a bearing on the target, such as defenses.

  Examples: There are no visible bunkers, SAM sites, or antiaircraft emplacements. The target is encircled by SAM sites with 10 bunkers 2,000 ft from the center of the complex.

Target Illustration Sheet

A target folder is incomplete without illustrations. This includes as a minimum of one up-to-date annotated vertical photograph of the target. All imagery must have an accurately positioned magnetic north arrow, and the vertical photograph should have the boundaries of the target area outlined conspicuously. Oblique imagery can be included in the folder because it will aid in identifying the target from the air. Radar and infrared signatures are also helpful.

Target History Sheet

The target history sheet is a supplement to the target worksheet. It will follow the target worksheet in numerical sequence (see figure I-4).

Top

The top of the target history sheet contains a heading composed of the target's BE number (or unit assigned identification number), target name, target data inventory (TDI) category (optional), country, GEO/UTM coordinates, and map reference.

Body

The body of the target history sheet contains a listing of all reconnaissance missions with reference to the target. The columns are for mission date, mission number, quality of the imagery, action taken because of information extracted from the imagery (for example, "none," "new sketch map," "new target description," "significant change," etc), and the name of the IA who completed the imagery analysis.

Map Extract

A map extract of the target area may be used to supplement the target information sheet.

Sketch Map or Photograph Overlay

Some unit SOPs may require that a sketch map or photographic overlay of the target be included in

TARGET HISTORY SHEET

BE NO: _____ TARGET NAME _____

TDI CATEGORY _____ COUNTRY _____

GEO/UTM COORDS _____/_____

MAP REFERENCE _____

COMPONENT _____

	DATE	MISSION NO.	QUALITY	ACTION	IA
1					
2					
3					
4					

Figure I-4. Sample Target History Sheet.

the folder as supplementary information. The sketch map is a graphic representation of the target showing sufficient detail to satisfy IRs. Usually the sketch map will illustrate critical buildings and structures, transportation facilities (including roads), obstacles, defenses, and security measures.

A photographic overlay or sketch must convey a picture of what is on the ground (target and components) with the numbers or letters used to identify the important components and areas. RP is to represent the primary target or a more prominent feature. A properly prepared overlay should resemble the one in figure I-5 on page I-8. The location of numbers and lines need to be identical to the illustration. Avoid having lines cross features and other lines on the overlay.

General Information

Sketch maps are drawn freehand and are not to scale. If the photograph or map is drawn to scale, the scale is indicated. A magnetic north arrow, title, annotation, legend, date, and sketcher's unit, rank, name, are needed for a complete map. The classification must be indicated at top and bottom of the sketch map in larger than normal lettering.

Annotations

The following are methods of annotating on an overlay or photograph:

- The banding method is used when the photographs are of a large enough scale to place the annotations on top of each item so the item can still be seen. In this method, you would start to number the item at the upper left and continue across the illustration in a band; then return to the left edge and repeat. If there is a primary installation, number it "1," whatever its location in the illustration. Number 2 will then be the first designation in the upper left.
- The most preferred method is annotating by priority (listing in sequence of target components' significance), which is accomplished for those targets selected for tactical planning and bombing.
- Another method is alphanumeric code. In this method targets are grouped together by function and given an alphabetic designator (i.e., headquarters = A). The individual elements within the group are given a numeric designator (i.e., division headquarters A1, brigade headquarters A2, A3, etc.) The designators are given in order of priority. So A is the most important group and 1 is the most important element within the group.
- The last method is as specified in unit SOP.

The following suggestions may prove helpful in preparing your overlay:

- Do NOT place numbers or letters on top of small items being identified.
- Do NOT draw the lines so they intersect other lines or pass over important items.
- Place magnetic north arrow away from other annotation lines and orient it toward the top of the illustration.

Building Dimensions

Building and facility dimensions may be added to the target illustration sheet as supplementary information (see figure I-6 on page I-9). It should show the title (e.g., building dimensions), installation name (e.g., Sulpher Springs Valley Electric Power Station), RP annotation, type building or facility (e.g., generator hall), and dimensions (e.g., in feet or meters).

APPENDIX J. NATIONAL IMAGERY TRANSMISSION FORMAT COMPRESSION

We use compression to decrease imagery file sizes to transmit usable images in as short a time as possible. Remember that the average image size used in the tactical intelligence community is around 4 megabytes (MB). Transmission time over a T1 line is 4 minutes, but over a regular telephone line at 9,600 bits per second (bps), the transmission time goes up to 55 minutes. If we compress the image by 50 percent, or a 2:1 compression ratio, it will take only one-half the time (see figure J-1). Note that the times are still excessive for our original 4 MB image until around the 25:1 compression point for the 2,400 and 9,600 rates.

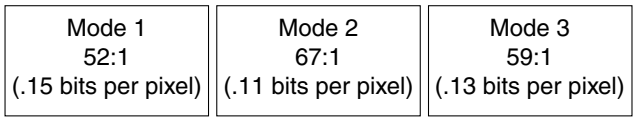

Figure J-1. Bi-Level Image Compression Results.

The first NITF algorithm that will be addressed is the Joint Photographic Experts Group (JPEG) image compression algorithm. The complete specifications are contained in MIL-STD-188-198A.

JPEG is one of the most popular and widely used compression algorithms. It is used on the World Wide Web and was adapted for use in the NITF in the early 1990s.

NITF JPEG also follows a model similar to those discussed previously to produce a compressed image. NITF JPEG's Forward Discrete Cosine Transform (FDCT) is just another mathematical formula. JPEG divides the image into 8 by 8-minimum coding units or neighborhoods, and then calculates the FDCT of each neighborhood. The quantizer rounds off or smooths the FDCT coefficients according to the table specifications, and then is encoded.

For decompression, JPEG recovers the quantized FDCT coefficients from the compressed data stream, takes the inverse transform (using embedded tables), and displays the image. This is a simple description; technical details are in the military standard. We need to know two things: How the various Q settings impact the quality of an image, and the time available to transmit the compressed image.

NITF JPEG provides several variants, Discrete Cosine Transform (DCT) lossy (8 and 12 bit), downsample JPEG, and lossless.

APPENDIX K. IMAGERY INTELLIGENCE
APPENDIX FORMAT

The IMINT operations appendix should explain how IMINT and relevant imagery-related elements under the OPCON or supporting the MAGTF will be used to support this plan. It should also provide guidance to subordinate commanders for the conduct of IMINT operations and the support of IMINT elements and personnel identified to fulfill the IMINT requirements.

APPENDIX 7 TO ANNEX B (INTELLIGENCE) TO MAGTF OPORD XXX (U)
Imagery Intelligence (U)

(U) REFERENCES: Identify DOD, NIMA, and other directives; combatant commander, JTF or other higher authorities' operations orders and tactics, techniques and procedures or SOP for intelligence and IMINT operations; pertinent maps and other geospatial information resources; and any other relevant references that pertain to anticipated IMINT operations.

1. (U) Situation

a. (U) Definition of the Area of Operations (AO) and Area of Interest (AOI). Describe the limits of the AO and AOI. Summarize pertinent weather, terrain and other AO's characteristics and conditions that may influence the conduct of IMINT operations.

b. (U) Enemy. Refer to Annex B and current intelligence estimates for threat capabilities, limitations, vulnerabilities, and OOB pertinent to IMINT operations.

c. (U) Assigned MAGTF Organic and Supporting IMINT Assets. Identify organic and supporting forces available to perform IMINT and imagery-related functions.

CLASSIFICATION

d. (U) Facts and Assumptions. Derived during the mission analysis step of the MCPP.

e. (U) IMINT Considerations. List key IMINT, intelligence or other considerations that impact this OPLAN or CONPLAN.

(1) (U) Availability of national source and commercial imagery.

(2) (U) IMINT support to and from JTF and other component headquarters.

(3) (U) Creation and manning of forward IMINT elements.

2. (U) Mission. State concisely the IMINT mission as it relates to the command's planned operation.

3. (U) Execution

a. (U) Concept of Operations. Reference the unit's intelligence SOP and Appendix 16 (Intelligence Operations Plan) to Annex B. Restate as appropriate the commander's intent and pertinent aspects of the unit's overall concept of operations as they relate to IMINT operations. Outline the purpose and concept of IMINT operations, specified priorities, and summarize the means and agencies to be employed in planning and directing, collecting, processing and exploiting, analyzing and producing, disseminating, and using IMINT during execution of the OPORD. Address the integration of JTF, other components, theater, national, and allied forces' IMINT operations.

b. (U) Tasks for IMINT and Related Units and Organizations, Subordinate Units, and Task Force Commanders/OICs.

(1) (U) Orders to Subordinate, Attached and Supporting Units. Use separate numbered subparagraphs to list detailed instructions for each unit conducting IMINT operations, including the originating headquarters, subordinate commands, and separate intelligence support units.

(a) (U) Major Subordinate Commanders

(b) (U) Commanding Officer, Intel Bn

1 Platoon Commander, Imagery Intelligence Platoon

2 OIC, JSTARS Common Ground Station Section

CLASSIFICATION

3 SNCOICs, Direct Support Teams

4 OIC, Support Cell

5 OIC, Surveillance and Reconnaissance Cell

6 OIC, Production and Analysis Cell

7 (Others as appropriate)

(c) (U) Commanding Officer, VMU Squadron

(d) (U) Commanding Officer, Force Reconnaissance Company

(2) (U) Requests to Higher, Adjacent, and Cooperating Units. Provide separate numbered subparagraphs pertaining to each unit not organic, attached or supporting and from which IMINT support is requested, including other components, JTF headquarters, allied or coalition forces, theater and national operational and intelligence elements.

c. (U) Coordinating Instructions. (Reference Appendix 16 (Intelligence Operations Plan), and command and other pertinent forces and organizations intelligence and CI SOPs. Detail here or in supporting tabs key changes to SOPs. Additional topics to include or emphasize here are requesting IMINT support; direct liaison among subordinate commanders, MAGTF IMINT units, staff officers, and pertinent external organizations and agencies; routine and time-sensitive reporting procedures and formats, etc.)

4. (U) Administration and Logistics

a. (U) Logistics. Reference Annex D (Logistics). Identify IMINT unique logistic requirements and concerns, such as: any unique combat service support requirements, procedures, and other guidance to support MAGTF IMINT units and operations; or procedures for specialized technical logistic support necessary from external organizations.

b. (U) Personnel. Identify intelligence unique IMINT personnel requirements and concerns.

5. (U) Command and Control

a. (U) Command Relationships. Reference Annex J (Command Relationships). Provide any instructions necessary regarding MAGTF command relationships that will influence unit IMINT operations.

CLASSIFICATION

b. (U) Information Management. Reference Annex U (Information Management), Annex C (Operations) and Appendix 16 (Intelligence Operations Plan). Provide any instructions necessary regarding information management (time-sensitive and routine reporting criteria, intelligence databases, reports, etc.) that will influence MAGTF IMINT operations.

c. (U) Communications and Information Systems. Reference Appendix 16 (Intelligence Operations Plan) and Annex K (Communications and Information Systems). Provide any instructions necessary regarding CIS that will influence MAGTF IMINT operations.

d. (U) Intelligence C2 Nodes and Facilities. Reference the unit's intelligence SOP and Appendix 16 (Intelligence Operations Plan). Provide guidance and instructions necessary regarding the establishment and operations of intelligence and IMINT C2 nodes and facilities (e.g., the surveillance and reconnaissance cell).

UNMANNED AERIAL VEHICLE PLAN

(U) REFERENCES: (As appropriate)

1. (U) Mission. Conduct real-time surveillance, target acquisition, and imagery intelligence throughout the MAGTF area of responsibility until termination of hostilities, per Annex B (Intelligence) and Annex C (Operations) to the MAGTF OPLAN.

2. (U) Execution. The UAV squadron will provide UAVs and C2 crews in support of MAGTF operations. The MAGTF G-2, in coordination with the G-3, will exercise operational control of all tactical surveillance UAVs within the AO unless otherwise directed. The ISC, under the staff cognizance of the AC/S G-2, plans, coordinates, and supervises MAGTF UAV intelligence missions.

3. (U) Tasks. Detachment,_____,_____UAV Squadron will—

a. (U) Prepare a UAV employment plan and overlay to depict the UAV's concept of employment supporting combat operations ashore and submit these to the MAGTF G-2 (Attn: ISC or CMDO).

b. (U) Assign surveillance UAV equipment, and personnel to provide real-time video/imagery intelligence in support of MAGTF operations as directed by Annex B (Intelligence) to the MAGTF OPLAN, daily ATOs, and other intelligence orders.

c. (U) Provide RRS detachments at designated locations afloat and ashore.

d. (U) Initiate action to obtain approved frequencies for UAV support, per Annex K (CIS) to the MAGTF OPLAN.

CLASSIFICATION

e. (U) Coordinate flight operations through appropriate air control agencies as assigned in Annex N (Aviation Operations) to the MAGTF OPLAN.

4. (U) MAGTF UAV Surveillance Sectors/Routes. To facilitate the assignment and coordination of tactical surveillance missions, UAV loiter areas and surveillance routes are designated in the enclosures to this tab.

CVBG . . . . . carrier battle group

DASC . . . . . direct air support center
DATEDES . . . . . date desired
DCI . . . . . Director of Central Intelligence
DCT . . . . . discrete consine transform
DE. . . . . dissemination element
DIA . . . . . Defense Intelligence Agency
DISN . . . . . defense information systems network
DMRF . . . . . denominator of the map representative factor
DMS . . . . . defense message system
DOD . . . . . Department of Defense
DODIPP . . . . . Department of Defense Intelligence Production Program
DPL. . . . . digital photo lab
DPRF . . . . . denominator of the photo representative factor
DRO . . . . . Departmental Requirements Officer
DS . . . . . downsample
DSA . . . . . directed search area
DSCS . . . . . defense satellite communications system
DSN . . . . . defense switched network
DSSCS . . . . . defense special security communications system
EO . . . . . electro-optical

E&R . . . . . evasion and recovery
EW . . . . . electronic warfare

5D . . . . . demand driven direct digital dissemination
FDCT . . . . . forward discrete consine transform
FLIR . . . . . forward-looking infrared
FSCC. . . . . fire support coordination center
FSSG. . . . . force service support group
FTI . . . . . fixed target indicator

GB. . . . . gigabytes
GCCS . . . . . global command and control system
GCE . . . . . ground combat element
GCS. . . . . ground control station
GD. . . . . ground distance
GDT . . . . . ground data terminal
GENSER. . . . . general service
GEOINT . . . . . geographic intelligence
GRG . . . . . gridded reference graphic
GSP . . . . . ground sensor platoon

HD. . . . . horizontal distance
HML/A . . . . . Marine light/attack helicopter squadron
HQMC . . . . . Headquarters Marine Corps
HUMINT . . . . . human intelligence

I&W . . . . . indications and warning
IA . . . . . imagery analyst
IAS . . . . . intelligence analysis system
ICR . . . . . intelligence collection requirement
IDR . . . . . intelligence dissemination requirement
IESS . . . . . imagery exploitation software system
IIP . . . . . imagery intelligence platoon
IMINT. . . . . imagery intelligence
INMARSAT . . . . . international maritime satellite system
intel bn . . . . . intelligence battalion
IOC . . . . . intelligence operations center
IPB . . . . . intelligence preparation of the battlespace
IPIR. . . . . initial photo interpretation report
IPL . . . . . imagery product library
IPR . . . . . intelligence production requirement
IR . . . . . intelligence requirement
ISC . . . . . intelligence support coordinator
JAC . . . . . joint analysis center
JDISS . . . . . joint deployable intelligence support system
JFACC . . . . . joint force air component commander
JFC . . . . . joint force commander
JFLCC. . . . . joint force land component commander
JFMCC . . . . . joint force maritime component commander
JIC. . . . . joint intelligence center
JISE. . . . . joint intelligence support element
JOPES . . . . . Joint Operation Planning and Execution System
JPEG . . . . . joint photographic experts group
JSIPS. . . . . Joint Services Imagery Processing System
JSTARS . . . . . joint surveillance, target attack radar system
JTAR/S . . . . . joint tactical air reconnaissance/surveillance
JTF . . . . . joint task force
JWICS. . . . . Joint Worldwide Intelligence Communications System

kbps. . . . . kilobytes per second
kw . . . . . kilowatt

LAN . . . . . local area network
LAR . . . . . light armored reconnaissance
LEADS . . . . . location, elevation, accuracy, datum, source
LF . . . . . landing force
LOC . . . . . lines of communications
LOS. . . . . line of sight
LP . . . . . landing point
LTIOV . . . . . latest time intelligence is of value

MACCS . . . . . Marine air command and control system
MACG . . . . . Marine air control group
MAG. . . . . Marine aircraft group
MAGTF . . . . . Marine air-ground task force
MASINT. . . . . measurement and signature intelligence
mbps . . . . . megabits per second

Manpack SIDS . . . . . man packable secondary imagery dissemination system
MARCORSYSCOM. . . . . Marine Corps Systems Command
MARFOR . . . . . .Marine Corps forces
MARFORRES . . . . . Marine Corps Forces Reserve
MAW . . . . . Marine aircraft wing
MB . . . . . megabyte
MCCDC . . . . . Marine Corps Combat Development Command
MCIA . . . . . Marine Corps Intelligence Activity
MD . . . . . .map distance
MEF . . . . . Marine expeditionary force
MEU(SOC) . . . . . Marine expeditionary unit (special operations capable)
MHG . . . . . MEF headquarters group
mi . . . . . .miles
MIPIR . . . . . .multimission imagery photo interpretation report
MOS . . . . . military occupational specialty
MSC . . . . . major subordinate command
MSI . . . . . .multispectral imagery
MSL . . . . . mean sea level
MTI . . . . . moving target indicator
MWSS. . . . . Marine wing support squadron

NAI . . . . . named area of interest
NDS . . . . . .NIMA delivery system
NIIRS . . . . . National Imagery Interpretability Rating Scale
NIMA . . . . . .National Imagery and Mapping Agency
NIPRNET . . . . . .Nonsecure Internet Protocol Router Network
NIST . . . . . .national intelligence support team
NITF . . . . . .national imagery transmission format
NRO . . . . . National Reconnaissance Office
NRT . . . . . .near-real-time
NSA . . . . . National Security Agency
NTIS . . . . . night thermal imaging system
NTS. . . . . night targeting system

OIC . . . . . .officer in charge
OOB . . . . . .order of battle
OPCON. . . . . .operational control

P&A . . . . . production and analysis
PCMCIA . . . . . Personal Computer Memory Card International Association
PCS . . . . . portable control station
PD . . . . . photo distance
PI. . . . . .photo interpreter
PIR . . . . . priority intelligence requirement
POL. . . . . .petroleum, oils, and lubricants
PT . . . . . .primary target

QRS. . . . . quick response system

R&S . . . . . reconnaissance and surveillance
RAOC . . . . . .rear area operations center
RATO . . . . . .rocket-assisted takeoff
RECCEXREP . . . . . .reconnaissance exploitation report
RFI . . . . . .request for intelligence
RMS . . . . . .requirements management system
ROC . . . . . .reconnaissance operations center
RP . . . . . .reference point
RRS. . . . . remote receive station
RS . . . . . .receive segment
RVT . . . . . remote video terminal

SACC . . . . . .supporting arms coordination center
SAFE. . . . . selected area for evasion
SAM . . . . . .surface-to-air missile
SAID . . . . . SAFE area intelligence description
SAR. . . . . synthetic aperture radar
SARC . . . . . .surveillance and reconnaissance cell
SATCOM . . . . . .satellite communications
SCDL . . . . . .surveillance and control data link
SCI . . . . . .sensitive compartmented information
SCR. . . . . .single channel radio
SERE. . . . . .survival, evasion, resistance, and escape
SGS . . . . . .squadron ground station
SHF . . . . . super high frequency
SI. . . . . .special intelligence
SIDS . . . . . .secondary imagery dissemination system
SIG . . . . . sensor interface group

SIGINT . . . . . signals intelligence
SIPRNET . . . . . SECRET Internet Protocol . . . . . Router Network
SL . . . . . slope
SOP . . . . . standing operating procedure
SR . . . . . short range
STOM . . . . . ship to objective maneuver
SVCR . . . . . super videocassette recorder

TACC . . . . . tactical air command center
TACPHOTO . . . . . tactical intelligence photographic capability
TARPS . . . . . tactical airborne reconnaissance pod system
TCU . . . . . tracking control unit
TDI . . . . . target data inventory
TDN . . . . . tactical data network
TEG. . . . . tactical exploitation group
TIGDL . . . . . tactical interoperable ground data link
T/O . . . . . table of organization
TOT. . . . . time over target
TRAP . . . . . tactical recovery of aircraft and personnel
TTP . . . . . tactics, techniques, and procedures
TUAV . . . . . tactical unmanned aerial vehicle

UAV . . . . . unmanned aerial vehicle
UHF . . . . . ultrahigh frequency

VCR . . . . . videocassette recorder
VD. . . . . vertical distance
VHS . . . . . very high speed
VMFA(AW) . . . . . Marine fighter/attack (all weather) squadron
VMU . . . . . Marine unmanned aerial vehicle squadron
VRN . . . . . vehicle registration number

WAN. . . . . wide area network
WG . . . . . workstation group
WICP . . . . wing initial communications package

SECTION II. DEFINITIONS

administrative control—Direction or exercise of authority over subordinate or other organizations in respect to administration and support, including organization of Service forces, control of resources and equipment, personnel management, unit logistics, individual and unit training, readiness, mobilization, demobilization, discipline, and other matters not included in the operational missions of the subordinate or other organizations. Also called ADCON. (JP 1-02)

air contingency MAGTF—An on-call, combat-ready MAGTF that deploys by airlift. Air contingency MAGTFs vary in size based on mission requirements and the availability of airlift. Because they deploy by air, they generally have a limited organic logistics capability, and require an arrival airfield. Air contingency MAGTFs usually are activated to respond to developing crises, and may deploy independently or in conjunction with other expeditionary forces. Also called ACM.

all-source intelligence—1. Intelligence products and/or organizations and activities that incorporate all sources of information, most frequently including human resources intelligence, imagery intelligence, measurement and signature intelligence, signals intelligence, and open-source data, in the production of finished intelligence. **2.** In intelligence collection, a phrase that indicates that in the satisfaction of intelligence requirements, all collection, processing, exploitation, and reporting systems and resources are identified for possible use and those most capable are tasked. (JP 1-02)

area of interest—That area of concern to the commander, including the area of influence, areas adjacent thereto, and extending into enemy territory to the objectives of current or planned operations. This area also includes areas occupied by enemy forces who could jeopardize the accomplishment of the mission. Also called AOI. (JP 1-02)

area of operations—An operational area defined by the joint force commander for land and naval forces. Areas of operation do not typically encompass the entire operational area of the joint force commander, but should be large enough for component commanders to accomplish their missions and protect their forces. Also called AO. (JP 1-02)

assessment—1. Analysis of the security, effectiveness, and potential of an existing or planned intelligence activity. **2**. Judgment of the motives, qualifications, and characteristics of present or prospective employees or "agents." (JP 1-02)

attach—1. The placement of units or personnel in an organization where such placement is relatively temporary. **2**. The detailing of individuals to specific functions where such functions are secondary or relatively temporary, e.g., attached for quarters and rations; attached for flying duty. (JP 1-02)

aviation combat element—The core element of a Marine air-ground task force (MAGTF) that is task-organized to conduct aviation operations. The aviation combat element (ACE) provides all or a portion of the six functions of Marine aviation necessary to accomplish the MAGTF's mission. These functions are antiair warfare, offensive air support, assault support, electronic warfare, air reconnaissance, and control of aircraft and missiles. The ACE is usually composed of an aviation unit headquarters and various other aviation units or their detachments. It can vary in size from a small aviation detachment of specifically required aircraft to one or more Marine aircraft wings. The ACE itself is not a formal command. Also called ACE. (JP 1-02)

basic intelligence—Fundamental intelligence concerning the general situation, resources, capabilities, and vulnerabilities of foreign countries or areas which may be used as reference material in the planning of operations at any level and in

evaluating subsequent information relating to the same subject. (JP 1-02)

battle damage assessment—The timely and accurate estimate of damage resulting from the application of military force, either lethal or nonlethal, against a predetermined objective. Battle damage assessment can be applied to the employment of all types of weapon systems (air, ground, naval, and special forces weapon systems) throughout the range of military operations. Battle damage assessment is primarily an intelligence responsibility with required inputs and coordination from the operators. Battle damage assessment is composed of physical damage assessment, functional damage assessment, and target system assessment. Also called BDA. (JP 1-02) In Marine Corps usage, the timely and accurate estimate of the damage resulting from the application of military force. BDA estimates physical damage to a particular target, functional damage to that target, and the capability of the entire target system to continue its operations. (MCRP 5-12C)

battlespace—The environment, factors, and conditions that must be understood to successfully apply combat power, protect the force, or complete the mission. This includes the air, land, sea, space, and the included enemy and friendly forces; facilities; weather; terrain; the electromagnetic spectrum; and the information environment within the operational areas and areas of interest. (JP 1-02)

battlespace dominance—The degree of control over the dimensions of the battlespace which enhances friendly freedom of action and denies enemy freedom of action. It permits force sustainment and application of power projection to accomplish the full range of potential operational and tactical missions. It includes all actions conducted against enemy capabilities to influence future operations. (MCRP 5-12C)

beach—1. The area extending from the shoreline inland to a marked change in physiographic form or material or to the line of permanent vegetation (coastline). **2.** In amphibious operations, that portion of the shoreline designated for landing of a tactical organization. (JP 1-02)

beachhead—A designated area on a hostile or potentially hostile shore that, when seized and held, ensures the continuous landing of troops and materiel, and provides maneuver space requisite for subsequent projected operations ashore. (JP 1-02)

beach landing site—A geographic location selected for across-the-beach infiltration, exfiltration or resupply operations. Also called BLS. (JP 1-02)

beach width—The horizontal dimensions of the beach measured at right angles to the shoreline from the line of extreme low water inland to the landward limit of the beach (the coastline). (JP 1-02)

centers of gravity—Those characteristics, capabilities, or sources of power from which a military force derives its freedom of action, physical strength, or will to fight. (JP 1-02)

centralized control—In military operations, a mode of battlespace management in which one echelon of command exercises total authority and direction of all aspects of one or more warfighting functions. It is a method of control where detailed orders are issued and total unity of action is the overriding consideration. (MCRP 5-12C)

collection (acquisition)—The obtaining of information in any manner, including direct observation, liaison with official agencies, or solicitation from official, unofficial, or public sources. (JP 1-02) In Marine Corps usage, the gathering of intelligence data and information to satisfy the identified requirements. (MCRP 5-12C)

collection agency—Any individual, organization or unit that has access to sources of information and the capability of collecting information from them. (JP 1-02)

collection management—In intelligence usage, the process of converting intelligence requirements into collection requirements, establishing priorities, tasking or coordinating with appropriate collection sources or agencies, monitoring results, and retasking, as required. (JP 1-02)

collection plan—A plan for collecting information from all available sources to meet intelligence requirements and for transforming those requirements into orders and requests to appropriate agencies. (JP 1-02)

collection requirement—An established intelligence need considered in the allocation of intelligence resources to fulfill the essential elements of information and other intelligence needs of a commander. (JP 1-02)

combatant command—A unified or specified command with a broad continuing mission under a single commander established and so designated by the President, through the Secretary of Defense and with the advice and assistance of the Chairman of the Joint Chiefs of Staff. Combatant commands typically have geographic or functional responsibilities. (JP 1-02)

combat data—Data derived from reporting by operational units. (MCRP 5-12C)

combat service support element—The core element of a Marine air-ground task force that is task-organized to provide the combat service support necessary to accomplish the Marine air-ground task force mission. The combat service support element varies in size from a small detachment to one or more force service support groups. It provides supply, maintenance, transportation, general engineering, health services, and a variety of other services to the Marine air-ground task force. It may also contain other Service or foreign military forces assigned or attached to the MAGTF. The combat service support element itself is not a formal command. Also called CSSE. (Approved for inclusion in next edition of MCRP 5-12C)

combat surveillance—A continuous, all-weather, day-and-night, systematic watch over the battle area in order to provide timely information for tactical combat operations. (JP 1-02)

command and control—The exercise of authority and direction by a properly designated commander over assigned and attached forces in the accomplishment of the mission. Command and control functions are performed through an arrangement of personnel, equipment, communications, facilities, and procedures employed by a commander in planning, directing, coordinating, and controlling forces and operations in the accomplishment of the mission. Also called C2. (JP 1-02) Also in Marine Corps usage, the means by which a commander recognizes what needs to be done and sees to it that appropriate actions are taken. (MCRP 5-12C)

command element—The core element of a Marine air-ground task force that is the headquarters. The command element is composed of the commander, general or executive and special staff sections, headquarters section, and requisite communications support, intelligence and reconnaissance forces, necessary to accomplish the MAGTF's mission. The command element provides command and control, intelligence, and other support essential for effective planning and execution of operations by the other elements of the MAGTF. The command element varies in size and composition. Also called CE. (JP 1-02)

commander's critical information requirements—A comprehensive list of information requirements identified by the commander as being critical in facilitating timely information management and the decisionmaking process that affect successful mission accomplishment. The two key subcomponents are critical friendly force information and priority intelligence requirements. (JP 1-02) Information regarding the enemy and friendly activities and the environment identified by the commander as critical to maintaining situational awareness, planning future activities, and facilitating timely decisionmaking. Also called CCIR.

NOTE: CCIRs are normally divided into three primary subcategories: priority intelligence requirements; friendly force information requirements; and essential elements of friendly information. (MCRP 5-12C)

commander's intent—A commander's clear, concise articulation of the purpose(s) behind one or more tasks assigned to a subordinate. It is one of two parts of every mission statement which guides the exercise of initiative in the absence of instructions. (MCRP 5-12C)

contingency—An emergency involving military forces caused by natural disasters, terrorists, subversives, or by required military operations. Due to the uncertainty of the situation, contingencies require plans, rapid response, and special procedures to ensure the safety and readiness of personnel, installations, and equipment. (JP 1-02)

control—1. Authority which may be less than full command exercised by a commander over part of the activities of subordinate or other organizations. **2.** In mapping, charting, and photogrammetry, a collective term for a system of marks or objects on the earth or on a map or a photograph, whose positions or elevations or both, have been or will be determined. **3.** Physical or psychological pressures exerted with the intent to assure that an agent or group will respond as directed. **4.** An indicator governing the distribution and use of documents, information, or material. Such indicators are the subject of intelligence community agreement and are specifically defined in appropriate regulations. (JP 1-02)

coordinating authority—A commander or individual assigned responsibility for coordinating specific functions or activities involving forces of two or more Military Departments or two or more forces of the same Service. The commander or individual has the authority to require consultation between the agencies involved, but does not have the authority to compel agreement. In the event that essential agreement cannot be obtained, the matter shall be referred to the appointing authority. Coordinating authority is a consultation relationship, not an authority through which command may be exercised. Coordinating authority is more applicable to planning and similar activities than to operations. (JP 1-02)

coordination—The action necessary to ensure adequately integrated relationships between separate organizations located in the same area. Coordination may include such matters as fire support, emergency defense measures, area intelligence, and other situations in which coordination is considered necessary. (MCRP 5-12C)

counterintelligence—1. Information gathered and activities conducted to protect against espionage, other intelligence activities, sabotage or assassinations conducted by or on behalf of foreign governments or elements thereof, foreign organizations or foreign persons or international terrorist activities. Also called CI. See also counterespionage; security. (JP 1-02) **2.** Within the Marine Corps, counterintelligence (CI) constitutes active and passive measures intended to deny a threat force valuable information about the friendly situation, to detect and neutralize hostile intelligence collection, and to deceive the enemy as to friendly capabilities and intentions. (MCRP 5-12C)

countermeasures—That form of military science that, by the employment of devices and/or techniques, has as its objective the impairment of the operational effectiveness of enemy activity. (JP 1-02)

critical vulnerability—An aspect of a center of gravity that if exploited will do the most significant damage to an adversary's ability to resist. A vulnerability cannot be critical unless it undermines a key strength. Also called CV. (MCRP 5-12C)

current intelligence—One of two categories of descriptive intelligence that is concerned with describing the existing situation. (JP 1-02)

damage assessment—1. The determination of the effect of attacks on targets. **2.** A determination of

the effect of a compromise of classified information on national security. (JP 1-02)

decentralized control—In military operations, a mode of battlespace management in which a command echelon may delegate some or all authority and direction for warfighting functions to subordinates. It requires careful and clear articulation of mission, intent, and main effort to unify efforts of subordinate leaders. (MCRP 5-12C)

descriptive intelligence—Class of intelligence which describes existing and previously existing conditions with the intent to promote situational awareness. Descriptive intelligence has two components: basic intelligence, which is general background knowledge about established and relatively constant conditions; and current intelligence, which is concerned with describing the existing situation. (MCRP 5-12C)

detachment—1. A part of a unit separated from its main organization for duty elsewhere. **2.** A temporary military or naval unit formed from other units or parts of units. (JP 1-02)

dissemination—Conveyance of intelligence to users in a suitable form. (JP 1-02)

dissemination management—Involves establishing dissemination priorities, selection of dissemination means, and monitoring the flow of intelligence throughout the command. The objective of dissemination management is to deliver the required intelligence to the appropriate user in proper form at the right time while ensuring that individual consumers and the dissemination system are not overloaded attempting to move unneeded or irrelevant information. Dissemination management also provides for use of security controls which do not impede the timely delivery or subsequent use of intelligence while protecting intelligence sources and methods. (MCRP 5-12C)

drop zone—A specific area upon which airborne troops, equipment or supplies are airdropped. (JP 1-02)

essential elements of friendly information—Key questions likely to be asked by adversary officials and intelligence systems about specific friendly intentions, capabilities, and activities so they can obtain answers critical to their operational effectiveness. Also called EEFI. (JP 1-02) Specific facts about friendly intentions, capabilities, and activities needed by adversaries to plan and execute effective operations against our forces. (MCRP 5-12C)

estimative intelligence—Class of intelligence which attempts to anticipate future possibilities and probabilities based on an analysis of descriptive intelligence in the context of planned friendly and assessed enemy operations. (MCRP 5-12C)

evasion and escape intelligence—Processed information prepared to assist personnel to escape if captured by the enemy or to evade capture if lost in enemy-dominated territory. (JP 1-02)

executive agent—A term used in DOD and Service regulations to indicate a delegation of authority by a superior to a subordinate to act on behalf of the superior. An agreement between equals does not create an executive agent. For example, a Service cannot become a DOD Executive Agent for a particular matter with simply the agreement of the other Services; such authority must be delegated by the Secretary of Defense. Designation as executive agent, in and of itself, confers no authority. The exact nature and scope of the authority delegated must be stated in the document designating the executive agent. An executive agent may be limited to providing only administration and support or coordinating common functions or it may be delegated authority, direction, and control over specified resources for specified purposes. (JP1-02)

force protection—Actions taken to prevent or mitigate hostile actions against Department of Defense personnel (to include family members), resources, facilities, and critical information. These actions conserve the force's fighting potential so it can be applied at the decisive time and place and incorporate the coordinated and synchronized offensive and defensive measures to

enable the effective employment of the joint force while degrading opportunities for the enemy. Force protection does not include actions to defeat the enemy or protect against accidents, weather, or disease. (JP 1-02)

friendly force information requirements—Information the commander needs about friendly forces in order to develop plans and make effective decisions. Depending upon the circumstances, information on unit location, composition, readiness, personnel status, and logistics status could become a friendly force information requirement. Also called FFIR. (MCRP 5-12C)

fusion—In intelligence usage, the process of examining all sources of intelligence and information to derive a complete assessment of activity. (JP 1-02)

global sourcing—A process of force provision or augmentation whereby resources may be drawn from any location/command worldwide. (MCRP 5-12C)

ground combat element—The core element of a Marine air-ground task force that is task-organized to conduct ground operations. It is usually constructed around an infantry organization but can vary in size from a small ground unit of any type, to one or more Marine divisions that can be independently maneuvered under the direction of the MAGTF commander. The ground combat element itself is not a formal command. Also called GCE. (JP 1-02)

helicopter landing zone—A specified ground area for landing assault helicopters to embark or disembark troops and/or cargo. A landing zone may contain one or more landing sites. (JP 1-02)

high-payoff target—A target whose loss to the enemy will significantly contribute to the success of the friendly course of action. High-payoff targets are those high-value targets, identified through wargaming, which must be acquired and successfully attacked for the success of the friendly commander's mission. Also called HPT. (JP 1-02)

high-value target—A target the enemy commander requires for the successful completion of the mission. The loss of high-value targets would be expected to seriously degrade important enemy functions throughout the friendly commander's area of interest. Also called HVT. (JP 1-02)

human intelligence—A category of intelligence derived from information collected and provided by human resources. Also called HUMINT. (JP 1-02) In Marine Corps usage, HUMINT operations cover a wide range of activities encompassing reconnaissance patrols, aircrew reports and debriefs, debriefing of refugees, interrogations of prisoners of war, and the conduct of CI force protection source operations. (MCRP 5-12C)

imagery—Collectively, the representations of objects reproduced electronically or by optical means on film, electronic display devices or other media. (JP 1-02)

imagery exploitation—The cycle of processing and printing imagery to the positive or negative state, assembly into imagery packs, identification, interpretation, mensuration, information extraction, the preparation of reports, and the dissemination of information. (JP 1-02)

imagery intelligence—Intelligence derived from the exploitation of collection by visual photography, infrared sensors, lasers, electro-optics, and radar sensors such as synthetic aperture radar wherein images of objects are reproduced optically or electronically on film, electronic display devices or other media. Also called IMINT. (JP 1-02)

imagery interpretation—1. The process of location, recognition, identification, and description of objects, activities, and terrain represented on imagery. (NATO) **2.** The extraction of information from photographs or other recorded images. Also called interpretation. (JP 1-02)

indications and warning—Those intelligence activities intended to detect and report time-sensitive intelligence information on foreign developments that could involve a threat to the United States or allied and/or coalition military, political,

or economic interests or to U.S. citizens abroad. It includes forewarning of enemy actions or intentions; the imminence of hostilities; insurgency; nuclear or non-nuclear attack on the United States, its overseas forces, or allied and/or coalition nations; hostile reactions to United States reconnaissance activities; terrorists' attacks; and other similar events. Also called I&W. (JP 1-02)

indications (intelligence)—Information in various degrees of evaluation, all of which bears on the intention of a potential enemy to adopt or reject a course of action. (JP 1-02)

indicator—In intelligence usage, an item of information which reflects the intention or capability of a potential enemy to adopt or reject a course of action. (JP 1-02)

information—1. Facts, data, or instructions in any medium or form. **2.** The meaning that a human assigns to data by means of the known conventions used in their representation. (JP 1-02)

information exchange requirement—The requirement for information to be passed between and among forces, organizations, or administrative structures concerning ongoing activities. Information exchange requirements identify who exchanges what information with whom, as well as why the information is necessary and how that information will be used. The quality (i.e., frequency, timeliness, security) and quantity (i.e., volume, speed, and type of information such as data, voice, and video) are attributes of the information exchange included in the information exchange requirement. Also called IER. (MCRP 5-12C)

infrared imagery—That imagery produced as a result of sensing electromagnetic radiations emitted or reflected from a given target surface in the infrared position of the electromagnetic spectrum (approximately 0.72 to 1,000 microns). (JP 1-02)

integration—1. A stage in the intelligence cycle in which a pattern is formed through the selection and combination of evaluated information. **2.** In photography, a process by which the average radar picture seen on several scans of the time base may be obtained on a print or the process by which several photographic images are combined into a single image. (JP 1-02)

intelligence—1. The product resulting from the collection, processing, integration, analysis, evaluation, and interpretation of available information concerning foreign countries or areas. **2.** Information and knowledge about an adversary obtained through observation, investigation, analysis, or understanding. (JP 1-02) Also in Marine Corps usage, intelligence is knowledge about the enemy or the surrounding environment needed to support decisionmaking. This knowledge is the result of the collection, processing, exploitation, evaluation, integration, analysis, and interpretation of available information about the battlespace and threat. (MCRP 5-12C)

intelligence data—Data derived from assets primarily dedicated to intelligence collection such as imagery systems, electronic intercept equipment, human intelligence sources, etc. (MCRP 5-12C)

intelligence discipline—A well defined area of intelligence collection, processing, exploitation, and reporting using a specific category of technical or human resources. There are seven major disciplines: human intelligence, imagery intelligence, measurement and signature intelligence, signals intelligence (communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence), open-source intelligence, technical intelligence, and counterintelligence. (JP 1-02)

intelligence estimate—The appraisal, expressed in writing or orally, of available intelligence relating to a specific situation or condition with a view to determining the courses of action open to the enemy or potential enemy and the order of probability of their adoption. (JP 1-02)

intelligence preparation of the battlespace—An analytical methodology employed to reduce uncertainties concerning the enemy, environment, and terrain for all types of operations. Intelligence preparation of the battlespace builds an extensive

database for each potential area in which a unit may be required to operate. The database is then analyzed in detail to determine the impact of the enemy, environment, and terrain on operations and presents it in graphic form. Intelligence preparation of the battlespace is a continuing process. Also called IPB. (JP 1-02) In Marine Corps usage, the systematic, continuous process of analyzing the threat and environment in a specific geographic area. (MCRP 5-12C)

intelligence-related activities—Those activities outside the consolidated defense intelligence program that: respond to operational commanders' tasking for time-sensitive information on foreign entities; respond to national intelligence community tasking of systems whose primary mission is support to operating forces; train personnel for intelligence duties; provide an intelligence reserve; or are devoted to research and development of intelligence or related capabilities. (Specifically excluded are programs that are so closely integrated with a weapon system that their primary function is to provide immediate-use targeting data.) (JP 1-02)

intelligence report—A specific report of information, usually on a single item, made at any level of command in tactical operations and disseminated as rapidly as possible in keeping with the timeliness of the information. Also called INTREP. (JP 1-02)

intelligence reporting—The preparation and conveyance of information by any means. More commonly, the term is restricted to reports as they are prepared by the collector and as they are transmitted by the collector to the latter's headquarters and by this component of the intelligence structure to one or more intelligence-producing components. Thus, even in this limited sense, reporting embraces both collection and dissemination. The term is applied to normal and specialist intelligence reports. (JP 1-02)

intelligence requirement—Any subject, general or specific, upon which there is a need for the collection of information, or the production of intelligence. Also called IR. (JP 1-02) In Marine Corps usage, questions about the enemy and the environment, the answers to which a commander requires to make sound decisions. (MCRP 5-12C)

interpretation—A part of the analysis and production phase in the intelligence cycle in which the significance of information is judged in relation to the current body of knowledge. See also intelligence cycle. (JP 1-02)

joint force—A general term applied to a force composed of significant elements, assigned or attached, of two or more Military Departments, operating under a single joint force commander. (JP 1-02)

joint force commander—A general term applied to a combatant commander, subunified commander or joint task force commander authorized to exercise combatant command (command authority) or operational control over a joint force. Also called JFC. (JP 1-02)

joint intelligence—Intelligence produced by elements of more than one Service of the same nation. (JP 1-02)

joint intelligence center—The intelligence center of the combatant command headquarters. The joint intelligence center is responsible for providing and producing the intelligence required to support the combatant commander and staff, components, subordinate joint forces and elements, and the national intelligence community. Also called JIC. (JP 1-02)

Joint Worldwide Intelligence Communications System—The sensitive compartmented information portion of the Defense Information Systems Network. It incorporates advanced networking technologies that permit point-to-point or multipoint information exchange involving voice, text, graphics, data, and video teleconferencing. Also called JWICS. (JP 1-02)

landing area—1. That part of the operational area within which are conducted the landing operations of an amphibious force. It includes the

beach, the approaches to the beach, the transport areas, the fire support areas, the airspace occupied by close supporting aircraft, and the land included in the advance inland to the initial objective. **2.** (Airborne) The general area used for landing troops and materiel either by airdrop or air landing. This area includes one or more drop zones or landing strips. **3.** Any specially prepared or selected surface of land, water, or deck designated or used for takeoff and landing of aircraft. (JP 1-02)

landing beach—That portion of a shoreline usually required for the landing of a battalion landing team. However, it may also be that portion of a shoreline constituting a tactical locality (such as the shore of a bay) over which a force larger or smaller than a battalion landing team may be landed. (JP 1-02)

liaison—That contact or intercommunication maintained between elements of military forces or other agencies to ensure mutual understanding and unity of purpose and action. (JP 1-02)

main effort—The designated subordinate unit whose mission at a given point in time is most critical to overall mission success. It is usually weighted with the preponderance of combat power and is directed against a center of gravity through a critical vulnerability. (MCRP 5-12C)

maintenance levels—The categories of maintenance and corresponding echelons of maintenance are organizational (first and second echelons), intermediate (third and fourth echelons), and depot (fifth echelon). (MCO 4790.2C)

maneuver warfare—A warfighting philosophy that seeks to shatter the enemy's cohesion through a variety of rapid, focused, and unexpected actions which create a turbulent and rapidly deteriorating situation with which the enemy cannot cope. (MCRP 5-12C)

Marine air-ground task force—The Marine Corps principal organization for all missions across the range of military operations, composed of forces task-organized under a single commander capable of responding rapidly to a contingency anywhere in the world. The types of forces in the Marine air-ground task force (MAGTF) are functionally grouped into four core elements: a command element, an aviation combat element, a ground combat element, and a combat service support element. The four core elements are categories of forces, not formal commands. The basic structure of the Marine air-ground task force never varies, though the number, size, and type of Marine Corps units comprising each of its four elements will always be mission dependent. The flexibility of the organizational structure allows for one or more subordinate MAGTFs, to be assigned. Also called MAGTF. (JP 1-02)

Marine Corps Planning Process—A six-step methodology which helps organize the thought processes of the commander and staff throughout the planning and execution of military operations. It focuses on the threat and is based on the Marine Corps philosophy of maneuver warfare. It capitalizes on the principle of unity of command and supports the establishment and maintenance of tempo. The six steps consist of mission analysis, course of action development, course of action analysis, comparison/decision, orders development, and transition. Also called MCPP. NOTE: Tenets of the MCPP include top down planning, single battle concept, and integrated planning. (MCRP 5-12C)

Marine expeditionary force—The largest Marine air-ground task force (MAGTF) and the Marine Corps principal warfighting organization, particularly for larger crises or contingencies. It is task- organized around a permanent command element and normally contains one or more Marine divisions, Marine aircraft wings, and Marine force service support groups. The Marine expeditionary force is capable of missions across the range of military operations, including amphibious assault and sustained operations ashore in any environment. It can operate from a sea base, a land base or both. Also called MEF. (JP 1-02)

Marine expeditionary unit—A Marine air-ground task force (MAGTF) that is constructed around an infantry battalion reinforced, a helicopter squadron reinforced, and a task-organized combat service support element. It normally fulfills Marine Corps forward sea-based deployment requirements. The Marine expeditionary unit provides an immediate reaction capability for crisis response and is capable of limited combat operations. Also called MEU. (JP 1-02)

Marine expeditionary unit (special operations capable)—The Marine Corps standard, forward-deployed, sea-based expeditionary organization. The MEU(SOC) is a Marine expeditionary unit, augmented with selected personnel and equipment, that is trained and equipped with an enhanced capability to conduct amphibious operations and a variety of specialized missions, of limited scope and duration. These capabilities include specialized demolition, clandestine reconnaissance and surveillance, raids, in-extremis hostage recovery, and enabling operations for follow-on forces. The MEU(SOC) is not a special operations force but, when directed by the National Command Authorities, the combatant commander, and/or other operational commander, may conduct limited special operations in extremis, when other forces are inappropriate or unavailable. It may also contain other Service or foreign military forces assigned or attached to the Marine air-ground task force. Also called MEU (SOC). (JP 1-02)

measurement and signature intelligence—Scientific and technical intelligence obtained by quantitative and qualitative analysis of data (metric, angle, spatial, wavelength, time dependence, modulation, plasma, and hydromagnetic) derived from specific technical sensors for the purpose of identifying any distinctive features associated with the target, source, emitter, or sender measurement of the same. The detected feature may be either reflected or emitted. (JP 1-02)

multispectral imagery—The image of an object obtained simultaneously in a number of discrete spectral bands. (JP 1-02)

National Imagery Transmission Format Standard (NITFS)—The standard for formatting digital imagery and imagery-related products and exchanging them among members of the Intelligence Community as defined by the Executive Order 12333, the DOD, and other departments and agencies of the United States Government, as governed by Memoranda of Agreement (MOA) with those departments and agencies. (MIL-STD-2500A)

national intelligence—Integrated departmental intelligence that covers the broad aspects of national policy and national security, is of concern to more than one department or agency, and transcends the exclusive competence of a single department or agency. (JP 1-02)

near real time—Pertaining to the timeliness of data or information which has been delayed by the time required for electronic communication and automatic data processing. This implies that there are no significant delays. (JP 1-02)

open source intelligence—Information of potential intelligence value that is available to the general public. Also called OSINT. (JP 1-02)

operational control—Transferable command authority that may be exercised by commanders at any echelon at or below the level of combatant command. Operational control is inherent in combatant command (command authority). Operational control may be delegated and is the authority to perform those functions of command over subordinate forces involving organizing and employing commands and forces, assigning tasks, designating objectives, and giving authoritative direction necessary to accomplish the mission. Operational control includes authoritative direction over all aspects of military operations and joint training necessary to accomplish missions assigned to the command. Operational control should be exercised through the commanders of subordinate organizations. Normally this authority

is exercised through subordinate joint force commanders and Service and/or functional component commanders. Operational control normally provides full authority to organize commands and forces and to employ those forces as the commander in operational control considers necessary to accomplish assigned missions. Operational control does not, in and of itself, include authoritative direction for logistics or matters of administration, discipline, internal organization or unit training. Also called OPCON. (JP 1-02)

order of battle—The identification, strength, command structure, and disposition of the personnel, units, and equipment of any military force. Also called OOB. (JP 1-02)

photogrammetry—The science or art of obtaining reliable measurements from photographic images. (JP 1-02)

priority intelligence requirements—Those intelligence requirements for which a commander has an anticipated and stated priority in his task of planning and decisionmaking. Also called PIR. (JP 1-02) In Marine Corps usage, an intelligence requirement associated with a decision that will critically affect the overall success of the command's mission. (MCRP 5-12C)

production management—Encompasses determining the scope, content, and format of each intelligence product, developing a plan and schedule for the development of each product, assigning priorities among the various production requirements, allocating processing, exploitation, and production resources, and integrating production efforts with intelligence collection and dissemination. (MCRP 5-12C)

radar imagery—Imagery produced by recording radar waves reflected from a given target surface. (JP 1-02)

reach back—The ability to exploit resources, capabilities, expertise, etc. not physically located in the theater or a joint operations area, when established. (MCRP 5-12C)

rear area—For any particular command, the area extending forward from its rear boundary to the rear of the area assigned to the next lower level of command. This area is provided primarily for the performance of support functions. (JP 1-02)

rules of engagement—Directives issued by competent military authority which delineate the circumstances and limitations under which United States forces will initiate and/or continue combat engagement with other forces encountered. Also called ROE. (JP 1-02)

safe area—A designated area in hostile territory that offers the evader or escapee a reasonable chance of avoiding capture and of surviving until he can be evacuated. (JP 1-02)

sanitize—To revise a report or other document in such a fashion as to prevent identification of sources, or of the actual persons and places with which it is concerned, or of the means by which it was acquired. Usually involves deletion or substitution of names and other key details. (JP 1-02)

sensitive compartmented information—All information and materials bearing special community controls indicating restricted handling within present and future community intelligence collection programs and their end products for which community systems of compartmentation have been or will be formally established. (These controls are over and above the provisions of DOD 5200.1-R, Information Security Program Regulation.) Also called SCI. (JP 1-02)

sensor data—Data derived from sensors whose primary mission is surveillance or target acquisition, such as air surveillance radars, counterbattery radars, and remote ground sensors. (MCRP 5-12C)

signals intelligence—1. A category of intelligence comprising either individually or in combination all communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence, however transmitted. **2.** Intelligence derived from communications,

electronics, and foreign instrumentation signals. Also called SIGINT. (JP 1-02)

situational awareness—Knowledge and understanding of the current situation which promotes timely, relevant, and accurate assessment of friendly, enemy, and other operations within the battlespace in order to facilitate decisionmaking. An informational perspective and skill that foster an ability to determine quickly the context and relevance of events that are unfolding. Also called SA. (MCRP 5-12C)

source—1. A person, thing, or activity from which information is obtained. **2.** In clandestine activities, a person (agent), normally a foreign national, in the employ of an intelligence activity for intelligence purposes. **3.** In interrogation activities, any person who furnishes information, either with or without the knowledge that the information is being used for intelligence purposes. In this context, a controlled source is in the employment or under the control of the intelligence activity and knows that the information is to be used for intelligence purposes. An uncontrolled source is a voluntary contributor of information and may or may not know that the information is to be used for intelligence purposes. (JP 1-02)

special operations—Operations conducted by specially organized, trained, and equipped military and paramilitary forces to achieve military, political, economic or informational objectives by unconventional military means in hostile, denied or politically sensitive areas. These operations are conducted across the full range of military operations, independently or in coordination with operations of conventional, non-special operations forces. Political-military considerations frequently shape special operations, requiring clandestine, covert, or low visibility techniques and oversight at the national level. Special operations differ from conventional operations in degree of physical and political risk, operational techniques, mode of employment, independence from friendly support, and dependence on detailed operational intelligence and indigenous assets. Also called SO. (JP 1-02)

special purpose Marine air-ground task force—A Marine air-ground task force organized, trained and equipped with narrowly focused capabilities. It is designed to accomplish a specific mission, often of limited scope and duration. It may be any size, but normally it is a relatively small force-the size of a Marine expeditionary unit or smaller. It may contain other Service or foreign military forces assigned or attached to the Marine air-ground task force. Also called SPMAGTF. (JP 1-02)

split base—Two or more portions of the same force conducting or supporting operations from separate physical locations. (MCRP 5-12C)

surveillance—The systematic observation of aerospace, surface or subsurface areas, places, persons, or things, by visual, aural, electronic, photographic or other means. (JP 1-02)

sustained operations ashore—The employment of Marine Corps forces on land for an extended duration. It can occur with or without sustainment from the sea. Also called SOA. (MCRP 5-12C)

synthetic aperture radar—A radar in which a synthetically long apparent or effective aperture is constructed by integrating multiple returns from the same ground cell, taking advantage of the Doppler effect to produce a phase history film or tape that may be optically or digitally processed to reproduce an image. (MIL-HDBK-850)

tactical intelligence—Intelligence that is required for planning and conducting tactical operations. (JP 1-02) In Marine Corps usage, tactical intelligence is concerned primarily with the location, capabilities, and possible intentions of enemy units on the battlefield and with the tactical aspects of terrain and weather within the battlespace. (MCRP 5-12C)

tactical warning—1. A warning after initiation of a threatening or hostile act based on an evaluation of information from all available sources.

2. In satellite and missile surveillance, a notification to operational command centers that a specific threat event is occurring. The component elements that describe threat events are: Country of origin-country or countries initiating hostilities. Event type and size-identification of the type of event and determination of the size or number of weapons. Country under attack-determined by observing trajectory of an object and predicting its impact point. Event time-time the hostile event occurred. Also called integrated tactical warning. (JP 1-02)

target—1. A geographical area, complex or installation planned for capture or destruction by military forces. **2.** In intelligence usage, a country, area, installation, agency or person against which intelligence operations are directed. **3.** An area designated and numbered for future firing. **4.** In gunfire support usage, an impact burst which hits the target. (JP 1-02)

target intelligence—Intelligence which portrays and locates the components of a target or target complex and indicates its vulnerability and relative importance. (JP 1-02)

technical control—The performance of specialized or professional service or the exercise of professional guidance or direction through the establishment of policies and procedures. (Proposed USMC definition for next revision of MCRP 5-12C.)

terrain intelligence—Intelligence on the military significance of natural and manmade characteristics of an area. (JP 1-02)

unconventional warfare—A broad spectrum of military and paramilitary operations, normally of long duration, predominantly conducted by indigenous or surrogate forces who are organized, trained, equipped, supported, and directed in varying degrees by an external source. It includes guerrilla warfare and other direct offensive, low visibility, covert or clandestine operations, as well as the indirect activities of subversion, sabotage, intelligence activities, and evasion and escape. Also called UW. (JP 1-02)

validation—A process normally associated with the collection of intelligence that provides official status to an identified requirement and confirms that the requirement is appropriate for a given collector and has not been previously satisfied. (JP 1-02)

warfighting functions—The six mutually supporting military activities integrated in the conduct of all military operations are:

1. command and control—The means by which a commander recognizes what needs to be done and sees to it that appropriate actions are taken.

2. maneuver—The movement of forces for the purpose of gaining an advantage over the enemy.

3. fires—Those means used to delay, disrupt, degrade or destroy enemy capabilities, forces or facilities as well as affect the enemy's will to fight.

4. intelligence—Knowledge about the enemy or the surrounding environment needed to support decisionmaking.

5. logistics—All activities required to move and sustain military forces.

6. force protection—Actions or efforts used to safeguard own centers of gravity while protecting, concealing, reducing or eliminating friendly critical vulnerabilities.

Also called WF. (MCRP 5-12C)

FOREWORD

Marine Corps Doctrinal Publication 2, *Intelligence*, and Marine Corps Warfighting Publication (MCWP) 2-1, *Intelligence Operations*, describe the doctrine and higher order tactics, techniques, and procedures employed in intelligence operations. Marine Corps Warfighting Publication 2-21, *Imagery Intelligence*, complements these publications by detailing the specific doctrine and tactics, techniques, and procedures for producing and collecting imagery intelligence (IMINT) in support of Marine Corps operational requirements.

The primary target audience of this publication is intelligence personnel responsible for the planning and execution of IMINT operations. Personnel who provide support to intelligence requirements through imagery operations, or personnel who utilize imagery intelligence, will also benefit from studying this publication.

Marine Corps Warfighting Publication 2-21 describes all aspects of IMINT, including basic doctrine, command and control relationships, communications and information systems, planning and execution, equipment, security, and training. It provides the fundamental information Marines need to understand, plan, and execute IMINT operations in support of the operating forces.

This publication supersedes MCWP 2-21, *Imagery Intelligence*, dated 6 September 2002, (formerly MCWP 2-15.4, modified to current short title by erratum dated 13 July 2004).

Reviewed and approved this date.

BY DIRECTION OF THE COMMANDANT OF THE MARINE CORPS

ROBERT S. WALSH
Lieutenant General, U.S. Marine Corps
Deputy Commandant for Combat Development and Integration

CHAPTER 1
FUNDAMENTALS

INTRODUCTION TO GEOSPATIAL INTELLIGENCE

Geospatial intelligence (GEOINT) was originally formed by integrating imagery, imagery intelligence (IMINT), and geospatial information. The meteorological and oceanographic (METOC) capability was added to the discipline in 2006. Advances in technology, along with the development of geospatial data standards, have created an environment in which the elements of GEOINT can be combined with one another as well as with other information sources. This fusion of resources has provided the means for conducting complex analysis and creating new specialized products.

Elements of Geospatial Intelligence

Geospatial intelligence is composed of four elements: imagery, IMINT, geospatial information, and METOC information.

Imagery. Imagery is a likeness or presentation of any natural or manmade feature or related object or activity and the positional data acquired at the same time the likeness or representation was acquired, including products produced by space-based national intelligence reconnaissance systems and likenesses or presentations produced by satellites, airborne platforms, unmanned aircraft systems (UASs), or other similar means.

Imagery Intelligence. Imagery intelligence is derived from the exploitation of collected images—by visual photography, infrared sensors, lasers, electro-optics, and radar sensors such as synthetic aperture radar (SAR)—wherein the images are reproduced optically or electronically on film, electronic display devices, or other media.

Geospatial Information. Geospatial information identifies the geographic location and characteristics of natural or constructed features and boundaries on the Earth. Geospatial information includes statistical data and information derived from remote sensing, mapping, and surveying technologies as well as mapping, charting, geodetic data and related products.

Meteorological and Oceanographic. Collectors of METOC information assess and characterize the current and future conditions, phenomena, and associated effects influencing the operational area's physical environment and integrate these time-sensitive essential elements of information (EEIs) into the continuous Marine Corps Planning Process (MCPP) to mitigate adverse conditions/exploit conditions of opportunity.

Components of Geospatial Intelligence

The components of GEOINT are the GEOINT discipline, GEOINT data, and GEOINT products and services.

The Geospatial Intelligence Discipline. Geospatial intelligence encompasses all of the activities related to the planning, collection, processing, analysis, exploitation, and dissemination of spatial information in order to gain intelligence about the national security or operational environment, depict this knowledge visually, and fuse the acquired knowledge with other information through analysis and visualization processes.

Geospatial Intelligence Data. Geospatial data refers to any data used to create GEOINT products. This data can be derived from either a single source or from multiple classified or unclassified sources. Analysts within the GEOINT discipline also incorporate data from other intelligence disciplines, such as human intelligence (HUMINT) or signals intelligence (SIGINT), to create fused all-source intelligence products.

Geospatial Intelligence Products and Services. Geospatial intelligence products range from standard geospatial data-derived products to specialized products that incorporate data from multiple sensors.

Standard Products. These data-derived products (i.e., maps, charts, imagery and digital information to support visualization activities such as a common operational picture [COP]) may be used alone or with multiple layers of data (e.g., vegetation, culture, languages, and weather) and intelligence information. Standard products are derived primarily from electro-optical (EO) sensors and existing geospatial data.

Specialized Products. Each specialized product is tailored for a particular purpose. The products may be developed using advanced technology to integrate multiple types of geospatial data as well as data from other intelligence sources; they may even incorporate the fourth dimension—time. These features enable analysts to create more comprehensive GEOINT products (e.g., two-color multiview, change detection, multi/hyper-spectral, line-of-sight products; environmental intelligence products; and fly-through studies).

Geospatial Intelligence Services. Geospatial intelligence services include all of the tools that enable users to access and manipulate data, such as the following:

- Geodetic surveys.
- Software development.
- Products and services tailored to support weapon systems.
- Calculation of precise locations for targeting of precision munitions.
- Training.
- On-site technical support.

MARINE CORPS GEOSPATIAL INTELLIGENCE ENTERPRISE

The Marine Corps GEOINT Enterprise is the geospatial component of the Marine Corps Intelligence, Surveillance, and Reconnaissance-Enterprise (MCISR-E) providing geospatial information and services (GI&S) to meet Marine Corps requirements.

Mission

The Marine Corps GEOINT Enterprise provides timely, relevant, and accurate GEOINT for planning, decisionmaking, and action in support of Marine Corps, joint, and combined operations.

Purpose

The Marine Corps GEOINT Enterprise integrates GEOINT systems, sensors, processes, and organizations into the distributed common ground/surface system-Marine Corps (DCGS-MC) and the larger MCISR-E architecture in order to provide a horizontally and vertically integrated GEOINT Enterprise that is capable of supporting all Marine Corps operational objectives.

Method

The Marine Corps adheres to established data standards to facilitate data sharing across the enterprise. This compliance enables end users to manipulate existing data for their particular mission requirements rather than recollecting data from previously serviced targets.

IMAGERY VERSUS IMAGERY INTELLIGENCE

Imagery and IMINT are not the same thing. Imagery is a likeness or representation containing embedded positional data; it has not yet been analyzed or evaluated against other intelligence. Imagery intelligence, on the other hand, is the function performed by the G-2/S-2 that involves imagery analysis and integration with other intelligence-related activities to produce all-source intelligence products. Imagery interpretation personnel conduct planning and perform tasking, collection, processing, exploitation, and dissemination (TCPED) of intelligence to the commander. Properly trained personnel, adequate time, and sophisticated equipment are needed to produce and provide IMINT. Raw imagery may be disseminated to tactical commanders in support of operations; however, caution must be exercised to ensure those commanders are aware of the potential for misleading information when intelligence is based on a single, unevaluated source. Imagery intelligence aids commanders and planners in the following two ways:

- It provides situational awareness of the natural, manmade, and cultural terrain in support of the intelligence preparation of the battlespace (IPB).
- It is a source for confirming the analysis produced by other intelligence disciplines.

OBJECTIVES OF IMAGERY INTELLIGENCE

The objectives of imagery intelligence are to increase the situational awareness of the commander and provide counterintelligence and force protection support. Imagery intelligence supports the commander's decisionmaking process by reducing uncertainty about the situation and the surrounding environment. It supports the identification of hostile intelligence collection operations, aids with the identification of Marine air-ground task force (MAGTF) vulnerabilities that could be exploited by the enemy, and assists with the evaluation of friendly security measures to counter these vulnerabilities.

CAPABILITIES AND LIMITATIONS OF IMAGERY INTELLIGENCE

Imagery intelligence has discipline-specific capabilities and limitations.

Capabilities

Imagery intelligence provides detailed and precise information regarding the location and the physical characteristics of the threat and the environment in which it is operating. It is the primary source of information concerning key terrain features, installations, and infrastructure used to build detailed intelligence studies, reports, and target materials. Order of battle (OOB) analysis, enemy course of action (COA) assessments, target intelligence development, and battle damage assessment (BDA) are intelligence functions that rely heavily upon IMINT.

Limitations

The two types of limitations for imagery intelligence are general limitations and sensor limitations.

General Limitations. The general limitations to IMINT are tied to the availability of resources, such as collection platforms, exploitation systems, high capacity communications, skilled personnel, and the time available to complete the TCPED cycle. The intelligence shortfalls associated with these general limitations are compounded by weather effects; enemy air defense capabilities; and enemy camouflage, concealment, and deception (CCD) activities.

Sensor Limitations. See appendix A for information on sensor limitations. It describes the basic capabilities and limitations of EO, radar, and infrared imagery sensors.

RESPONSIBILITIES AND PRODUCTS

The Marine Corps relies on a combination of national, theater, and organic IMINT sources to support both intelligence planning and intelligence operations. The employment of organic MAGTF intelligence collection assets within the assigned area of operations (AO) is not feasible until just prior to the introduction of forces due to the nature of expeditionary operations.

Consequently, national and/or theater intelligence assets should be exploited for IMINT support prior to entering the AO.

The MAGTF leverages external support during the planning and deployment phases of any operation. Even when employed, the MAGTF will continue to require national and theater support in specific areas to add depth and breadth to the reconnaissance effort and cover gaps in organic collection capabilities.

Marine Corps Imagery Intelligence Responsibilities

Imagery intelligence responsibilities differ depending on the type and echelon of the unit.

MAGTF G-2/S-2. The MAGTF assistant chief of staff (AC/S) for intelligence (G-2/S-2) has staff responsibility for intelligence, surveillance, and reconnaissance (ISR)—including support of IMINT operations. In conjunction with the AC/S for operations (G-3/S-3), the G-2/S-2 develops the intelligence operations plan (appendix 16 to annex B), the supporting IMINT plan (appendix 7 to annex B), and the reconnaissance and surveillance plan (appendix 14 to annex B), which allocate resources and assign specific imagery reconnaissance and supporting missions to the MAGTF and supporting elements. Factors affecting the development of intelligence and supporting IMINT plans are as follows:

- Priority intelligence requirements (PIRs).
- Commander's critical information requirements (CCIRs).
- Communications connectivity and information systems.
- Time available.
- Available information and intelligence from other sources.
- Redundancy.
- Assets available.
- Enemy situation.
- Enemy counterreconnaissance capabilities.

The MAGTF G-2/S-2 develops specific intelligence, reconnaissance, and imagery-related tasks based on the commander's intent, anticipated enemy activity, the MAGTF concept of operations (CONOPS), and the overall intelligence operations plan. Individual units are assigned reconnaissance tasks per the intelligence plan. The intelligence support coordinator (ISC), under the staff cognizance of the MAGTF G-2/S-2, establishes an intelligence operations center (IOC).

The Intelligence Operations Center. The IOC is established by the MAGTF G-2/S-2 to perform intelligence requirements management; staff cognizance of ongoing organic and supporting collection operations; and intelligence production, analysis, and dissemination. Key elements of the IOC follow:

- *Support cell*. The support cell is the primary element for conducting Marine expeditionary force (MEF)-wide intelligence requirements management, METOC support, collections and dissemination planning and direction, and intelligence staff cognizance of MEF organic and supporting intelligence and reconnaissance operations.

- *Surveillance and reconnaissance center*. The surveillance and reconnaissance center (SARC) is the primary element that supervises the execution of organic and supporting intelligence and reconnaissance plans.
- *Production and analysis cell*. The primary production and analysis (P&A) element of the MAGTF is the P&A cell. It processes and produces all-source intelligence products in response to requirements of the MAGTF. Additionally, it is the principal IMINT/GEOINT production element of the MEF.

Imagery Intelligence Units in the MAGTF. The MAGTF subordinate units conduct intelligence and reconnaissance planning and operations in support of their own efforts through a variety of means. Close coordination with the ISC and IOC is essential to ensure overall effective MAGTF intelligence operations and intelligence support to all commanders.

Imagery intelligence and imagery-related data and information are collected by a variety of assets, each with unique capabilities and limitations. The following MAGTF units and organizations are likely to be tasked with imagery-related collection missions and production support:

- Intelligence battalions.
- Marine aircraft wings (MAWs): Marine unmanned aerial vehicle squadrons (VMUs), Marine fighter/attack (all weather) squadrons (VMFA[AW]s).
- Force/division reconnaissance units.

Types of Imagery Intelligence Products

Imagery intelligence products include reports, mosaics, overlays, annotated images, and fused intelligence products. For a detailed discussion of imagery and IMINT products, see chapter 5. Appendix B provides examples of imagery products, while appendix C provides details on developing these products.

ROLE AND FUNCTIONS

Imagery intelligence provides MAGTF commanders operational and tactical intelligence support. Imagery and IMINT support the following intelligence functions:

- Support to the commander's estimate.
- Situation development.
- Indications and warning (I&W).
- Force protection.
- Targeting.
- Combat assessment.

TACTICAL IMAGERY INTELLIGENCE PRINCIPLES

The principles of tactical imagery intelligence are a focus on tactical intelligence; centralized management; G-2/S-2 facilitation; and a tailored, timely intelligence support.

Focus on Tactical Intelligence

National and theater imagery assets support operations by all echelons of the MAGTF. The MAGTF IMINT operations combine the generation of tactical intelligence and utilization of strategic/operational IMINT for tactical purposes. Consideration should always be given to TCPED of products in support of MAGTF operations.

While the management of IMINT collection and production is centralized in the MAGTF command element, the overall focus is to support the planning and executing of missions by every element involved in the operation. Critical products are disseminated to tactical commanders, who will be able to request additional IMINT support as required.

Centralized Management

Centralized collection and production management is essential due to the scarcity of IMINT assets, the broad dispersion of supported units, the limitations of range and capability, and the need to focus IMINT resources on the commander's PIRs. This centralizing of effort will be accomplished in the MAGTF IOC under the direction of the intelligence battalion commander functioning as the ISC. The MAGTF commander may attach or place task-organized IMINT elements in direct support of MAGTF subordinate elements.

G-2/S-2 Facilitation

The MAGTF intelligence officer enables effective use of IMINT and other intelligence and reconnaissance activities and products throughout the unit. The MAGTF intelligence officer has three key subordinate officers:

- Intelligence operations officer, who is responsible for managing the information flow between the battle staff and the commander, current and future operations sections, and force fires.
- Intelligence plans officer, who is responsible for supporting the future plans team.
- Intelligence battalion commander, who, as the AC/S G-2's ISC, has principal staff responsibility for both disseminating intelligence throughout the MAGTF and ensuring that intelligence is understood. He must also facilitate responses to any new CCIRs that may result.

Tailored and Timely Intelligence

The guiding principle that underpins all intelligence dissemination activities is to disseminate time sensitive intelligence products to the right people at the right time.

INTELLIGENCE AND IMAGERY INTELLIGENCE CYCLES

The intelligence and imagery intelligence cycle are processes that the Marine Corps uses to develop and utilize intelligence.

General

Intelligence is the output of a process that converts data and information into knowledge that impacts military decisions. The process used to develop intelligence is called the intelligence cycle (see fig. 1-1).

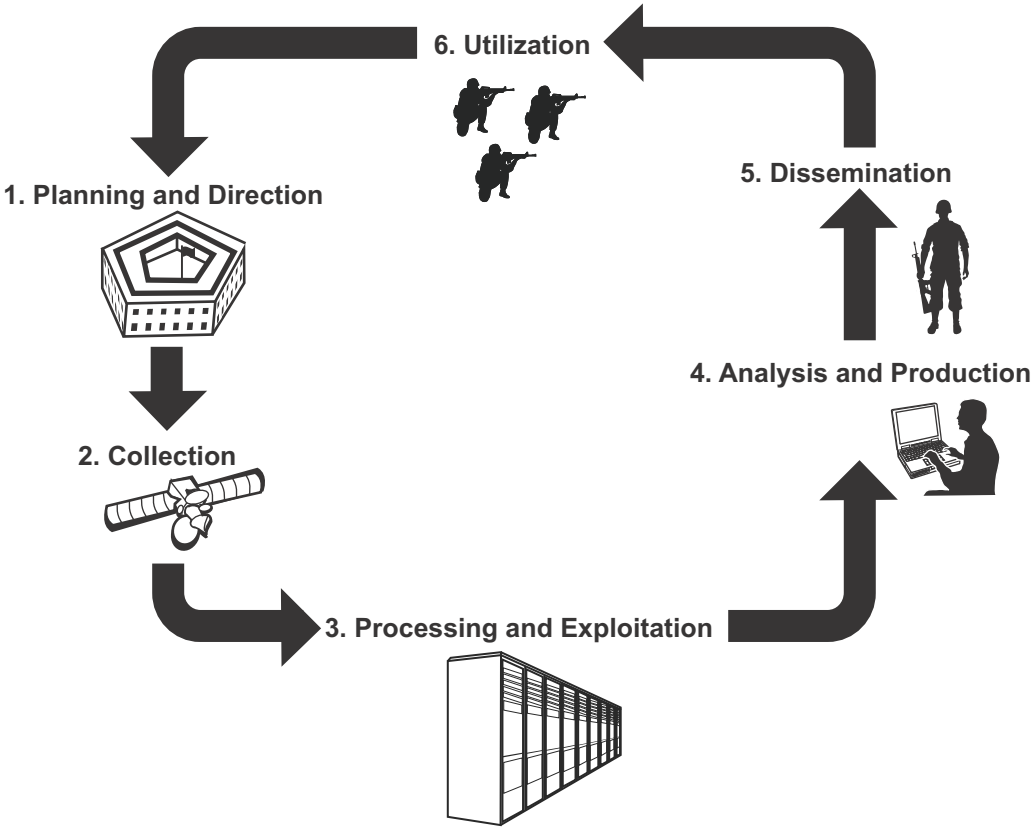

Figure 1-1. United States Marine Corps Intelligence Cycle.

The IMINT cycle mirrors the intelligence cycle. The steps in this cycle define a sequential, interdependent process for developing IMINT. Chapter 5 provides greater details on these cycles.

> ***Note:*** The steps in the Marine Corps intelligence cycle differ from those that constitute the joint intelligence cycle, which de-emphasizes the utilization step of the cycle in favor of continuous evaluation and feedback.

Tasking, Collection, Processing, Exploitation, and Dissemination Process

The TCPED process supports the flow of the intelligence cycle. It begins with the commander's request for information and ends with delivery of IMINT to the end-user. The success of the

TCPED process is tied to the decisionmaking cycle of that end-user (i.e., did the end-user get the IMINT needed to affect the commander's decision).

Tasking. Tasking is the process by which collection assets are assigned to collect against the commander's requirements. Additionally, it implies management of the entire TCPED process. Each user of imagery/GEOINT products will have distributed, seamless, and real-time access to existing databases located at each echelon of command. This access will show the user the coverage and types of information available. If no existing resources cover the requirement, then the user can request new imagery/imagery products (i.e., geospatial source information or a combination of products).

Collection. Collection managers (CMs) create, review, approve, and track imagery collection requirements. Imagery analysts determine whether or not imagery collection requirements have been satisfied and report user satisfaction to the CM.

Processing. Processing involves the conversion of collected data into information that is suitable for the production of intelligence. Processing is accomplished during collection and/or production. Some types of imagery data require minimal processing: they may be collected in a form that is already suitable for production. Other types of imagery data require extensive processing to incorporate amplifying data not available on the raw image products, which affects the timeliness and accuracy of the resulting information.

Exploitation. Exploitation is the extraction, analysis, and compilation of information from collected imagery to answer the CCIRs and EEIs as part of the IPB process. Exploitation occurs at all echelons of the MAGTF. Exploitation is the activity that converts information into intelligence.

The results of exploited and analyzed imagery and imagery data form the basis for IMINT reports and the derived products that are provided directly to tactical commanders, to the G-2/S-2 for inclusion into all-source intelligence products, and to other users. User needs are rarely satisfied by uninterpreted imagery; rather, IMINT exploitation planning and management should be coordinated with all-source intelligence production management and planning. The goal is effective and efficient use of limited resources while ensuring that IMINT production is focused on validated PIRs, intelligence requirements, and associated specified intelligence reporting criteria. This coordination includes:

- Determining the scope, content, and format for each product.
- Planning and scheduling the development of products.
- Assigning priorities among the various IMINT product requirements.
- Determining who needs what products and in what quantities.
- Allocating IMINT processing and exploitation resources.
- Coordinating production efforts with IMINT and all-source collection and dissemination activities.

Still frame imagery is exploited in the following three phases:

- First phase still frame imagery analysis is the rapid exploitation of newly acquired imagery and reporting of imagery-derived information (reconnaissance exploitation report [RECCEXREP]) within a specified time from receipt of imagery. This phase satisfies priority requirements of immediate need and/or identifies changes or activity of immediate significance. First phase still frame imagery analysis results in an initial photographic interpretation report (IPIR).
- Second phase still frame imagery analysis is the detailed exploitation of newly acquired imagery and the reporting of imagery-derived intelligence and information while meeting the production and timeliness requirements. Other intelligence discipline source material may support such imagery as appropriate. Second phase still frame imagery analysis yields a supplemental photographic interpretation report (SUPIR).
- Third phase still frame imagery analysis is the detailed analysis of all available imagery pertinent to a specific information requirement and the subsequent production and reporting resulting from this analysis within a specified time. This phase provides an organized detailed analysis of an imagery target or topic, using imagery as the primary data source but incorporating data from other sources as appropriate.

Likewise, motion imagery is exploited in the following three phases:

- First phase motion imagery analysis includes rapid, real-time callouts (i.e., size, activity, location, unit, time, and equipment [SALUTE] reports) of full motion video (FMV) via voice or chat.
- Second phase motion imagery analysis encompasses initial FMV annotated stills and video. Second phase motion imagery can supplement first phase motion imagery.
- Third phase motion imagery analysis includes in-depth analysis of FMV data, possibly fused with other sources, resulting in an intelligence product.

Dissemination. All echelons of the MAGTF generate information; therefore, the information must flow up and down the echelons of command. Dissemination is the process for providing the MAGTF and other users with products for all operations, including navigation, targeting, operational planning, mission rehearsal, and support to modeling and simulations. Imagery intelligence products are disseminated through all available delivery methods, including multisecurity level, Web-based, accessible storage devices that maintain imagery and IMINT relevant to the customer.

Imagery-Derived Products

Imagery-derived products are secondary products that can be disclosed and released to coalition partners. They are useful for a variety of planning and decisionmaking activities. Several of the most commonly requested products include beach studies, helicopter landing zone (HLZ) studies, and raid studies.

National Imagery Interpretability Rating Scale. Still and motion imagery are also rated for quality of the imagery acquired from various types of imaging systems. The National Imagery Interpretability Rating Scale (NIIRS) is considered the standard for rating image quality by most imagery analysts and scientists. The NIIRS defines different levels of image quality/ interpretability based on the types of tasks an analyst can perform with images of a given NIIRS

rating. The idea is that imagery analysts should be able to perform more demanding interpretation tasks as the quality of the imagery increases. Examples of these scales are in appendices D and E.

Imagery Intelligence Text Products. Imagery intelligence text products are selected to meet the specific needs of the commander. Appendix F provides the format and instructions for completing the RECCEXREP, the IPIR, and the SUPIR.

The RECCEXREP is used to report the results from the first rapid analysis of imagery, including the debriefing of the aircrew when possible. It addresses the targets requested in the original imagery collection mission tasking, normally with each target addressed separately. It is prepared by intelligence personnel, such as the imagery intelligence platoon (IIP), MAW, or Marine logistics group (MLG), based on input from the supporting collecting unit's intelligence section. The report is then disseminated in accordance with the dissemination plan. The specified time limit in which the RECCEXREP must be completed and disseminated must be in accordance with unit standing operating procedure (SOP).

The IPIR provides information regarding tasked imagery collection missions not previously reported (e.g., in the RECCEXREP); when extensive or detailed data from a systematic review of the imagery is required; or when the rapid response required by the RECCEXREP would be hindered by the format, size or quality of the imagery involved. It also is prepared by the IIP (with input from the supporting collecting unit's intelligence section) and disseminated in accordance with the dissemination plan. The timeline for completing this report will be in accordance with the unit SOP.

The SUPIR provides information not previously included in a RECCEXREP or IPIR. It reports on significant targets covered by the mission and other required supplemental data. It is prepared by intelligence personnel, such as the IIP, MAW, or MLG, based on input from the supporting collecting unit's intelligence section. The report is then disseminated in accordance with the dissemination plan. The specified time limit in which the SUPIR must be completed and disseminated will be in accordance with unit SOP.

Size, Activity, Location, Unit, Time, and Equipment Report. The standard SALUTE report is used to report any known or suspected enemy activity. It may also be used to report any characteristics of the AO that affect mission accomplishment. The SALUTE report may be used by a VMU, ground reconnaissance unit, aircrew, or other personnel to report key information obtained during ongoing imagery collection operations. This report will be disseminated in accordance with the dissemination plan: generally from the collector to the SARC or directly from the collector to other supported units.

G-2/S-2 Role in the Intelligence Cycle

Figure 1-2, on page 1-12, depicts the G-2/S-2 role in the intelligence cycle and highlights the relationship of IMINT to MAGTF intelligence requirements and operations. Intelligence requirements can be complex and challenging; rarely will a single intelligence discipline, source, or sensor provide the complete answer to a request. Specific data must be processed and all of the seemingly unrelated, individual pieces of information must be evaluated, analyzed, and integrated into a usable, fused, all-source intelligence product that satisfies particular CCIRs. The planning process is discussed in greater detail in chapter 5.

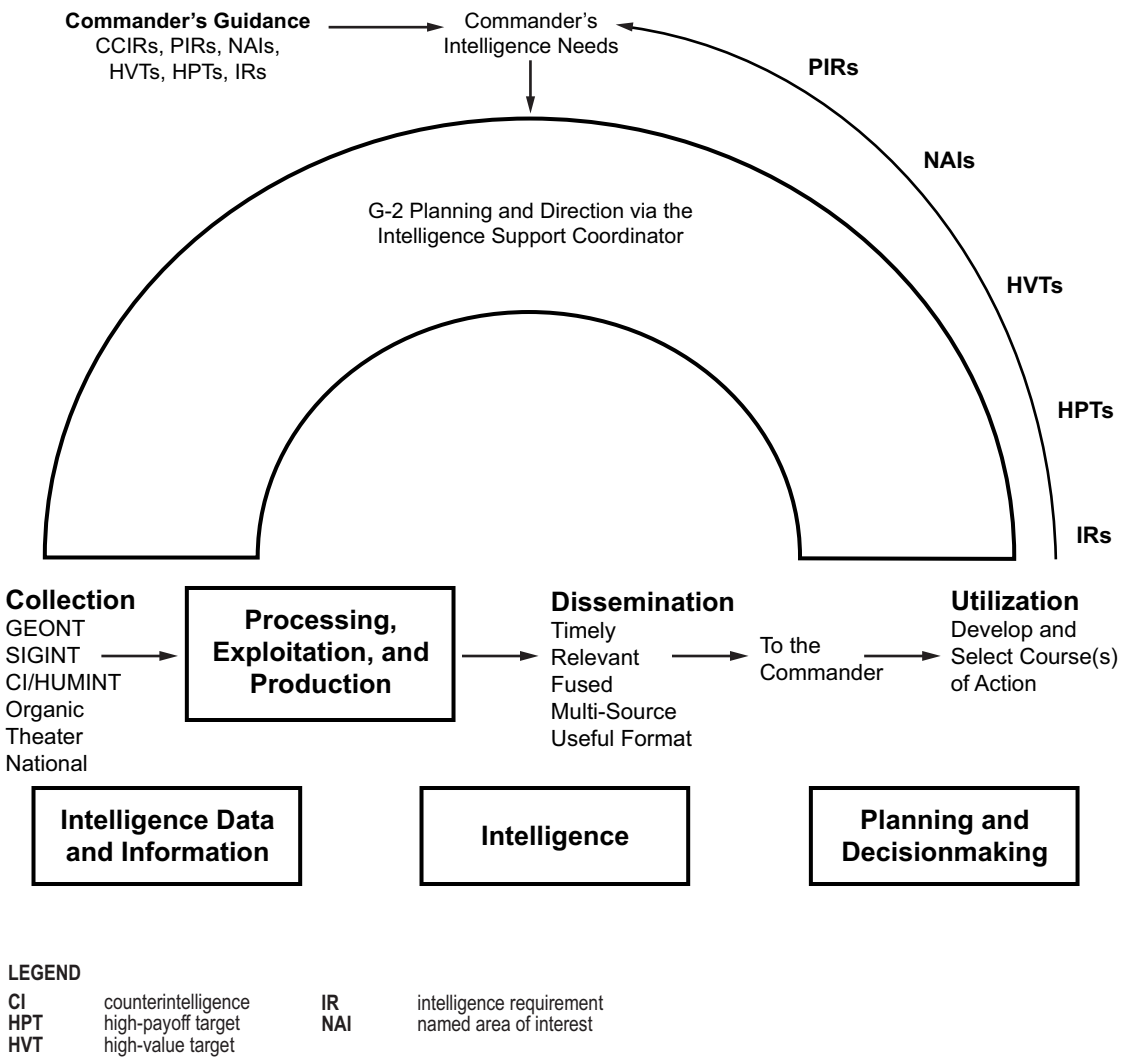

Figure 1-2. Intelligence Officer's Role in the Intelligence Cycle.

LEVELS OF IMAGERY INTELLIGENCE

The MAGTF relies on tactical, theater, and national imagery to support planning and operations. A goal of imagery architecture development is to ensure that imagery products are available to support the MAGTF during all phases of every operation, regardless of geographic location (see fig. 1-3 on page 1-13). External imagery support assists the MAGTF during pre-deployment planning and imagery archive development. It also enables the MAGTF to view denied portions of the AO. As the MAGTF transits to the AO, imagery support is provided by a combination of national and theater assets. Once a MAGTF is within the AO, its organic assets will take on a greater role in providing imagery support.

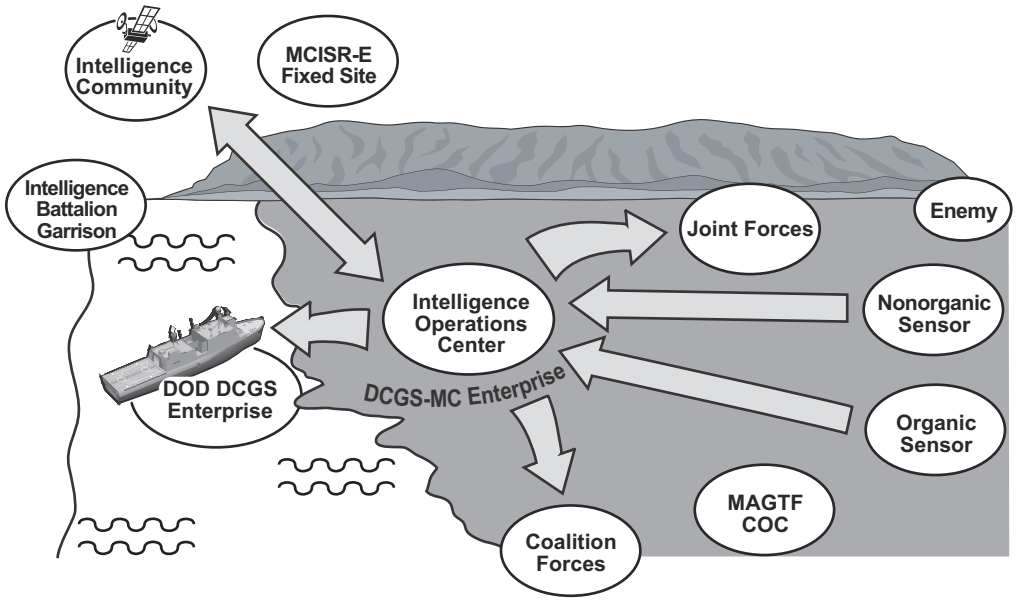

Figure 1-3. Imagery Architecture from IOC to COC.

National Imagery Intelligence

The MAGTF CMs submit requirements for national IMINT support to the appropriate departmental requirements office (DRO) via the appropriate operational chain of command (see fig. 1-4 on page 1-14 and fig. 1-5 on page 1-15). The DRO used is determined by the operational situation and operating environment. As a general rule, all continental United States-based exercises, pre-deployment planning, and/or requirements mandated by the United States Code, Title 10, *Armed Forces*, are submitted via the chain of command to the United States Marine Corps DRO. Once a MAGTF is underway or deployed, requirements are submitted via the operational command for action by the Defense Intelligence Agency (DIA) DRO.

Tactical Imagery Intelligence

Organic collectors of imagery and imagery-related information can support either routine or time-sensitive tactical intelligence. Because MAGTFs are task-organized, their organic capabilities and the degree of external support they require can vary.

Chapters 3 and 4 address Marine Corps imagery organizations and capabilities organic to MAGTFs. Examples of the types of external imagery support the MAGTF may require are discussed in the following subparagraphs.

Pre-deployment. The MAGTF may require the following pre-deployment support:

- MAGTF imagery storage devices loaded with current imagery.
- Pre-deployment packages (e.g., external hard drives, CD ROM[compact disc read-only memory]).

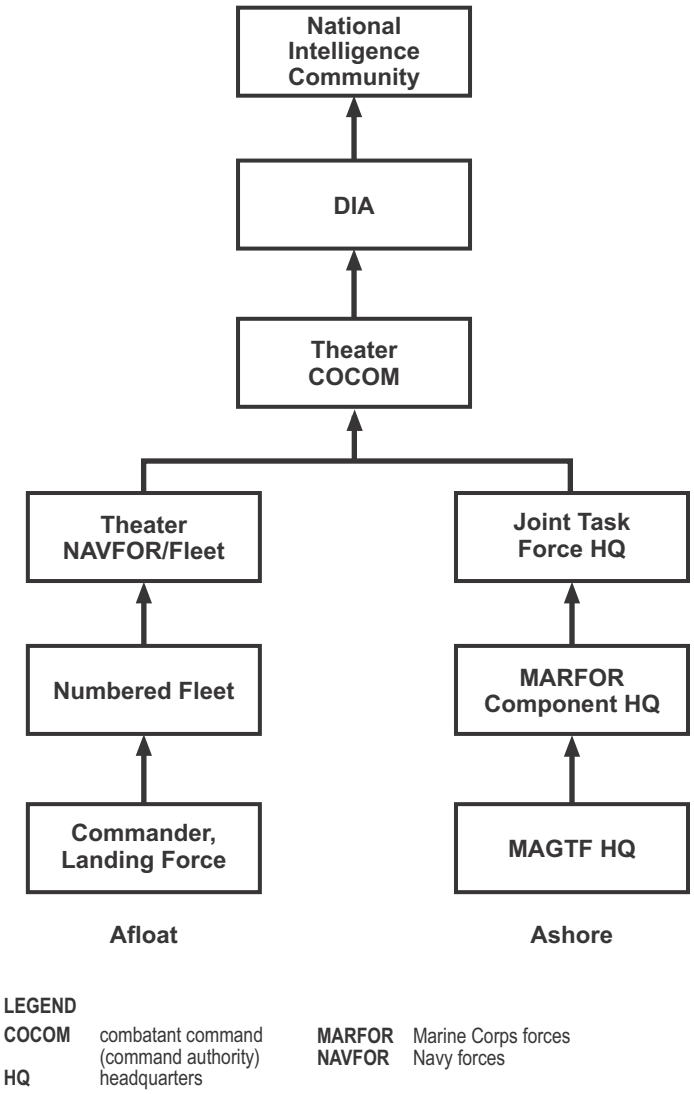

Figure 1-4. External Imagery Support Request Chain.

- Digital imagery database:
  - Area coverage baseline.
  - Baseline target/mission data.
  - Geospatial information.
  - Image maps.

En route to Area of Operations. The MAGTF may require the following support en route to the AO:

- Reachback capability for updated imagery.
- Automatic/profiled update.
- Target-update images.
- Special area imagery.

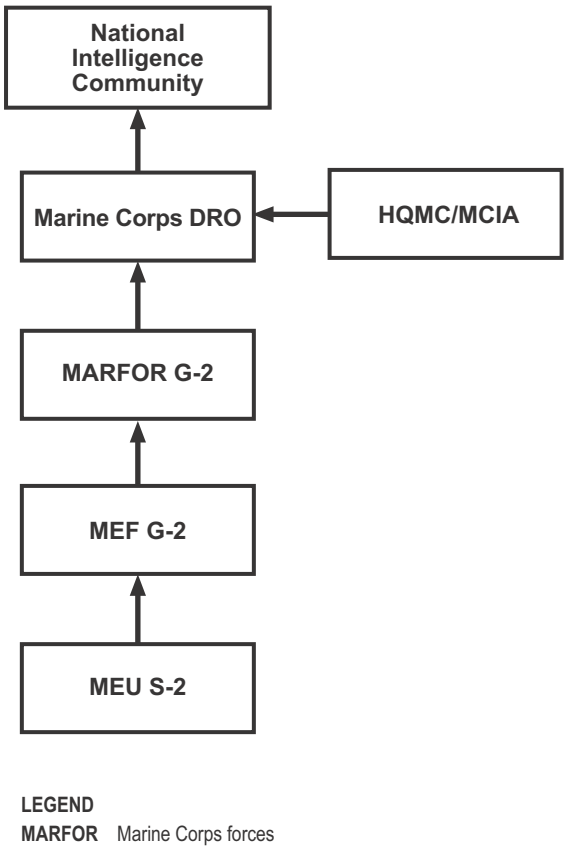

Figure 1-5. Internal Imagery Support Request Chain.

Area of Operations. The MAGTF may require the following support at the AO:

- Reachback and pull capabilities.
- MAGTF operations plan support:
  - Landing zone (LZ) analysis.
  - Mission planning.
  - All-source visualization.
- Air tasking order (ATO) cycle support, including special area imagery.

Theater Imagery Intelligence

Combatant commanders play a significant role in providing imagery support to MAGTFs due to the critical need for component interoperability during joint operations. Joint and theater IMINT is provided by the imagery assets organic to the combatant commander. Their joint intelligence operation centers (JIOCs) and joint analysis centers fulfill operational IMINT requirements of component, subordinate intelligence centers and joint task forces (JTFs).

CHAPTER 2
ORGANIZATIONS AND RESPONSIBILITIES

This chapter describes the roles and responsibilities of organizations and personnel conducting and supporting IMINT operations.

Marine Expeditionary Force Key Personnel Responsibilities

Within the MEF, the key personnel who have specific responsibilities for imagery intelligence operation are the commander, the G-2 staff and intelligence battalion, other staff sections, and intelligence officers at MEF major subordinate commands.

Role of the Commander

The responsibilities of the commander for imagery intelligence are command attention, intelligence requirements, resource allocation, and communications and information systems support.

Command Attention. Intelligence is an essential responsibility of command. The commander's involvement in the intelligence process includes focusing and supporting the intelligence effort, participating in the intelligence process, using intelligence, and providing personal evaluation of the intelligence effort.

Intelligence Requirements. The commander focuses intelligence in general and imagery collection in particular by communicating the commander's intent and planning guidance and the CCIRs, of which PIRs are a part. These later requirements drive all intelligence collection, production, and dissemination activities.

Resource Allocation. Imagery intelligence collection platforms are a high demand, low density asset. Some MAGTF imagery collection platforms have additional mission roles. Consequently, they may be tasked to perform command and control, targeting, electronic warfare (EW), or other intelligence collection missions in addition to imagery collection. Therefore, when it comes to IMINT operations, the commander's role in mission prioritization of organic imagery airborne collection and other IMINT assets is particularly important. A logical, detailed, and realistic concept of intelligence support, developed in accordance with the commander's intent and CONOPS, will facilitate the appropriate allocation of intelligence capabilities between the MAGTF's main and supporting efforts, as well as between intelligence support to current operations and the planning efforts for future operations.

Communications and Information Systems Support. The commander must assess the communication and information systems (CIS) requirements for intelligence against all competing MAGTF CIS's needs to ensure the required support is provided. Ultimately, the extent to which a MAGTF can request/receive JTF, theater, and national imagery support is a function of the connectivity and throughput of this CIS from the tactical level to theater and national levels.

Marine Expeditionary Force Command Element: G-2 Section and the Intelligence Battalion

Within the G-2 section and intelligence battalion, key personnel that have specific responsibilities for imagery intelligence operation are the AC/S G-2, G-2 operations officers, G-2 plans officer, intelligence battalion commander/intelligence support coordinator, collection management/ dissemination officer, surveillance and reconnaissance center officer in charge (OIC), the production and analysis company commander, and the imagery intelligence platoon commander.

Assistant Chief of Staff G-2. The AC/S G-2 has staff responsibility for intelligence and intelligence operations—including IMINT (see fig. 2-1 on page 2-3 and fig. 2-2 on page 2-4). The commander relies on the intelligence officer to keep him informed about the weather and terrain, as well as the capabilities, status, and intentions of enemy forces. The MEF AC/S G-2 uses the intelligence operations plan to formulate and validate intelligence requirements; coordinate intelligence priorities; integrate collection, production, and dissemination activities; allocate resources; assign specific intelligence and reconnaissance missions to subordinate elements; and supervise all intelligence and reconnaissance efforts. The key all-source and IMINT responsibilities of the AC/S G-2 include—

- Developing and answering outstanding CCIRs, PIRs, and intelligence requirements by planning, directing, integrating, and supervising organic IMINT and multidiscipline intelligence operations conducted by the MEF and supporting organizations.
- Preparing appropriate IMINT and other intelligence and reconnaissance plans and orders for the MEF, and reviewing and coordinating the IMINT and all-source intelligence plans developed by other organizations.
- Submitting requests to higher headquarters for JTF, theater/national IMINT systems to support all-source and IMINT collection, production, and dissemination requirements.
- Ensuring IMINT/other intelligence information is processed, analyzed, incorporated (where appropriate in all-source intelligence products), and disseminated to appropriate MEF and external units.
- Evaluating JTF, theater, and national IMINT and all-source intelligence support and adjusting stated intelligence requirements when necessary.
- Identifying and correcting deficiencies in IMINT and other intelligence and reconnaissance personnel and equipment.
- Incorporating exercise IMINT into training exercises to improve individual, collective, and unit readiness within the MEF.
- Facilitating the use of IMINT and other intelligence to support the planning and execution of MEF operations.

G-2 Operations Officer. The G-2 operations officer works directly for the AC/S G-2 and provides support to the commander and the MEF command element for current and future operations. The all-source and IMINT responsibilities of the G-2 operations officer include—

- Coordinating and providing intelligence support (including key IMINT support) to the commanding general, the G-3 operations section, and the remaining MEF command element battle staff.
- Serving as the G-2 representative to the MEF command element crisis action team.

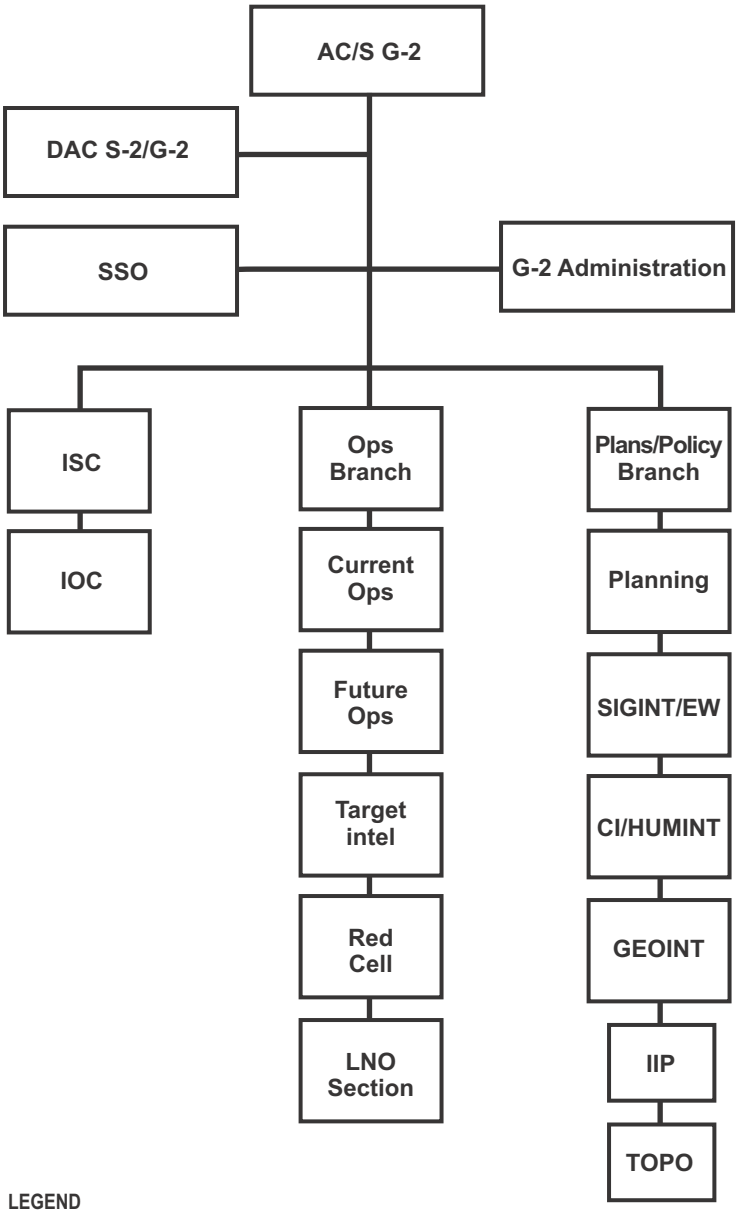

Figure 2-1. Marine Expeditionary Force G-2 Division Principal Staff Officers and Relationships.

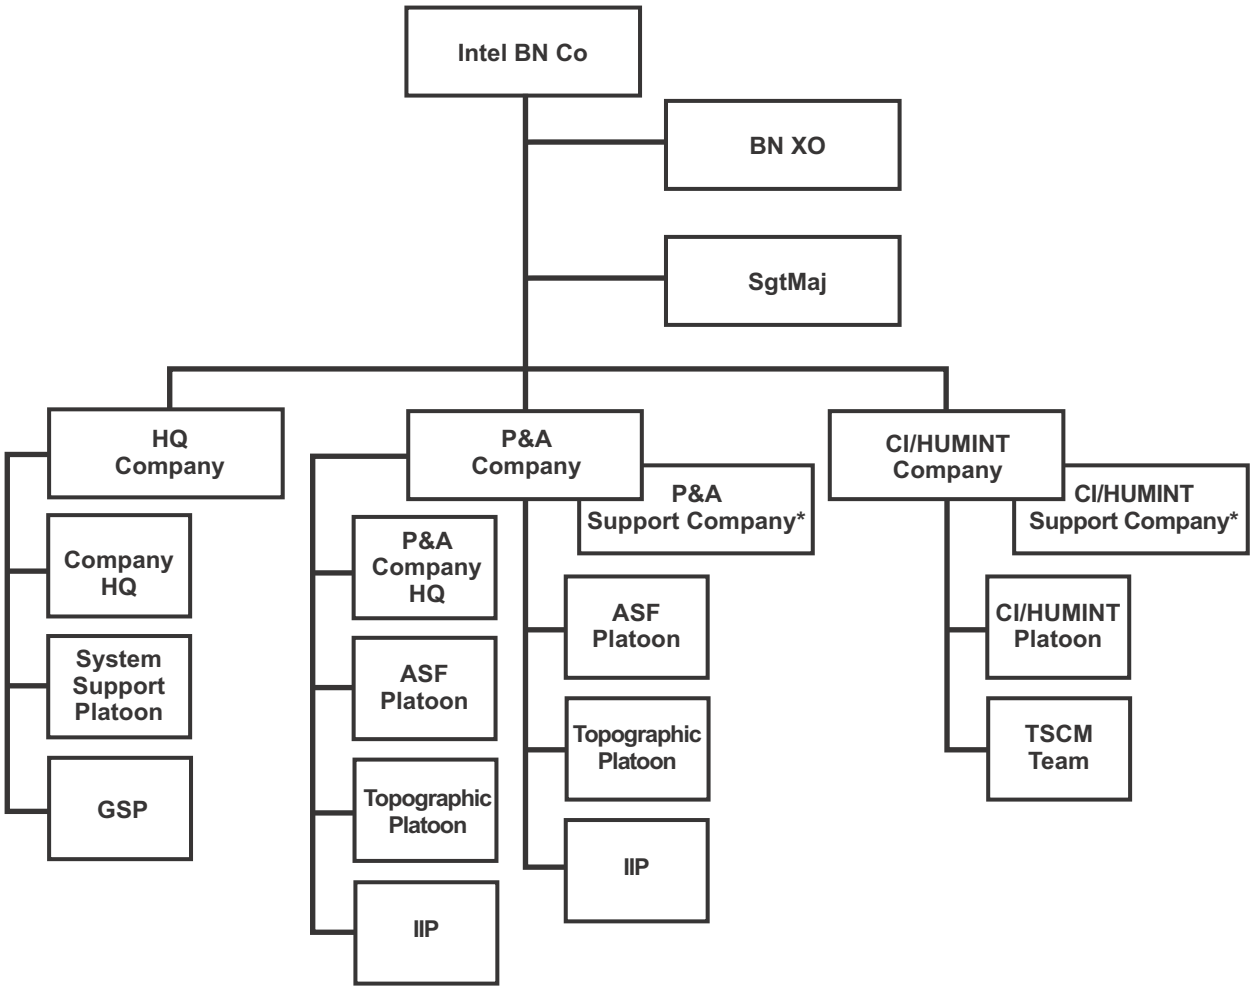
- Providing, coordinating, and supervising intelligence support to the MEF command element combat operations center (COC), future operations cell (FOC), and force fires.
- Planning, directing, and supervising the threat or red cell.
- Providing recommendations regarding CCIR, PIR, and intelligence requirement validation, prioritization, and tasking to both the AC/S G-2 and the ISC.
- Coordinating and supervising the transition of intelligence planning and operations from G-2 plans to G-2 future operations, and from G-2 future operations to G-2 current operations, in order to support the MEF's single battle transition process.



*3d Intelligence Battalion does not have a P&A support company or a CI/HUMINT support company.

Figure 2-2. Intelligence Battalion.

- Planning, directing, and supervising MEF liaison officers or teams to external commands (e.g., the JTF and joint functional components headquarters) and intelligence organizations.
- Coordinating with the operations officers and MEF major subordinate commands (MSC) G-2/S-2s to ensure unity of effort of all MEF intelligence operations.
- Providing intelligence input and other support to MEF warning and fragmentary orders and to all other operations-related reporting (e.g., periodic situation reports).
- Coordinating intelligence training for the MEF G-2 section and providing oversight for and implementation of the MEF G-2 intelligence training program.
- Accomplishing other intelligence support tasks as directed by the AC/S G-2.

G-2 Plans Officer. The G-2 plans officer works directly for the AC/S G-2 and provides intelligence support to the G-3 future plans cell. The key all-source and IMINT responsibilities of the G-2 plans officer include—

- Planning the MEF concept of intelligence operations for approval by the AC/S G-2, and its subsequent implementation by the ISC based upon the mission, threat, commander's intent, guidance, and CONOPS. This concept of intelligence operations includes a supporting IMINT CONOPS.
- Leading, coordinating, and providing intelligence support to the MEF G-5 future plans section.
- Planning and coordinating intelligence support requirements for the deployment of intelligence elements and resources into the AO.
- Providing recommendations regarding PIR and intelligence requirement validation, prioritization, and taskings to both the AC/S G-2 and the ISC.
- Coordinating with the ISC and G-2 to develop the Annex B (Intelligence), Annex H (METOC), and Annex M (GI&S), as well as their supporting appendices (e.g., Appendix 7, Imagery Intelligence), of MEF operation plans (OPLANs). And in addition, providing intelligence input to other annexes of MEF OPLANs.
- Keeping the G-2 section, other command element staff sections, intelligence liaison personnel, augmentees, and personnel apprised of MEF intelligence planning actions and requirements.
- Identifying requirements and providing recommendations to the G-2 operations officer regarding MEF intelligence liaison teams to external commands (e.g., the JTF or other component headquarters) and intelligence agencies.
- Coordinating and developing policies for MEF intelligence, counterintelligence, and reconnaissance operations.
- Planning, directing, and supervising the MEF G-2's GEOINT (i.e., imagery, METOC, and GI&S), counterintelligence/HUMINT, and SIGINT.
- Accomplishing other intelligence support tasks, as directed by the AC/S G-2.

Intelligence Battalion Commander/Intelligence Support Coordinator. The intelligence battalion commander is responsible for TCPED of intelligence and for providing counterintelligence support to the MEF, MEF MSCs, subordinate MAGTFs, and other commands, as directed. While in garrison, the intelligence battalion commander is responsible for organizing, training, and equipping detachments that will support either MAGTFs or other designated commands by executing integrated collection, intelligence analysis, production, and dissemination of intelligence products.

While operational, the intelligence battalion commander is dual-hatted, also serving as the ISC under the direct staff cognizance of the MEF AC/S G-2. As the ISC, the intelligence battalion commander is responsible to the MEF AC/S G-2 for the overall planning and execution of MEF

all-source intelligence operations. Specific all-source and key IMINT responsibilities of the ISC during actual operations include—

- Implementing the concept of intelligence operations developed by the G-2 plans officer and approved by the AC/S G-2.
- Establishing and supervising operation of the MEF IOC (see fig. 2-3), which includes the support cell, the SARC, and the P&A cell. The IOC will normally be collocated with the MEF command element's main command post.
- Developing, consolidating, validating, and prioritizing recommended PIRs and intelligence requirements to support MAGTF planning and operations.
- Planning, developing, integrating, and coordinating MEF intelligence collection, production, and dissemination plans. Such plans include the effective organic and external integration and employment of MAGTF IMINT as well as staff cognizance of MEF GEOINT; counterintelligence; HUMINT; SIGINT; ground sensor platoon; ground reconnaissance; and tactical air reconnaissance intelligence collections, production, and dissemination operations.

Figure 2-3. Intelligence Operations Center.

- Developing, in conjunction with the G-2 operations officer and G-2 plans officer, Annex B (Intelligence), Annex H (METOC), and Annex M (GI&S), as well as their supporting appendices (e.g., Appendix 7, Imagery Intelligence), of MEF operation orders (OPORDs). And in addition, providing intelligence input to other annexes of MEF OPORDs.
- Planning, developing, integrating, and coordinating intelligence and counterintelligence support for the commander's estimate, situation development, I&W, force protection, targeting, and combat assessment.
- Managing and fusing the threat inputs from subordinate units, external commands, and intelligence agencies into the MEF COP/common tactical picture (CTP).
- Providing intelligence support to the G-2 sections at both the MEF and its MSCs.
- Preparing intelligence and counterintelligence estimates to support G-2 plans.
- Planning, developing, and coordinating intelligence CIS architecture, including its integration with and support of MEF IMINT and other intelligence and reconnaissance requirements.
- Coordinating and integrating MEF IMINT and all-source intelligence operations with other Service components, JTF, the joint intelligence support element (JISE), theater JIOC or joint analysis center, and national intelligence agencies, including all aspects of intelligence reachback support such as the Marine Corps Intelligence Activity (MCIA).
- Assisting with the evaluation and improvement of both MEF IMINT and all-source intelligence operations.
- Accomplishing other intelligence support tasks as directed by the AC/S G-2.

Collection Management/Dissemination Officer. The collection management/dissemination officer (CM/DO) is sourced from the S-3 section of the intelligence battalion. The CM/DO is a key subordinate to the intelligence battalion commander/ISC during operations. The CM/DO is responsible for formulating detailed intelligence collection requirements (ICRs) and intelligence dissemination requirements. He is also responsible for tasking and coordinating internal and external operations to satisfy these requirements.

The CM/DO receives PIRs, intelligence requirements, and direction from the ISC; he then plans and manages the employment of organic and supporting collection and dissemination resources (Appendix 16, Intelligence Operations Plan, to Annex B [Intelligence]). Additionally, the CM/DO is responsible for validating and forwarding MEF and MSC collection requests for theater and national IMINT to the appropriate agencies for action. The CM/DO is responsible for coordinating intelligence CIS requirements and maintaining awareness of available CIS connectivity both inside the MAGTF and with key external organizations. During operations, the CM/DO works within the support cell. The CM/DO (in coordination with the P&A company commander, the SARC OIC, G-2 operations officer, and the G-6) determines and coordinates the collection effort of PIRs/ intelligence requirements. The CM/DO is responsible to the ISC for the following several important IMINT-related tasks:

- Recommending dissemination priorities, developing intelligence reporting criteria, and advising on and selecting dissemination means.
- Developing and coordinating IMINT and all-source intelligence collection plans; coordinating and integrating these plans with MEF, other component, JTF, theater, and national intelligence production operations.

- Developing and coordinating IMINT and all-source intelligence dissemination plans and supporting networked communications architectures and coordinating and integrating these requirements with MEF, other component, JTF, theater, and national intelligence CIS and dissemination operations.
- Monitoring the flow of imagery requirements throughout the MAGTF and ensuring imagery products are delivered in a timely manner.
- Evaluating the effectiveness of MEF and supporting IMINT collection and dissemination operations.

Surveillance and Reconnaissance Center Officer in Charge. The SARC OIC supervises the execution of intelligence collection and reconnaissance operations conducted by organic, attached, and direct support assets. The SARC OIC is responsible to the ISC for accomplishing the following specific IMINT-related tasks:

- Coordinating, monitoring, and maintaining the status of all ongoing organic imagery collection operations, including the following:
  - Missions, tasked ICRs, and reporting criteria for collection missions.
  - Locations and times for all pertinent fire support control measures.
  - Primary and alternate CIS plans, which support both routine and time-sensitive requirements for IMINT collectors.
- Ensuring other MAGTF command and control (C2) nodes, such as the current operations center or force fires, are apprised of ongoing IMINT and other intelligence and reconnaissance operations.
- Receiving routine, time-sensitive IMINT-related reports from dispersed collection elements and cross-cueing among intelligence collectors.
- Disseminating IMINT reports according to standing PIR/intelligence requirements, intelligence reporting criteria, dissemination plans, and the current tactical situation.

Production and Analysis Company Commander. The P&A company commander has primary responsibility for coordinating intelligence processing and production requirements directed by the MEF, including the following:

- Planning, directing, and managing operations of the all-source fusion platoon (AFP), IIP, METOC, topographic platoon, direct support teams, and other P&A elements, as directed.
- Coordinating and integrating P&A company operations, estimates, and products with the MEF G-2 sections.
- Planning, managing, and maintaining all-source and GEOINT data.
- Operating, maintaining, and integrating intelligence processing and production systems.
- Analyzing and fusing GEOINT with other intelligence to create tailored all-source intelligence products that satisfy all supported commanders' PIRs and intelligence requirements.

- Developing and maintaining current and future intelligence situational, threat, and environmental assessments and target intelligence based upon all-source analysis, interpretation, and integration.
- Managing and fusing the threat COP/CTP inputs from subordinate units, external commands, and intelligence agencies into the MEF command element's threat COP/CTP.

Imagery Intelligence Platoon Commander. The IIP commander is responsible for planning and providing the MEF, and other commands as directed, with imagery products to support operations. Tasks specific to the IIP commander include the following:

- Exploiting and analyzing all-source, multisensor imagery to derive intelligence pertaining to installations, dispositions, strengths, and activities of various conventional and nonconventional forces.
- Planning and tasking multisensor platforms (both organic platforms and platforms external to the MAGTF).
- Managing imagery data and exploitation.
- Providing imagery-derived products and reports to the MEF commander and other pertinent commanders.
- Conducting liaison activities with the Service intelligence center and pertinent external agencies to obtain imagery products that support MEF intelligence requirements.

Marine Expeditionary Force Command Element: Other Staff Sections

Other staff sections that have specific responsibilities for imagery intelligence are AC/S G-1, AC/S G-3, AC/S G-4, AC/S G-5, and AC/S G-6.

Assistant Chief of Staff G-1—Personnel Section. The AC/S G-1 provides personnel support to the IMINT effort, including coordinating augmentation by qualified personnel. Requests for IMINT personnel augmentation will be developed by the MEF AC/S G-2 and provided to the AC/S G-1 for either internal sourcing or forwarding to higher headquarters for global sourcing.

Assistant Chief of Staff G-3—Operations Section. The AC/S G-3 is responsible for planning, coordinating, and supervising the movement and employment of maneuver units and fires. Imagery intelligence provides valuable support for each of those tasks. Consequently, G-3 personnel must understand the capabilities of the various IMINT collection systems, exploitation capabilities and requirements, and the advantages and limitations of different types of imagery and IMINT products. Additionally, when planning current and future operations, the movement and employment of IMINT personnel and their supporting units must be coordinated between the AC/S G-2 and G-3. Since some imagery supporting units also provide nonintelligence capabilities, close coordination between the AC/S G-2 and G-3 is necessary for mission prioritization and deconfliction.

Assistant Chief of Staff G-4—Logistics Section. The AC/S G-4 is responsible for the logistic support of attached IMINT units. All policies, procedures, and other support requirements should be coordinated between the G-4 and the supported IMINT personnel as soon as possible. Special attention should be directed towards logistic requirements related to the unique (i.e., large/bulky) equipment organic to IMINT units.

Assistant Chief of Staff G-5—Future Plans Section. The AC/S G-5 is responsible for all long-range (i.e., future) planning and joint planning matters. Normally, an AC/S G-5 is found only at the MEF and Marine Forces levels; at lower echelons of the MEF, the AC/S G-3 is responsible for the future planning task. Assistant chief of staff G-5 personnel must understand the capabilities of the various IMINT collection systems, exploitation capabilities and requirements, and the advantages and limitations of different types of imagery and IMINT products.

Assistant Chief of Staff G-6—Communications Systems Section. The AC/S G-6 provides and protects interior and exterior CIS connectivity and operations for the MEF, which includes providing the communication pathways, network accesses, and frequencies for IMINT organizations organic, attached to, and/or supporting the command. Therefore, the AC/S G-6 requires significant systems knowledge across IMINT and all-source intelligence CIS.

Intelligence Officers at Marine Expeditionary Force Major Subordinate Commands

The MSC intelligence officers must understand imagery and IMINT, as well as their capabilities and uses. Additionally, they must be able to integrate IMINT support with other command intelligence and reconnaissance operations. Close coordination among all unit intelligence officers can identify opportunities where small adjustments to IMINT requirements yield results that satisfy the collection/production tasks for more than one unit. Key IMINT-related tasks for MSC intelligence officers include—

- Planning and implementing a concept for intelligence support based on the mission, CONOPS, and commander's intent.
- Providing centralized direction for command intelligence operations, including IMINT elements attached to/placed in direct support of the unit.
- Consolidating, validating, and prioritizing unit intelligence requirements and IMINT needs.
- Submitting consolidated requests for external IMINT support to the MEF command element.
- Coordinating operational and CIS links in support of external IMINT collection and production elements and operations.
- Providing timely and accurate feedback from supported units regarding their level of satisfaction with the IMINT support provided.

NATIONAL IMAGERY ORGANIZATIONS

The national imagery organizations are the Office of the Director of National Intelligence, National Geospatial-Intelligence Agency (NGA), national intelligence support team (NIST), the National Reconnaissance Office (NRO), and the DIA.

Office of the Director of National Intelligence

Two elements of the Office of the Director of National Intelligence are the Director of National Intelligence (DNI) and the DNI organization.

The Director of National Intelligence. The DNI serves as the head of the intelligence community (IC) and is the principal advisor to the President, the National Security Council, and the Homeland Security Council for intelligence matters related to national security. Additionally, the DNI both oversees and directs the implementation of the National Intelligence Program. The President appoints the DNI and the principal deputy director with the advice and consent of the Senate. The responsibilities of the Director of National Intelligence include—

- Leading the IC.
- Overseeing the coordination of foreign relationships between elements of the IC and the intelligence services of foreign governments.
- Establishing requirements and priorities for collection, analysis, production, and dissemination of national intelligence.
- Coordinating reform of security clearance and acquisition processes.
- Ensuring IC financial statements are auditable.
- Supporting legislative, legal, and administrative requirements.
- Ensuring compliance with statutory and Presidentially-mandated responsibilities.
- Transforming the IC into a unified, collaborative, and coordinated enterprise.

Director of National Intelligence Organization. The DNI organization is composed of the DNI staff and IC mission and support activities. The DNI staff is responsible for developing IC policy and overseeing its implementation. It is also responsible for preparing the National Intelligence Program budget. The mission and support activities are responsible for providing IC-wide substantive intelligence, counterintelligence strategy and strategic analysis, research and development, and training and education. The Director of Intelligence (DIRINT) staff is responsible for synchronizing and integrating efforts across Office of the Director of National Intelligence.

National Geospatial-Intelligence Agency

The NGA has specific authorities, produces various products, provides various services, manages the GEOINT workforce, and provides deployable support teams.

National Geospatial-Intelligence Agency Authorities. By law, the NGA is a combat support agency (CSA) as well as a national intelligence organization. As functional manager of GEOINT, the NGA is directly subordinate to the Secretary of Defense and the Under Secretary of Defense for Intelligence. The NGA is the primary source for GEOINT analysis and products at the national level. In addition to the GEOINT support identified in Joint Publication (JP) 2-01, *Joint and National Intelligence Support to Military Operations*, the NGA supports national and homeland security, defense policy and force structure, and advanced weapons and systems development.

National Geospatial-Intelligence Agency Products. The NGA disseminates data and standard products. It also makes them available in repositories where GEOINT-trained personnel throughout the IC, including military personnel in the field, can access the data to develop their own GEOINT analysis and nonstandard products.

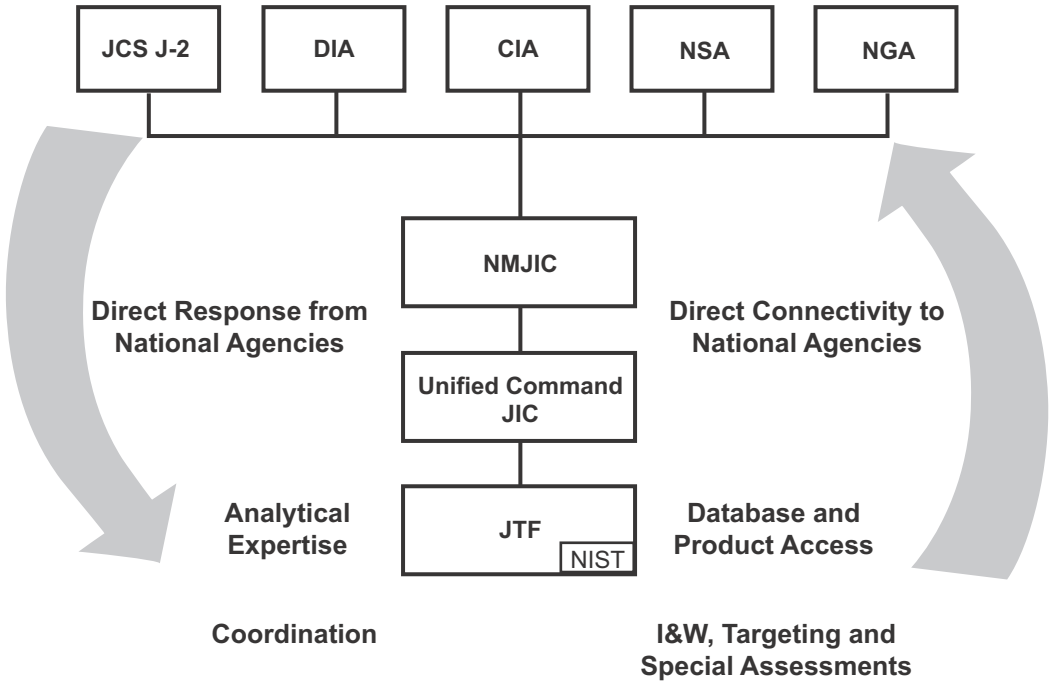
National Geospatial-Intelligence Agency Services. The NGA works with commercial imagery and geospatial data vendors to procure diverse unclassified imagery and geospatial information to support its customers, collaborative efforts with allies and coalition partners, other IC agencies, Department of Defense (DOD) organizations, and other civil and government entities.

National Geospatial-Intelligence Agency Workforce. The NGA provides GEOINT strategic workforce planning and specific training for general and specialized tradecraft skills through the National Geospatial-Intelligence College.

National Geospatial-Intelligence Agency Deployable Support. The NGA deploys a National Geospatial-Intelligence Agency support team (NST) in direct support of the Services, other IC organizations, and the JIOC at each combatant command (CCMD).

National Intelligence Support Team

National intelligence support teams are task-organized, national-level, all-source intelligence teams—generally consisting of DIA, National Security Agency (NSA), Central Intelligence Agency (CIA), and NGA personnel and equipment. They provide deployed commanders (generally at the JTF headquarters level) with coordination with national intelligence agencies, analytical expertise, I&W, special assessments, targeting support, streamlined and rapid access to national intelligence databases and other products, and assistance facilitating request for intelligence (RFI) management (see fig. 2-4).



LEGEND

JCS	Joint Chiefs of Staff
JIC	joint information center
NMJIC	National Military Joint Intelligence Center

Figure 2-4. National Intelligence Support Team Capabilities.

National Intelligence Support Teams Command and Control. National intelligence support teams are managed by the DIA's defense joint IOC. The DIA, through the joint staff J-2, controls each NIST for deployment and administrative purposes. See figure 2-5 for an overview of a NIST's deployment cycle.

During operations, a NIST will typically be in direct support of the joint force commander (JFC). The NIST falls under the staff cognizance of the JTF J-2, performing intelligence support functions as tasked. The basic NIST CONOPS is to take the JTF J-2's RFIs and collection and production requirements and discuss and deconflict these within the NIST to determine which element(s) should fulfill these requirements.

Each NIST element leader will maintain contact with their parent national intelligence organization and coordinate their actions with the NIST team chief. Intelligence generated by the NIST is available to the JTF J-2 JISE, the JFC, and other elements of the JTF with the usual caveats (i.e., restriction based on clearance and programs).

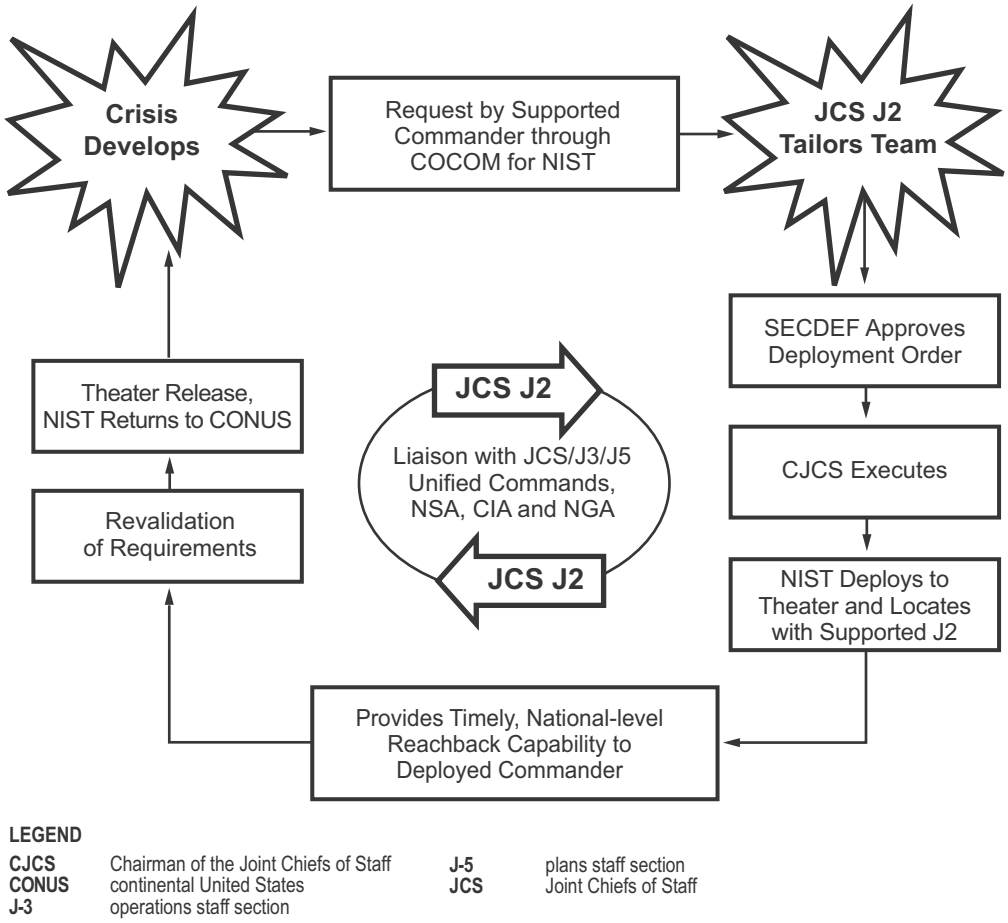


Figure 2-5. National Intelligence Support Team Deployment Cycle.

National Intelligence Support Teams Composition and Capabilities. The composition and capabilities of each deployed NIST are dictated by the mission, duration of the deployment, agencies represented, and capabilities required (see table 2-1). A NIST is not a self-contained element; it requires logistic and other support from the supported command (e.g., information systems technical support and an access-controlled secure area generally within the supported unit's tactical sensitive compartmented information facility).

Table 2-1. Notional Composition of a National Intelligence Support Team.

CIA	CIA
2 analysts 2 communicators Associated communications and information systems workstations	2 analysts 2 communicators Associated communications and information systems workstations
NSA	**NSA**
5–12 personnel (analysts, technicians, and communicators) Associated communications and information systems workstations	1 imagery analyst 1 geospatial analyst Associated communications and information systems workstations
Each NIST is task-organized to fulfill the supported commander's intelligence requirements.	

A NIST's organic capabilities generally encompass only intelligence and some unique CIS support. A NIST's CIS capabilities are task-organized and a NIST may range from a single agency element's voice connectivity to a fully-equipped NIST with JISE and Joint Worldwide Intelligence Communications System (JWICS) mobile integrated communications system video teleconferencing capabilities. For an example of the NIST's deployed footprint with the JWICS Mobile Integrated Communications System, see figure 2-6. Current methods of operation rely on both agency and supported command-provided communications pathways to support the deployed NIST element.

Figure 2-6. National Intelligence Support Team Joint Worldwide Intelligence Communications System Mobile Integrated Communications.

National Reconnaissance Office

The NRO designs, builds, and operates the nation's reconnaissance satellites. These satellites comprise one of the primary collection sources for GEOINT data and provide significant imagery to support DOD requirements related to targeting and mapping. These data are used for I&W, monitoring of arms control agreements, and the planning and execution of military operations. Once GEOINT data is collected, processed, and stored, the NGA takes the lead with respect to analysis and access/distribution for both national and DOD customers.

Defense Intelligence Agency

The DIA is both a national and defense-level intelligence agency. It is also designated as a CSA. The DIA is subordinate to the Secretary of Defense and the Under Secretary of Defense for Intelligence. The DIA has various programs that it manages and has certain responsibilities and management roles within the IC.

Defense Intelligence Agency Programs. The Director, DIA is the program manager of the General Defense Intelligence Program, which provides funding for the DIA and the intelligence organizations of each military department. The Director, DIA also manages a DIA program in the Military Intelligence Program, which includes select DIA programs and the intelligence resources of the eleven CCMDs. The Military Intelligence Program manages more than 500 military imagery analysts in support of the CCMDs.

Defense Intelligence Agency Responsibilities. The Director, DIA is responsible for coordinating collection requirements between national-level organizations and theater users for national and airborne imagery.

Defense Intelligence Agency Functional Management. The Director, DIA is the functional manager for the non-GEOINT-related components of measurement and signature intelligence (MASINT).

MARINE CORPS SUPPORTING ESTABLISHMENT IMAGERY INTELLIGENCE ORGANIZATIONS

The supporting establishment imagery intelligence organizations in the Marine Corps are Headquarters, Deputy Commandant for Capabilities Development and Integration; Systems Command; MCIA; and NSTs.

Headquarters, United States Marine Corps

Within Headquarters, United States Marine Corps (HQMC) there are two organizations that focus on imagery intelligence, Headquarters, Marine Corps-Imagery & Geospatial Intelligence Branch (HQMC-IPI) and HQMC, Department of Aviation.

Imagery/Geospatial Plans and Policies Branch, Intelligence Department. The HQMC-IPI serves as the principal Marine Corps representative for the DIRINT within the national and joint GEOINT communities. The HQMC-IPI personnel are responsible for developing and coordinating Marine

Corps imagery and geospatial programs. Specific HQMC-IPI personnel responsibilities include the following:

External to the Marine Corps

- Representing the DIRINT in meetings with the national agencies and other Services regarding policies affecting the planning and direction, collection, processing and production, dissemination, and utilization of GEOINT.
- Coordinating and validating Marine Corps Service-level imagery special collections and standing requirements for submission to the NGA source directorate.
- Ensuring Marine Corps imagery and geospatial intelligence architectures are interoperable with primary and alternate national imagery dissemination paths.
- Conducting liaison with the NGA and the CIA Office of General Counsel regarding matters related to IMINT oversight and domestic coverage.
- Responding to the Freedom of Information Act Office for requests to the Marine Corps for imagery materials, products, and derivative textual information/analytical methodologies.

Internal to the Marine Corps

- Identifying and coordinating issues related to intra-Service imagery and geospatial intelligence to ensure that organic resources available to the Marine Corps are exploited fully.
- Establishing policy guidance for disseminating national-level imagery to the operating forces afloat or ashore.
- Coordinating with the Deputy Commandant for Combat Development and Integration, Capabilities Development Directorate, Marine Corps Systems Command (MARCORSYSCOM) and other HQMC staff elements on imagery and geospatial intelligence issues related to—
  - GEOINT requirements and capabilities.
  - Dissemination architectures.
  - The Marine Corps Concept Based Requirements System process for GEOINT.
- Sponsoring the annual Marine Corps GEOINT conference.

Headquarters, Marine Corps, Department of Aviation. The Deputy Commandant for Aviation coordinates with Navy aviation elements to procure manned and unmanned tactical aviation platforms and sensors.

Deputy Commandant for Combat Development and Integration

The Deputy Commandant for Combat Development and Integration develops fully integrated warfighting capabilities—including doctrine, organization, training, materiel, leadership and education, personnel, and facilities—to enable the Marine Corps to field combat-ready forces.

Marine Corps Systems Command

Marine Corps Systems Command serves as the Commandant's principal agent for equipping the operating forces so they can accomplish their warfighting mission. Marine Corps Systems Command plans and manages research, development, and acquisition programs through equipment production and fielding for employment by MAGTF forces, including most equipment programs that support GEOINT.

Marine Corps Intelligence Activity

The MCIA is the Marine Corps' Service intelligence production center. In addition, the MCIA supports other Services and government organizations as appropriate. It provides the Marine Corps with intelligence for planning, training, operations, systems development, and exercises. The MCIA can be tasked to provide expeditionary warfare intelligence to support any national, theater, or operational command in the US Armed Forces. The MCIA's analysis and production supports not only the Marine Corps, but also national decisionmakers, theater commanders, and tactical warfighters.

National Geospatial-Intelligence Agency Support Teams

The NGA provides support teams to the Marine Corps with a specific mission, organization, and responsibilities.

National Geospatial-Intelligence Agency Support Team Mission. The NST representatives train and work with the MEF, MSCs, and other intelligence personnel to integrate IMINT and GI&S and future National System for Geospatial Intelligence (NSG) capabilities into MEF operations. The NSTs also evaluate the use of IMINT and GI&S and NSG concepts and products supporting the MAGTF mission.

National Geospatial-Intelligence Agency Support Team Organization. The NSTs are collocated with supported Marine Corp units and are an extension of both the NST-Marine Corps and the NGA staff officer. The NSTs provide direct access to the NGA geospatial libraries and support interoperability between the Marine Corps and the NGA. The NSTs execute all tasks in coordination with guidance provided by NST-Marine Corps, the NGA staff officer, and the MEF GEOINT chief.

National Geospatial-Intelligence Agency Support Team Responsibilities. The responsibilities of the NST include the following:

- Serving as the focal point for NGA GEOINT activity within each MEF and assisting each MEF with identifying IMINT and GI&S requirements.
- Installing and maintaining NGA application software and new NGA prototype systems and products as they become available and familiarizing imagery personnel with the software applications.
- Training IIP and MEF intelligence personnel to use NGA data and applications for planning and integration into organizational systems.
- Developing, maintaining, and presenting demonstrations of current and projected GEOINT capabilities.
- Evaluating GEOINT software and data, reporting findings to NST-Marine Corps, the NGA staff officer, HQMC-IPI, MEFs, intelligence battalions, and topographic platoons.
- Coordinating actions affecting MAGTFs with NST-Marine Corps, the NGA staff officer, HQMC-IPI, MEFs, intelligence battalions, and IIPs.
- Providing technical support for NGA products used in MAGTF systems.
- Assisting with developing tactics, techniques, and procedures (TTP) to support the rapid generation of new data and/or intensification of existing data sets.

- Assisting with technical reviews of developmental data sets, products, systems, and associated documents to ensure standard NGA data are used and new GEOINT product requirements are promptly identified.
- Assisting the imagery analysts with the technical use of NGA and NSG products.
- Assisting with the integration of the NGA's NSG concept into existing MAGTF architectures and migration plans.

CHAPTER 3
MAGTF IMAGERY INTELLIGENCE UNITS AND ORGANIZATIONS

This chapter describes the missions, tasks, organization, and CONOPS for Marine Corps units responsible for conducting tactical IMINT.

IMAGERY INTELLIGENCE PLATOON INTELLIGENCE BATTALION

The IIP is responsible for certain missions and tasks; it is organized to provide IMINT to supported units and has a specified command and control relationship and a concept of employment.

Mission and Tasks

The mission of the IIP is to provide IMINT support to MAGTFs and other commands, as directed. Specific IIP tasks include—

- Exploiting and analyzing all-source, multisensor imagery to derive intelligence pertaining to installations, troop dispositions, strengths, and activities of various conventional and nonconventional forces.
- Planning for and tasking multisensor platforms, including both those that are organic to and those that are external to the MAGTF.
- Conducting imagery exploitation and data management.
- Providing imagery derived products and reports to the MEF commander and other commanders.
- Conducting liaison with the Service-level intelligence center and external agencies for obtaining imagery products in support of MEF intelligence requirements.

Organization

An IIP is organic to each MEF and is subordinate to the P&A company of the intelligence battalion. Each IIP has a platoon headquarters, two tactical imagery analysis sections, and three imagery analysis teams (see fig. 3-1 on page 3-2).

In 2006, the 4th Imagery Interpretation Unit was incorporated into Company B, Intelligence Support Battalion of United States Marine Corps Forces Reserve (MARFORRES) and redesignated as an IIP. The 4th IIP is organized into one headquarters section, two tactical imagery analysis sections, and three imagery analysis teams. Reserve imagery analysts are also assigned to the AFP geospatial production detachment. During regular Reserve drills, the imagery analysts of

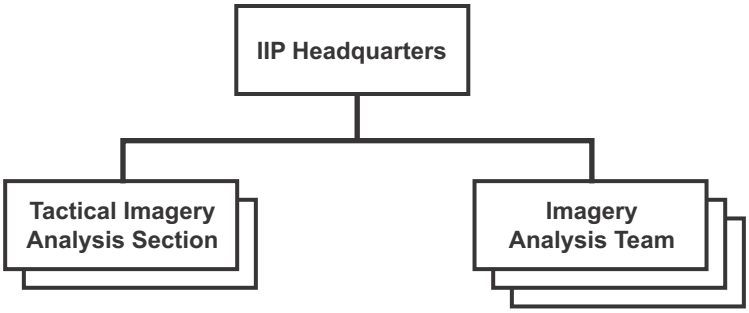

Figure 3-1. Imagery Intelligence Platoon Structure.

the IIP and geospatial intelligence directorate participate in federated imagery production in support of the MCIA. They also frequently perform active duty operational support to the operating forces and the national intelligence community. Reserve imagery analysts may also be mobilized as units, in teams, or as individual augments in support of operations and exercises.

Command and Control

The intelligence battalion commander is in charge of command and control of the IIP, while the MEF staff has cognizance over their activities. The platoon also has other support relationships with various units.

Intelligence Battalion Commander. The IIP is a subordinate unit of the intelligence battalion and the intelligence battalion commander retains full command of its operations. When supporting smaller MAGTFs, the IIP (or its detachments) will operate under the command and control of either the intelligence detachment OIC or the supported unit's G-2/S-2.

Marine Expeditionary Force Staff Cognizance. The MEF commander exercises command and control over all intelligence battalion elements, including the IIP, via the MEF AC/S G-2 systems officer. The systems officer directs the integration of IIP operations with other MEF IMINT operations.

Support Relationships. The IIP operates in general support of the MEF. Under this command relationship, the MEF commander, in consultation with both the AC/S G-2 and the ISC, determines priorities for intelligence collections and production support, locations of IMINT support nodes, and the means for IMINT and all-source intelligence dissemination.

The IIP, or task-organized imagery analysis detachments, may be employed in direct support of, or attached to, a particular MSC or unit of the MEF, based upon mission, enemy, terrain and weather, troops and support available-time available (METT-T) considerations. In these cases the scope of the supported commander's C2 authority over assigned IIP elements will be specified to ensure effective support to operations while allowing the MEF commander to maintain effective command and control of broader intelligence and IMINT operations. Direct support or attachment relationships may consist of dedicated imagery exploitation support, placement of IIP assets with the supported unit, or simply establishing an IMINT node at the supported unit to provide direct dissemination of imagery and IMINT to the intelligence section or COC. In the latter of these relationships, an IIP liaison element should be provided to the supported unit. Generally,

continuing relationships between IMINT elements and supported units should be established whenever possible.

Concept of Employment

An IIP supports each MEF. Task-organized imagery analysis detachments may be attached to MAGTF command elements, either independently or as part of a larger intelligence battalion detachment, when supporting a Marine expeditionary brigade, Marine expeditionary unit (MEU), or other special purpose MAGTF, as the mission requires.

The Reserve IIP conducts peacetime training and production activities in garrison at Buckley Air National Guard Base, Aurora, Colorado. The IIP and geospatial intelligence directorate of the AFP participate in federated imagery production in support of MARFORRES units, the MCIA, or the CCMDs during regularly scheduled reserve drill periods. The Reserve IIP also provides services and task-organized detachments of intelligence personnel to augment active component elements, joint commands, and national agencies in peacetime, times of crisis, contingency, or war.

The Marine imagery analysis specialists' primary imagery exploitation system is the tactical exploitation group (TEG) (see fig. 3-2 on page 3-4). The modular and scalable TEG employs commercial off-the-shelf, government off-the-shelf, and nondevelopmental item computer hardware and software to enable rapid upgrades and maintain commonality and interoperability with other Marine Corps and joint intelligence and imagery systems. The TEG provides the MAGTF commander with an organic capability to produce IMINT products in support of all operations. The TEG provides the capability to data-link imagery from theater and tactical assets as well as resourcing repositories via classified networks to support tailored imagery analysis. The TEG also disseminates imagery products and imagery exploitation reports to the MAGTF commander and subordinate commanders in support of tactical operations, strike planning, detection and location of targets of opportunity, and combat damage assessment for restrike planning and intelligence assessment. Anticipated upgrades will enable the processing of imagery from additional manned and unmanned platforms, improve video capture and exploitation capabilities, enhance net-centric functionality, and increase modularity. The TEG has two echelon-tailored configurations: virtual imagery processing-Marine Corps (VIP-MC) and tactical exploitation group-remote workstation (TEG-RWS).

The VIP-MC is the IMINT ground station for the MEF. Each IIP in the operating force has one VIP-MC; there is no VIP-MC dedicated to MARFORRES. The TEG-RWS is the deployable IMINT workstation for deploying units of the MEF. Imagery analysts of intelligence support battalion, MARFORRES maintain a limited deployable TEG-RWS capability.

Miscellaneous

Other miscellaneous items relating to IIP's operations are communications and information systems and the maintenance concept for their equipment.

Communications and Information Systems. The IIP requires a significant amount of communication resources to support internal and detachment C2 requirements. Additionally, the IIP needs access to various classified networks to conduct its operations.

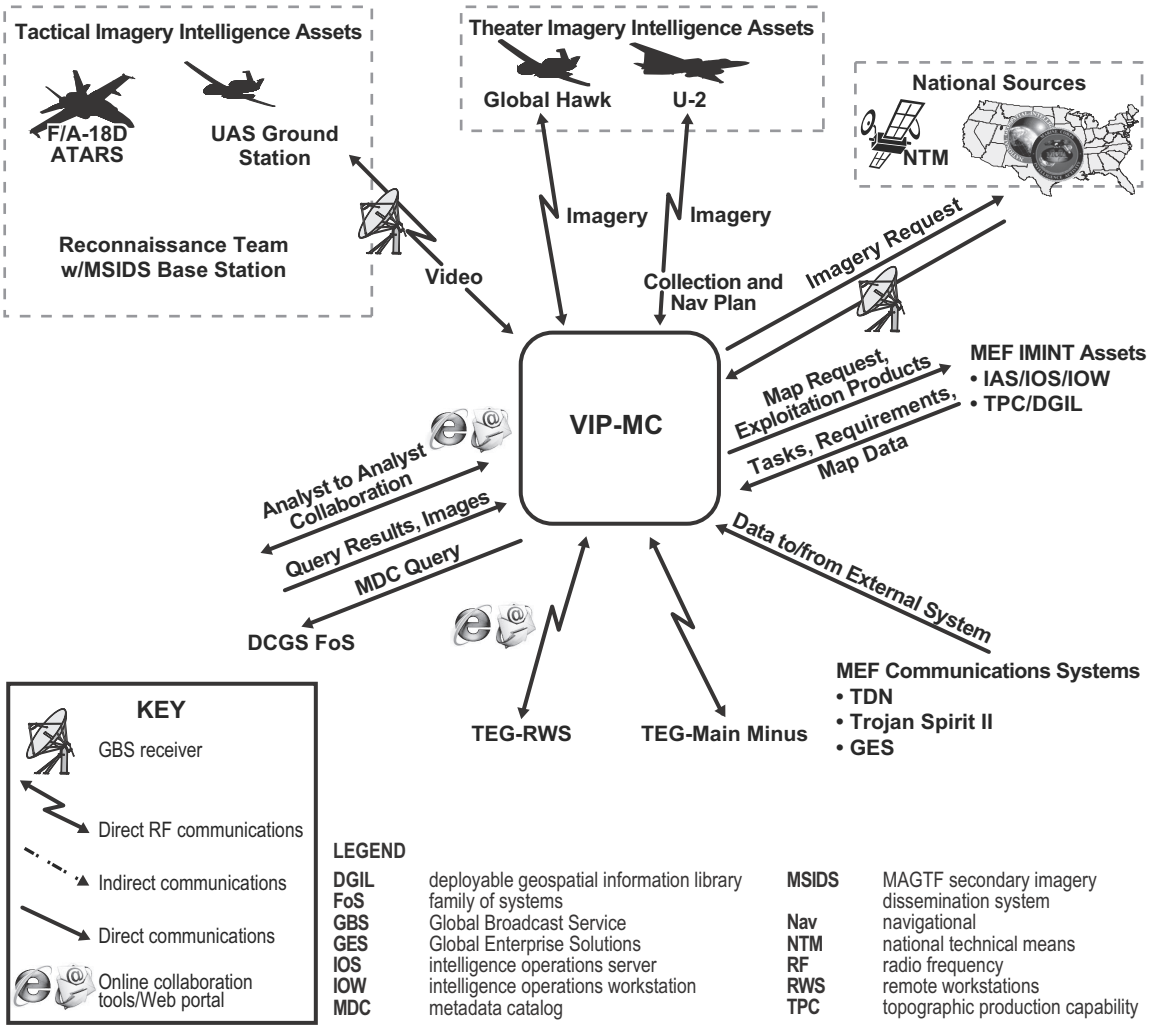

Figure 3-2. Virtual Imagery Processing-Marine Corps.

Maintenance Concept. The chosen product support strategy is to use contractor logistics support (CLS) supply chain management and field support representatives (FSRs) and to use the lead systems integrator (LSI) to track warranties, establish maintenance contracts, and provide software support solutions as well as to perform technology refreshes.

The TEG family of systems (FoS) is supported by the two-level maintenance concept (field and depot) per Marine Corps Order (MCO) 4790.25, *Ground Equipment Maintenance Program*. Tactical exploitation group FoS field level maintenance is performed using standard Marine Corps operating procedures and organic personnel. The Marine-performed maintenance is supported by program manager office-shared FSRs that are currently supporting the fielded TEG-RWS via a LSI contract. Equipment requiring depot level maintenance is evacuated to CLS personnel. Depot level software maintenance is performed by the LSIs. Depot level hardware maintenance is performed by the original equipment manufacturer.

With respect to unit-level maintenance, each intelligence battalion is responsible for organizational-level preventive maintenance on the TEG FoS and all associated organic Marine Corps equipment based on the unit's table of organization.

The MARCORSYSCOM TEG program office is responsible for the budgeting and funding of the CLS contract for the entire life cycle of the TEG FoS. The TEG FoS is supported by the two-level maintenance concept (field and depot) per MCO 4790.25, *Ground Equipment Maintenance Program.*

Regarding transportation, the intelligence battalion has limited organic rolling stock to support IIP operations. External transportation support from the Marine expeditionary force headquarters groups, the MLG/supported unit is needed to move all parts of the IIP simultaneously.

TACTICAL ANALYSIS AND COMBAT TRACKING EXPLOITATION TEAM, INTELLIGENCE BATTALION

The tactical analysis and combat tracking exploitation (TACTEX) team is responsible for certain missions and tasks. It is organized to provide the moving target indicator (MTI) capability to supported units, has a specified C2 relationship, and has its own concept of employment. The duties of the TACTEX team may be performed by an imagery analysis specialist (military occupational specialty [MOS] 0241) or by an intelligence analyst (MOS 0231). An MTI is a graphical representation of moving objects on the Earth's surface. These objects are detected by radar through Doppler shift. The radar detects moving vehicles, surface vessels, rotating antennas, slow-moving aircraft, and smaller targets (such as personnel).

Mission and Tasks

The TACTEX team provides the MEF with near real time (NRT) and forensic access in order to receive, process, exploit, and analyze multiple levels of MTI, fixed target indicator (FTI), SAR imagery, high range resolution data, UAS video data, and SIGINT/communications intelligence data via the integrated broadcast service from any MTI collection platforms. Specific TACTEX tasks, performed by MOS(s) 0241 and 0231 include—

- Receiving, processing, manipulating, storing, and displaying NRT MTI, FTI, and SAR data from MTI sensors simultaneously.
- Disseminating MTI data and textual analysis to the MEF AC/S G-2, other elements of the MEF, and other forces, as directed.
- Assisting with the planning and directing of MTI collection operations in support of the MEF.
- Retrieval of historical MTI data from local databases or mission archive services to conduct forensics analysis. An MTI forensics analysis involves analyzing MTI data within specified parameters (time, location, size, speed) that is correlated with other intelligence data to add context and meaning, and produce actionable intelligence.
- Providing the capability to communicate, via voice and/or digital link, with a variety of the MTI platforms, including but not limited to the E-8 Joint Surveillance Target Attack Radar System (JSTARS), the P3 Orion Littoral Surveillance Radar System (LSRS), the Sentinel's Airborne Standoff Radar, the Sea King Mk7 Airborne Surveillance and Control helicopter, and the vehicle dismount and exploitation radar (VADER) platform.

Organization

A TACTEX team is organic to each MEF and is currently located at the corresponding intelligence battalion. Cell structures within the battalions vary. For example, the 1st Intelligence Battalion maintains its cell under collections and the 2d Intelligence Battalion maintains its cell under the IIP. Regardless of the cell structures, however, teams will be moved to the battlefield surveillance company when they are formed, in accordance with the MCISR-E roadmap.

Each MEF has one JSTARS antenna suite (JAS) (comprised of a transit cased surveillance control data link [SCDL] ground data terminal [GDT] and SATCOM suite) and tactical exploitation group–remote workstations (TEG-RWS) variant integrated with the VANTAGE™ Ascent Software (VAS) and MOVINT Client (MC) exploitation software. Together the JAS and TEG-RWS, form the Moving Target Indicator Operation Suite (MTI OS). The MTI OS will be used to source all MAGTF MTI analysis requirements.

Command and Control

The TACTEX team operates in general support of the MEF. The intelligence battalion commander, as the ISC, retains full control of TACTEX team activities. The MEF commander exercises command and control over intelligence battalion elements via the MAGTF intelligence officer, including the TACTEX MTI OS, which is a scalable, expeditionary/rapid-deployment capability.

Concept of Employment

The majority of MTI platforms are national assets that support either a JTF joint force land component commander or a ground component commander under the overall direction of the JFC.

Once the TACTEX team receives data at the MTI OS from the MTI collection platform, the MTI analyst develops a report and/or MTI product that can be disseminated throughout the MEF according to the intelligence reporting criteria directed by the MAGTF intelligence officer. Under routine conditions, these data are disseminated to the P&A cell for follow-on analysis and fusion with other intelligence data to produce all-source intelligence products.

The METT-T factors may require that E-8C data be provided to other elements of the MEF and subject data be disseminated to subordinate units via the MEF tactical data network (TDN). The MTI/FTI/SAR image, with its associated data, will be viewed by recipients (potentially down to and including the regimental/group level) using common Marine Corps hardware and software suites.

Equipment. The TACTEX team's equipment is discussed in the following subparagraphs.

Moving Target Indicator Operation Suite (MTI OS). The MTI OS consists of the JAS and any TEG-RWS variant. The JAS contains a transit cased SCDL GDT, SCDL Masthead and supplementary gear, and the SATCOM Suite, comprised of a PSC-5D SATCOM radio, ancillary gear and antennas. The JAS provides a direct data link to the JSTARS E-8C for receipt of near-real-time (NRT) MTI data, fixed target indicators (FTI) and SAR imagery.

When connected to the SIPRNET, the MTI OS can access MTI from other MTI collection platform ground stations and online MTI databases such as mission archive services and

real-time dissemination and online transmission services. The mission archive services is a Web-accessible environment that provides a data enterprise to store, retrieve, and share archived MTI data and related information. Real-time dissemination and online transmission services' primary function is to provide dissemination of current MTI data.

Each TEG-RWS variant has the VAS and MC exploitation software. The VAS has a JSTARS interface, where the MTI operator can configure the SCDL and SATCOM suite hardware, and submit radar service requests and exchange free text messages. The MC is used to exploit the MTI and fuse the MTI data with other intelligence products.

Intelligence, Surveillance, and Reconnaissance Forensic Analysis System. The ISR Forensic Analysis Systems are Windows-based operating systems capable of providing NRT support to the MTI effort by means of SECRET Internet Protocol Router Network (SIPRNET)-data streaming. These systems are also optimal for providing detailed forensic analysis of historical data. Though not limited strictly to these functions, forensic analysis missions generally focus on studies of the following types: line of communications (LOC), traffic pattern analysis, counter-improvised explosive device backtrackings, high-value individual and high-value target, pattern of life, border crossing, littoral and maritime, cache site, traffic density, and density plot and analysis. Intelligence, surveillance, and reconnaissance forensic analysis systems are not organic program of record assets to a TACTEX team and, as a result, must be maintained as additional/ supplemental CIS resources provided internally by the MEF communication battalions.

Miscellaneous

Miscellaneous issues that affect TACTEX units are communications and information systems, maintenance, and transportation issues.

Communications and Information Systems. The MTI OS has no organic communication resources, but when communications and information systems (CIS) resources are made available the MTI operator can support internal command and control, operations, and intelligence requirements, as well as external communications with MTI platforms and ground stations. Typically, the MTI OS will require access to the SIPRNET and pertinent local area networks (LANs) and wide-area networks (WANs). The TACTEX team members can operate all organic CIS equipment; however, all CIS resources must be provided by the MEF communications battalion.

Maintenance. As part of the TEG FoS, the MTI OS is supported by the two-level maintenance concept (field and depot) per MCO 4790.25, *Ground Equipment Maintenance Program*. The TEG FoS field level maintenance is performed using standard Marine Corps operating procedures and organic personnel. The Marine-performed maintenance is supported by program manager office-shared FSRs that are currently supporting the fielded TEG-RWS via an LSI contract. Equipment requiring depot level maintenance is evacuated to CLS personnel. Depot level software maintenance is performed by the LSIs. Depot level hardware maintenance is performed by the original equipment manufacturer.

Transportation. The TACTEX team has sufficient resources to displace all MTI OS equipment. Additional sup-port will be needed from the MEF headquarters group or the MLG to displace common ground station and joint Services workstation personnel simultaneously.

MARINE UNMANNED AERIAL VEHICLE SQUADRON

The VMU is responsible for certain missions and tasks. It is organized to support the MEF, has a specified command and control relationship, and a concept of employment.

Mission and Tasks

The mission of the VMU is to operate and maintain UASs that support the MEF/other supported units. Specific VMU tasks include the following:

- Conducting aerial reconnaissance (including imagery collection and reporting), surveillance (including airborne surveillance of designated target areas, MEF or other areas of interest, and other areas, as directed), and target acquisition.
- Conducting airborne surveillance for search and rescue and tactical recovery of aircraft and personnel.
- Conducting reconnaissance of helicopter approach and retirement lanes in supporting vertical assaults.
- Providing real-time target information to the direct air support center (DASC) and fire support coordination center(s) (FSCCs) to facilitate adjusting fire missions and close air support.
- Providing real-time intelligence reporting to the SARC to support MEF intelligence requirements and to facilitate all-source intelligence operations.
- Providing information to assist adjusting indirect-fire weapons and to support and facilitate direct air support and air interdiction operations.
- Providing remote receive capability and liaison to designated units.
- Collecting information to support BDA and combat assessment.
- Supporting rear area security.

Organization

The VMU has an external and an internal organization.

External Organization. The VMU is organic to the MAW and is structured to operate as a subordinate unit of one of the Marine air control groups (MACGs).

Internal Organization. Each of the three active component VMUs can be organized into 12 self-contained detachments: three RQ-7B SHADOW UAS suites and nine RQ-21A BLACKJACK UAS suites. Each detachment can operate and maintain one UAS suite. The RQ-7B SHADOW UAS suite is comprised of four air vehicles, two ground control stations, one launcher, and associated recovery gear. The RQ-21A BLACKJACK UAS suite is comprised of five air vehicles, two ground control stations, one launcher, and one recover device.

Command and Control

The VMU is under the command of the MAW commanding general or the aviation combat element (ACE) MAGTF commander (when deployed in support of MAGTFs smaller than a MEF). The supported commander exercises command and control via the ACE G-3/S-3 and the Marine air command and control system (MACCS) (see Marine Corps Warfighting

Publication [MCWP] 3-25, *Control of Aircraft and Missiles*). Air operations (e.g., flight tasking, airspace deconfliction) are planned, coordinated, and controlled by the ACE G-3/S-3 via the Marine tactical air command center (TACC). However, intelligence missions are tasked per the intelligence and reconnaissance mission requirements designated by the MEF or supported unit commander; this action requires close coordination between the intelligence battalion IOC and the MAW Marine TACC.

Normally, a VMU operates in general support of a MEF. The MEF commander, through the AC/S G-2, determines VMU intelligence priorities and information and intelligence dissemination flow when the VMU is operating in the general support role. The AC/S G-2 will exercise staff cognizance of VMU intelligence operations via the ISC.

Marine unmanned aerial vehicle squadron missions may be flown in direct support of particular MEF units or MSCs (e.g., the Marine division or its main effort). In these cases, the scope of the supported commander's C2 authority over VMU missions should be specified to ensure effective support to the operations while allowing the MAGTF commander to maintain effective command and control of broader intelligence and IMINT operations. Direct support missions may require that dedicated command and control, planning, and exploitation be provided to the supported unit via a VMU detachment.

Concept of Employment

A VMU can support any size MAGTF; however, normal employment would be as an integral unit of the MAGTF's ACE. The VMU can also conduct limited independent operations.

The VMU's intelligence section consists of 2 officers, 10 intelligence specialists (MOS 0231), and 38 imagery analysis specialists (MOS 0241). The intelligence section is responsible for planning collections, collecting IMINT, producing and disseminating imagery reports, imagery products, and all-source intelligence analysis.

The VMU can conduct limited imagery exploitation/analysis. Generally, UAS imagery is screened by VMU imagery analysts for information of immediate tactical value per the intelligence collection and reporting criteria stipulated by the ISC or the supported unit's intelligence officer. In most cases, the information and imagery products are sent directly to the supported unit. Imagery is also disseminated by VMU to the IIP for further detailed imagery analysis and all-source intelligence production. The MAGTF intelligence officer is responsible for subsequent IMINT dissemination, including secondary imagery dissemination.

Miscellaneous

The miscellaneous issues that affect the VMU are communications and information systems, maintenance, and equipment.

Communications and Information Systems. Each VMU has sufficient CIS resources, which include those associated with the MACCS, to support internal and squadron command and control, operations, and intelligence requirements. The VMU normally needs access to Nonsecure Internet Protocol Router Network (NIPRNET), SIPRNET, and pertinent LANs and WANs.

Maintenance. Each VMU can perform organizational maintenance on its aviation equipment. The squadron can also perform first echelon maintenance on assigned ground equipment, including motor transport, engineering, and communications equipment. The MLG or supporting combat logistics battalion performs third and fourth echelon maintenance on ground equipment.

Equipment. See appendix G for VMU equipment and performance characteristics.

MARINE FIGHTER/ATTACK (ALL-WEATHER) SQUADRON

Mission and Tasks

The mission of the VMFA(AW) is to attack and destroy surface targets, day or night, under adverse weather conditions; conduct multisensor imagery reconnaissance; provide supporting arms coordination; and intercept and destroy enemy aircraft under all weather conditions. Specific VMFA(AW) tasks include the following:

- Conducting airborne surveillance for search and rescue and the tactical recovery of aircraft and personnel.
- Conducting day and night close air support under all weather conditions.
- Conducting day and night deep air support under adverse weather conditions (e.g., armed reconnaissance, radar search and attack, air interdiction, and strikes against enemy installations) using all weapons that are compatible with the aircraft.
- Conducting multisensor imagery reconnaissance (e.g., pre-strike and post-strike target damage assessment and visual reconnaissance).
- Conducting day and night supporting arms coordination (e.g., forward air control, tactical air coordination, and artillery/naval gunfire spotting).
- Intercepting and destroying enemy aircraft in conjunction with ground and airborne fighter direction.
- Conducting battlespace and target illumination.
- Conducting armed escorts of friendly aircraft.
- Conducting the suppression of enemy air defense operations.

Organization

There are five F/A-18D VMFA(AW)s in the operating forces. Each squadron has 12 aircraft; only three to four aircraft are configured with the advanced tactical airborne reconnaissance system (ATARS) at any one time. The VMFA(AW) normally functions as a unit: it is structured to operate as a subordinate unit of a Marine aircraft group in support of the MAGTF. Key squadron intelligence personnel include the S-2, two all-source intelligence analysts, and four imagery analysts.

Command and Control

Each VMFA(AW) falls under the command of its parent group commander. Overall, depending on the configuration of the MAGTF, operational control rests with the MAW or ACE commander. The commander exercises command and control via the ACE G-3/S-3 and the MACCS (see MCWP 3-25 for more information). Air operations (e.g., flight tasking, airspace deconfliction) are planned, coordinated, and controlled by the G-3/S-3 via the Marine TACC. However, intelligence missions are conducted according to the mission requirements designated by the MAGTF or supported unit commander and require close coordination among the intelligence battalion IOC, the Marine TACC, and supported commanders.

Marine fighter/attack (all weather) squadrons typically operate in support of the MAGTF as assigned in the ATO. However, their VMFA(AW) missions may be in direct support of a particular unit of the MAGTF (i.e., ground component, the ACE, or logistics combat element [LCE]) based on METT-T considerations. The ATO will identify these missions, pertinent command and control, and intelligence operations direction.

Concept of Employment

The VMFA(AW)'s concept of employment should be considered in terms of operations and intelligence. When viewed in operational terms, the VMFA(AW) is normally employed as a unit of an ACE in support of MAGTF operations. With respect to intelligence, the VMFA(AW), when equipped with ATARS and tasked to conduct imagery collection missions, coordinates operations closely with the IOC, the MAW AC/S G-2, the IIP, and others as appropriate.

The processing of ATARS imagery is completed on the VMFA(AW), utilizing the TEG-RWS. Each VMFA(AW) is equipped with a TEG-RWS and has the capability to exploit and produce imagery as well as IMINT products and reports in support of requirements. The ATARS imagery is screened by VMFA(AW) imagery analysts for information of immediate tactical value according to intelligence collection and reporting criteria. Exploited imagery from the VMFA(AW) may be hosted on a designated imagery server. Each VMFA(AW) can conduct limited imagery exploitation or analysis. Each VMFA(AW) is interoperable with the VIP-MC, providing NRT downlinking of selected images; the remaining imagery data will be processed with the TEG-RWS. It may also be disseminated to the IIP for additional imagery exploitation support. Figure 3-3, on page 3-12, provides an overview of VMFA(AW) ATARS imagery processing flow.

Miscellaneous

Each VMFA(AW) has sufficient CIS resources to support internal and squadron command and control, operations, and intelligence requirements. The VMFA(AW) needs access to various networks to conduct its operations, including NIPRNET and SIPRNET as well as other pertinent LANs and WANs.

The VMFA(AW) can conduct first echelon maintenance on all assigned equipment. It can also perform organizational maintenance on assigned aircraft and support equipment. Maintenance requirements that exceed these capabilities are provided by other ACEs and LCEs.

Each VMFA(AW) can fulfill its own particular administrative requirements.

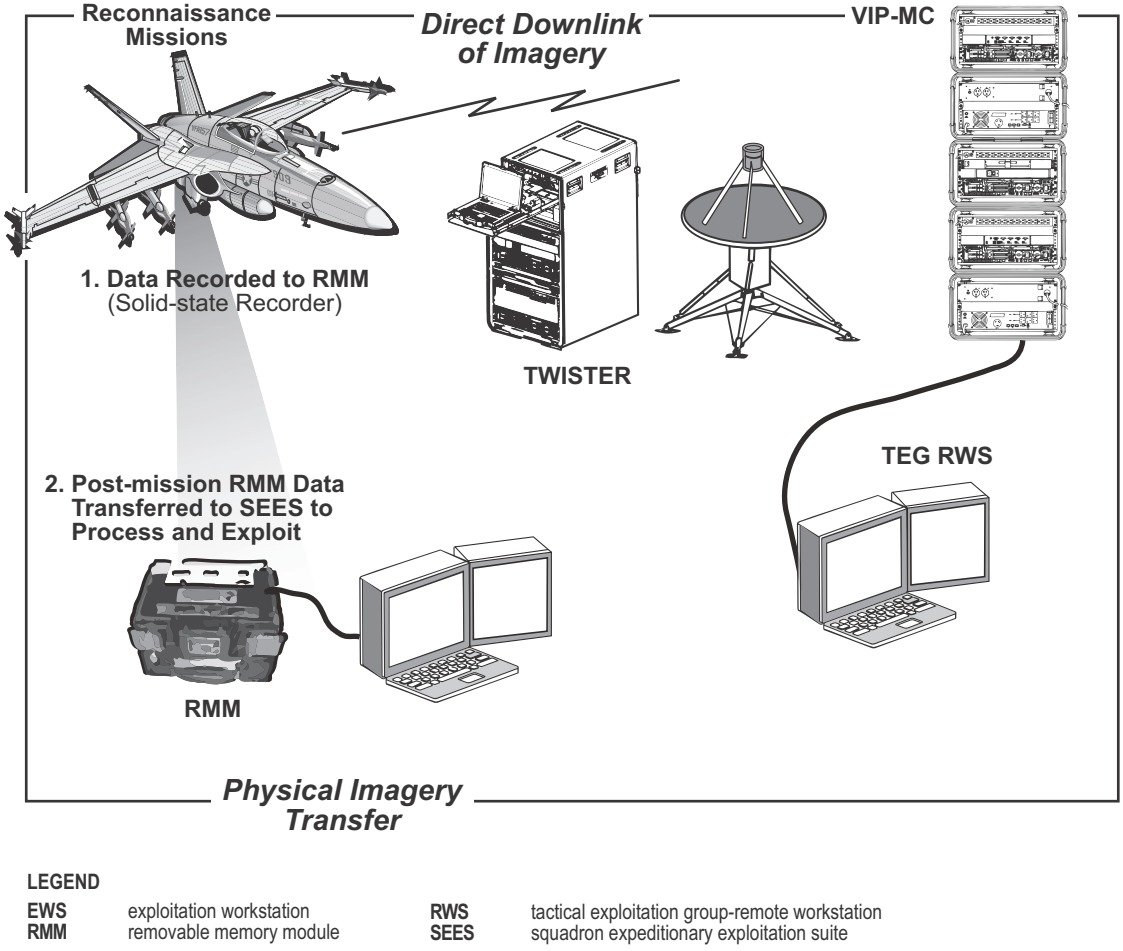

Figure 3-3. An F/A-18 Advanced Tactical Airborne Reconnaissance System Tactical Reconnaissance Imagery Processing Flow.

GROUND RECONNAISSANCE

Mission

The force reconnaissance company and the division reconnaissance battalion provide amphibious, deep ground, and ground reconnaissance; surveillance; battlespace shaping; and limited-scale raids in support of the Marine division, its subordinate elements, the MEF, other MAGTFs, or a joint force. The IMINT capability fielded to these units is the MAGTF secondary imagery dissemination system (SIDS).

Organization

There are three Active Component and one Reserve Component reconnaissance battalions. A standard reconnaissance platoon within a battalion consists of a headquarters section and three six-man reconnaissance teams.

Command and Control

The force reconnaissance company and the division reconnaissance battalion are under the operational control of the supported unit's commander. For intelligence and reconnaissance missions, the commander exercises command and control over ground reconnaissance via the unit's intelligence officer. At the MEF level, the AC/S G-2 exercises this staff cognizance via the ISC. This structure allows for the centralized direction and effective integration of ground reconnaissance operations with the broader all-source intelligence CONOPS.

Ground reconnaissance units normally operate in a general support relationship to supported units. Depending upon tactical considerations, ground reconnaissance units may be employed in direct support of, or attached to, particular subordinate units (e.g., force reconnaissance teams attached to advance force elements for an expeditionary operation; division reconnaissance battalion's platoons; or teams attached to, or in direct support of, the division's main effort). To ensure effective support to the operations while allowing the MEF or division commander to maintain effective command and control of broader intelligence and reconnaissance operations, the scope of the supported commander's C2 authority over designated ground reconnaissance teams is usually specified.

Concept of Employment

The force reconnaissance company normally operates under the staff cognizance of the MAGTF G-2/S-2 for reconnaissance and surveillance missions and under the staff cognizance of the MAGTF G-3/S-3 for offensive missions. The basic operating unit is the team; however, platoons or task-organized elements may be employed to accomplish certain tasks.

Force reconnaissance operations should have a defined scope and duration, with planned exfiltration. Teams are usually inserted into the supported commander's area of interest (AOI) (usually the deep area), often well beyond the supporting arms and reserve elements of the enemy's committed forces, in order to collect and report information in response to the commander's PIRs.

When required by the situation, the company or detachments may be placed in direct support of, or attached to, smaller MAGTFs or to MEF elements other than the command element. Normally, a force reconnaissance detachment is attached to a MEU.

Because force reconnaissance company units routinely operate beyond the range of the MAGTF's supporting arms, the company must maintain the capability to clandestinely insert and extract units over extended distances. Such means include foot movement, surface or subsurface swimming, vehicles, rotary- or fixed-wing aircraft, small boats, landing craft, and commercial assets. All teams are capable of using closed-circuit underwater breathing apparatuses, open-circuit SCUBAs [self-contained underwater breathing apparatuses], and submarine lock-outs. Also, all teams are capable of static-line and military free-fall parachuting.

Deployed teams use standard techniques of small-unit scouting and individual movement. Unless the mission requires otherwise, force reconnaissance teams will avoid contact with the enemy or indigenous people. Teams either observe from vantage points or physically reconnoiter the AOIs. As directed, teams report by radio and/or during post mission debriefings. When conducting offensive operations, force reconnaissance company elements employ the previously described

techniques to reach their objective sites. Conducting actions at the objective area, they employ close-quarter battle, standard tactical assault, or sniper techniques to neutralize or destroy enemy targets and/or to recover designated personnel or materiel.

Teams assigned to initial terminal guidance missions reconnoiter the landing area and provide last-minute visual or electronic terminal guidance to flight, wave, or stick leaders. Initial terminal guidance missions terminate with the arrival of the helicopter support team, US Navy beach party, landing craft air cushion LZ control teams, US Army Pathfinder teams, or US Air Force combat control teams, which then assume traffic-control functions.

CHAPTER 4
IMAGERY INTELLIGENCE SYSTEMS, C2 NODES, CIS, AND OTHER SYSTEMS

This chapter addresses the major MAGTF IMINT C2 and CIS nodes from a systems perspective and describes the impacts of processing, exploitation, and dissemination on these nodes.

BASIC IMAGERY INTELLIGENCE COMMUNICATIONS AND INFORMATION SYSTEMS REQUIREMENTS

Managing Subordinate Imagery Intelligence Units

Intelligence officers and IMINT element OICs must maintain positive command and control of subordinate units and integrate their operations with broader MAGTF and external intelligence and operational command and control. Traditionally, single-channel radio and recorded message traffic has been used to support command and control of MAGTF IMINT elements. In semi-static situations, secure e-mail or telephone may be the method of choice for communicating; whereas, in highly fluid or mobile scenarios, cellular telephones, SATCOM, and radio may be used.

Receiving Data and Information From Organic/External Imagery Intelligence Organizations

Communication and information systems architecture must provide connectivity between organic and supporting IMINT elements, IMINT production and analysis centers, and supported MAGTF operations and intelligence centers. Requirements include the ability to transmit images and related data files and IMINT reports digitally via fiber optics, wire/radio in both voice and data formats that are readily usable by imagery and all-source intelligence analysts.

Providing Intelligence to Supported Commanders

Imagery intelligence CIS requirements are influenced by the supported commanders' intent, CONOPS and intelligence, command relationships, and standing PIRs and intelligence requirements. Communication and information systems architecture must be capable of integrating IMINT element command and control and supporting CIS operations with the primary CIS channels used by the supported commanders.

Providing Imagery Intelligence Products and Reports to National Intelligence Centers, Theater, Joint Task Force, MAGTF, and Other Components

Imagery intelligence products are provided to designated organizations via the MAGTF's organic secured/nonsecured communications networks.

IMAGERY INTELLIGENCE AND RELATED COMMAND AND CONTROL NODES

The national nodes for imagery intelligence, NST, and NRO were discussed in chapter 2.

Within a theater, there are different levels of nodes, such as the combatant commander JIOC, the JTF J-2, and the JISE.

Combatant Commander Joint Intelligence Operation Center

The combatant commander, JIOC is responsible for fulfilling the intelligence requirements of both the combatant commander and his subordinate commanders. By providing finished intelligence products supporting theater mission planning and execution, the JIOCs are the primary sources from which subordinate JTFs receive intelligence support for their AOI.

Collection. Combatant commander J-2s retain full collection management authority over all ICRs against targets within their area of responsibility. This authority may be delegated to a subordinate JFC. Validated collection requirements that cannot be satisfied by organic means, including imagery collection, are submitted to the CCMD JIOC.

Processing and Exploitation. Each JIOC processes and exploits imagery in its particular theater. Downlinked imagery data signals may be transmitted to workstations for immediate exploitation/archiving.

Production.Combatant command and Service Intelligence Center production responsibilities are clearly delineated within the Department of Defense Intelligence Production Program (DODIPP). The DODIPP is structured to capitalize on the analytical and production resources of the entire DOD intelligence production community. The community on-line intelligence system for end-users and managers automates DODIPP procedures for stating and tracking theater intelligence requirements and other intelligence production requirements. Results from imagery exploitation and the annotated images may be incorporated into all-source intelligence products, standalone IMINT products, or into various GEOINT databases.

Dissemination. Dissemination of digital products is done via the DCGS-MC and the primary dissemination medium for intelligence is SIPRNET. Along with e-mail distribution, the JIOC utilizes Web sites and portals as hubs to collaborate and post finished intelligence products.

Joint Task Force J-2 and the Joint Intelligence Support Element

The JTF J-2 organizational structure and capabilities are driven by the mission. Intelligence CIS, based on functionality, enables the JTF to query theater and national IMINT servers and databases for current intelligence.

The JISE is the principal intelligence C2 node within the JTF J-2 and is the focus for JTF intelligence operations, providing the JFC and component commander with situational awareness and other intelligence support regarding adversary air, ground, maritime, and space capabilities and activities. A NIST, supporting the JTF headquarters, integrates its operations within the JISE. Key JISE functions and capabilities include collection management support, OOB analysis,

identification of threat critical capabilities (i.e., critical requirements), critical vulnerabilities, and intelligence support to targeting and force protection.

All IMINT collection, production, and dissemination activities are conducted within the JISE. Once IMINT products and support have been provided to the JTF and its components, updates are delivered by the JISE using multiple dissemination techniques.

Collection. The JTF J-2 collection manager plans, coordinates, and employs direct imagery collection operations to support the JTF. The MAGTF interfaces with the collection assets, as is depicted in figure 3-2, on page 3-4. Communication support planning provides connectivity from these major nodes into the TEG and MAGTF TDN.

Production. Imagery intelligence production requirements are managed by the JISE per the JFC's PIRs and validated intelligence requirements.

Dissemination. Once basic and current intelligence and imagery have been provided to a deploying JTF and its components, updates will be accomplished using multiple dissemination techniques. Intelligence CIS, based on the applicable networks, provides the JTF with the ability to query theater and national IMINT servers and databases for current intelligence.

Amphibious Task Forces. While afloat, landing forces use the amphibious task force (ATF) imagery architecture to access/transfer GEOINT data. Once ashore, the landing force communications responsibilities transfer to its organic G-6/S-6 for communications.

Intelligence Center. During amphibious operations, the intelligence sections of the ATF and the landing force normally integrate their operations. The principal intelligence C2 node afloat is the intelligence center located aboard the ATF flagship. The intelligence center has installed CIS systems that support the intelligence operations of the ATF and landing force while reducing duplicative functions and producing more comprehensive and timely intelligence for the naval task force. Standard CIS connectivity is available.

Marine Expeditionary Force Command Element

Combat Intelligence Center. The combat intelligence center (CIC) is the principal MAGTF intelligence C2 node providing the facilities and infrastructure for the centralized direction of the MEF's comprehensive intelligence, counterintelligence, and reconnaissance operations. The CIC is the primary IOC established within the MEF main command post. It encompasses the primary functions of the MEF intelligence section and intelligence battalion. The CIC includes the subordinate elements listed in table 4-1 on page 4-4.

Table 4-1. Marine Expeditionary Force Command Element Combat Intelligence Center.

Element	Responsibilities
G-2 Plans	Serves as the G-2 section's main element for coordinating and providing intelligence support to the MEF command element future plans team and leadership of the G-2 sections GEOINT, SIGINT, and METOC sections.
G-2 Operations	Serves as the G-2 section's main element for coordinating and providing intelligence support to the MEF commanding general, battle staff, and current operations center elements; target intelligence support to the force fires and future operations; G-2 section intelligence requirements management activities; red cell support; and MEF intelligence liaison with external commands and organizations.
IOC	Serves as the principal MEF intelligence operations and C2 center established by the intelligence battalion; performs intelligence requirements management, staff cognizance of ongoing organic and supporting collection operations, intelligence production and analysis, and intelligence dissemination.
Support Cell	Serves as the primary element for conducting MEF-wide intelligence requirements management, weather support, collections and dissemination planning and direction, and intelligence staff cognizance of MEF organic and supporting intelligence and reconnaissance operations.
P&A Cell	Serves as the primary production and analysis element of the MEF; processes and produces all-source intelligence products in response to requirements of the MEF; serves as the principal GEOINT production element of the MEF.
SARC	Serves as the primary element for the supervision of MEF collection operations; directs, coordinates, and monitors intelligence collection operations conducted by organic, attached, and direct support collection assets.
Counterintelligence/ HUMINT Company	Serves as the primary element for conducting counterintelligence/HUMINT planning and direction, C2, and coordination of MEF counterintelligence/HUMINT operations with external counterintelligence/HUMINT organizations.
Operations Control and Analysis Center	Serves as the main node for the command and control of radio battalion SIGINT operations and the overall coordination of MEF SIGINT operations; processes, analyzes, produces, and disseminates SIGINT-derived information; and directs the ground based electronic warfare activities of the radio battalion.
Reconnaissance Operations Center	Serves as the main node for the command and control of a force reconnaissance company's operations and the overall coordination of MEF ground reconnaissance operations; processes, analyzes, produces, and disseminates ground reconnaissance-derived information in support of MEF intelligence requirements.

Intelligence Operations Center. The IOC is the other key MEF command element intelligence node. The subordinate elements within the IOC and their typical composition are the support cell, the SARC, and the P&A cell (see fig. 4-1 on page 4-5).

Overall Marine Expeditionary Force Intelligence C2 Relationships. The MEF G-2 section and intelligence battalion's overall C2 relationships, along with the resulting all-source intelligence support flow throughout the MEF are depicted in figure 4-2, on page 4-6.

Combat Intelligence Center/Intelligence Operations Center Operations and Imagery Intelligence. Imagery intelligence is an integral component of many CIC/IOC operations. Key activities include collection, production, and dissemination.

Collection. The CMD section, intelligence battalion, provides the core for MEF CIC collection operations. During operations, the CMD section is located within the IOC support cell.

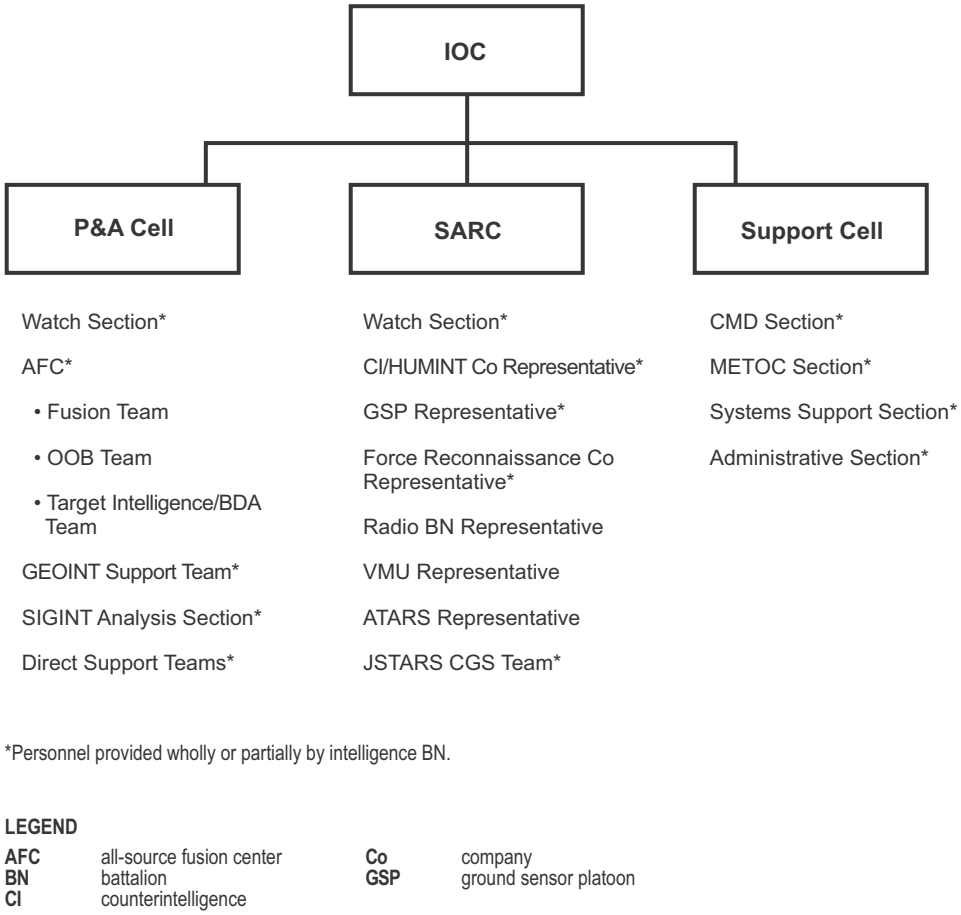

Figure 4-1. Intelligence Operations Center Elements and Composition.

Intelligence specialists from all disciplines are organic to this section. Key CIS resources required include an Intelligence Analysis System (IAS), with community on-line intelligence system for end-users and managers and other specialized applications, and access to the full range of communications (e.g., JWICS, SIPRNET, NIPRNET). The SARC provides the other component of collection operations. The SARC should have representation from most organic and supporting intelligence and reconnaissance units. Imagery intelligence representation should include a VMU element with supporting CIS resources that will monitor ongoing UAS operations and report time-sensitive intelligence.

Production. The P&A cell, intelligence battalion, provides the core for MEF intelligence production operations. Intelligence specialists from all intelligence disciplines are organic to the P&A cell. Key CIS resources required included IAS and the joint deployable intelligence support system, with access to the full range of communications (e.g., JWICS, SIPRNET, NIPRNET). Generally, the IIP and intelligence battalion will be integrated with P&A cell operations to support both IMINT and all-source production operations.

Dissemination. The CMD section, intelligence battalion, provides the core command and control for MEF intelligence dissemination operations. Key CIS resources include IAS and the joint deployable intelligence support system, with access to the full range of communications (e.g., JWICS, SIPRNET, NIPRNET) for external dissemination and IAS via the TDN and other MEF

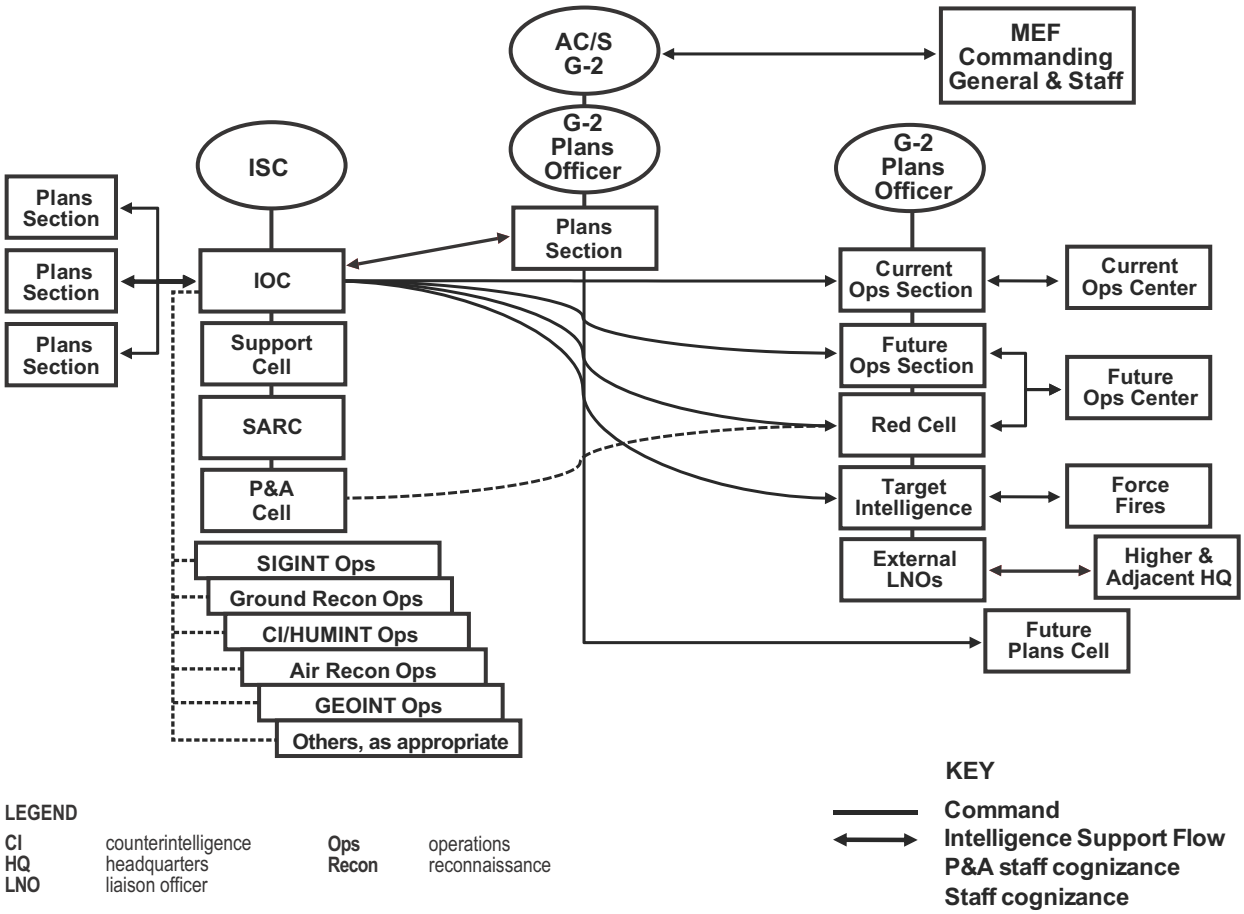

Figure 4-2. Marine Expeditionary Force C2 Relationships and Intelligence Support Flow.

communications resources for internal dissemination. The MEF command element should exploit all of the external capabilities to satisfy its intelligence requirements, with heavy reliance on the MCIA for national imagery support and the JIOC/joint analysis center for theater and national support.

National imagery and related products are received over dedicated terrestrial links that terminate at the MCIA's direct feed imagery product library; standard communications connectivity from the deployed MEF to the MCIA via the Defense Information Systems Network are normally provided by satellite communications. Currently, these links are super-high frequency (X-Band) military SATCOM using ground mobile forces terminals. In the future, more C-Band and Ku-Band commercial SATCOM, using mobile Tri-Band SATCOM terminals, will be employed. The limited capacity of these links to Defense Information Systems Network are a significant chokepoint for deployed MAGTFs. Efficient use of these links is critical to maintaining high traffic throughput.

In addition to the MAGTF TDN and other common-user communications capabilities, several imagery units have specialized capabilities to support IMINT dissemination. The VMU's remote receiving station, attached to MEF MSCs (i.e., the MEF main effort), provides direct, time-sensitive UAS support. Within the MEF, the IAS is the principal information system resource that supports secondary imagery and other IMINT product dissemination. The IAS should be available at all command echelons down to the maneuver battalion/squadron levels. Communications

connectivity between the MEF command element and its MSC headquarters are predominantly provided by SATCOM, supplemented where practical with terrestrial line-of-sight and tropospheric scatter (known as troposcatter) multichannel radio systems. Connectivity to the regiment/group level is principally via the TDN and various multichannel radio resources.

Finally, communications connectivity below the regiment/group command echelon depends on single-channel radio primarily designed for voice traffic, with limited range and limited data capacities. Although these units possess tactical data systems, their ability to exchange data is currently limited due to reduced bandwidth connectivity with the MAGTF TDN.

IMAGERY INTELLIGENCE INFORMATION SYSTEMS AND SUPPORTING COMMUNICATIONS

Imagery Direction and Collection Management

The GEOINT community uses a variety of systems to support and direct MAGTF IMINT operations. The DCGS-MC integrates surveillance and reconnaissance processing and exploitation capabilities into a single, integrated net-centric capability (see fig. 4-3, on page 4-8). Increment 1 of the DCGS-MC will integrate the TEG FoS and the topographic production capability into a common hardware/software baseline for GEOINT support.

The DCGS MC is interoperable with other distributed common ground/surface systems (DCGSs) including DCGS-Army, DCGS-Air Force, DCGS-Navy, DCGS-Special Operations Forces, and DCGS-intelligence community. The use of distributed common ground/surface system integration backbone (DIB) standards allows DCGS-MC interoperability with all other agencies that comply with those standards. These agencies include the NGA, NSA, NRO, DIA, and some allied and coalition forces, as well as the national intelligence architecture. The DCGS MC supports multidiscipline joint, national, multinational (coalition/allied) force commanders, JTF commanders, and below with critical multisource, multi-intelligence data and products to support JTF-level campaign planning and execution.

While embarked aboard amphibious shipping, MAGTF units use the DCGS MC in conjunction with DCGS-Navy assets for all ISR requirements. Once it is transitioned ashore, DCGS MC enterprise provides support to the naval forces through DCGS interoperability. The DCGS MC connects intelligence analysts to multidiscipline national, joint/multinational organic collection assets, data sources, and analytic assessments. It is the backbone of the MAGTF's ability to produce targeting information, correlate surveillance data and other intelligence, and rapidly disseminate information to MAGTF commanders in order to achieve decision superiority.

The DCGS-MC data feeds the COP. The DCGS-MC provides local data discovery and exposes designated MAGTF intelligence data, reports, and products to the DOD DCGS enterprise. The DCGS-MC can integrate sensor data from the broad range of current and planned Marine Corps tactical ISR and nontraditional ISR assets. It accommodates receipt of these data via MAGTF command and control, LANs, the Global Information Grid, and directly from intermediate systems, such as UASs via direct data link, ground control stations, or the removable memory media for ATARS imagery. The DCGS-MC has three nodes: fixed, garrison, and expeditionary.

The MCISR-E fixed site node is hosted at the MCIA and supports information searching, archiving, and collaboration. The MCISR-E fixed site provides data repository services and metadata tagging services that enable a requester to access specific information, data, products, or services. The MCISR-E fixed site is the DCGS-MC exposure site for Marine Corps intelligence data and the Marine Corps metadata registry and catalog. Additionally, when bandwidth restrictions or the characteristics of combat prevent DIB exposure by a deployed MAGTF, the fixed site will serve as an entry point to MAGTF-produced information for national-level intelligence agencies and other external organizations, data, and products.

Garrison nodes, located at each MEF, provide the DCGS-MC with DIB-enabled functional capabilities (i.e., GEOINT, all-source analysis, SIGINT, MTI). They mirror the basic capabilities of expeditionary nodes and, where required, include increased capability (e.g., additional data storage). Garrison nodes can be deployed if necessary. Garrison nodes provide the MEF with the capacity to duplicate capabilities of deployed MAGTFs while serving broader remain behind MEF elements. Garrison nodes are also located at each MEF intelligence center, regional

intelligence training center, and joint reserve intelligence center. These centers provide reachback support to deployed forces, expose data to the larger DCGS enterprise, and provide a baseline intelligence capability for federated production with MCISR-E guidelines.

The expeditionary nodes are linked to the garrison and fixed site nodes. Expeditionary node equipment and capabilities can be scaled to support any size MAGTF. The primary role of the expeditionary nodes is to provide processing, exploitation, analysis, and production capabilities to deployed MAGTFs. When deployed with a MAGTF, expeditionary node capabilities will include the ability to maintain local, tactical intelligence data storage and expose MAGTF intelligence data within the MAGTF, as well as to multidiscipline joint, national, multinational partners. Due to frequent bandwidth restricted operations (i.e., aboard ship or during remote operations), the MAGTF commander retains control of the amount of information exposed directly to the larger DOD DCGS enterprise, MCISR-E garrison nodes, and the fixed site node.

Geospatial Intelligence Information Management Services

Geospatial intelligence information management services provide the MAGTF and other users with a comprehensive national and commercial imagery collection management capability. As the primary tool for imagery collection needs, geospatial intelligence information management services—

- Allow MEF collection managers to generate national and commercial imagery requests, search and order simple to complex GEOINT products, visualize data, and provide mission awareness.
- Enable collection managers to compute, display, and monitor enterprise metrics.
- Task and transmit to collection, exploitation, production, and dissemination organizations the geospatial intelligence needs, formally known as nominations, which, upon validation and prioritization, are automatically transferred to the appropriate review authority.

Imagery Collection

The Marine Corps relies on both organic and external collection assets for its imagery (see fig. 4-4 on page 4-10).

F/A-18D and Advanced Tactical Airborne Reconnaissance System. The ATARS suites are organic to the F/A-18D squadrons (see fig. 3-3 on page 3-12). These ATARS-equipped F/A-18D aircraft provide the MAGTF with an organic manned aerial imagery reconnaissance capability in support of IMINT operations. The ATARS suites are capable of infrared, EO, and radar imagery collection, and provide high-resolution day and night imagery support in all weather conditions through both overflight and long-range standoff.

The F/A-18D's long-range standoff capability is made possible by the upgraded, all-weather SAR system. Imagery is recorded and data-linked via the ATARS sensor suite. The tactical interoperable ground data link II common data link provides a limited NRT capability for disseminating data from selected critical targets—downlinked to the IIP's TEG—with subsequent removable memory media download for the exploitation of the complete track at the squadron. Figure 4-5, on page 4-11, depicts the F/A-18D systems architecture.

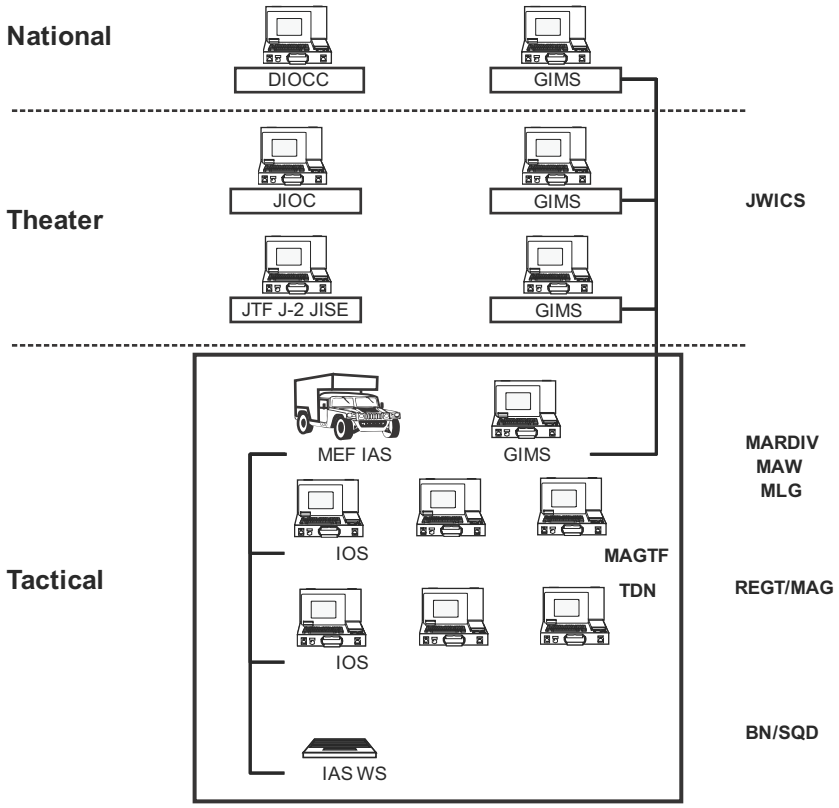

Figure 4-4. MAGTF Imagery Operations.

Unmanned Aircraft Systems. Full motion video feeds have been by far the most effective use of UAS. This live TV coverage of enemy actions or friendly events has contributed more to the commander's situational awareness than any other system in the commander's inventory. See appendix G for additional information regarding UAS equipment and performance characteristics. The following subparagraphs discuss UAS CIS resources.

Remote Video Terminals. Supported units can use/access FMV with a remote video terminal (RVT). The RVT is often the most practical means by which tactical users (e.g., platoon and company commanders, forward air controllers, and air officers) receive video and telemetry information.

The RVT is a ruggedized laptop computer with antenna and software that enable data processing and direct viewing of sensor imagery and telemetry information. Typically, the RVT has limited range (approximately 15 km from the UAS). Some RVTs have much larger directional antennas that can receive video from beyond 45 km. The RQ-7 Shadow is equipped with four one-system remote video transceivers. The one-system remote video transceivers can be used by supported units, such as a regimental COC, to receive video and telemetry from an RQ-7B and certain other types UASs from greater distances.

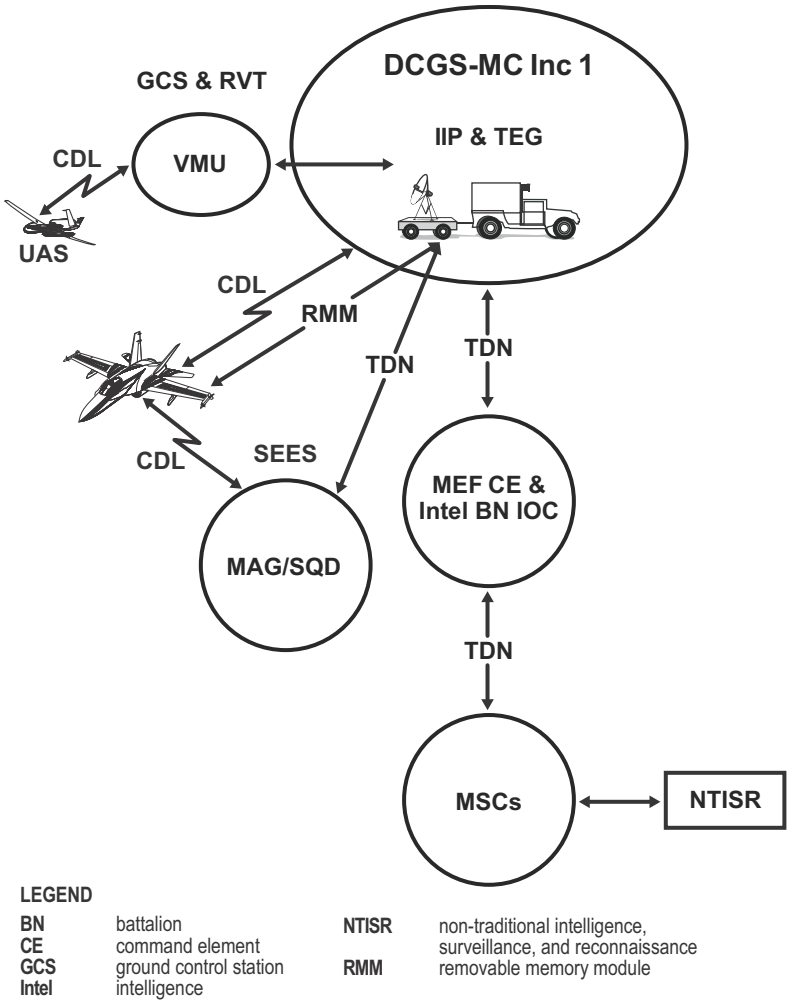

Figure 4-5. The F/A 18D Systems Architecture.

The primary RVT for the Marine Corps is the VideoScout system being fielded to tactical air control parties and battalion air officers. VideoScout can view video on analog or digital L, S, C, and Ku frequency bands.

Video and Data Distribution Networks. Video and data distribution networks provide a multilayer distribution capability that ensures multiple paths for UAS imagery and reduces latency for high priority users.

Supported units in the field can receive video and telemetry directly from the UAS using organic VideoScout or Remote Operations Video Enhanced Receiver III systems. Other units or headquarters equipped with a VideoScout and within range of the UAS can also receive the same video imagery.

For situations where a remote unit or agency desires video and telemetry data, communications architecture that can facilitate the transmission of large volumes of FMV/telemetry data need to be developed by the MAGTF G-6.

Marine UASs provide an interoperable data stream that is compliant with NATO STANAG [standardization agreements]. The data stream interfaces or plugs in to systems devised by the MAGTF G-6. The plug-in would be applied to a system integral to the unit operations center/COC. The unit operations center/COC would then provide the interface for the DCGS-MC. Consequently, all MAGTF units connected to the DCGS-MC should have access to the video/telemetry data provided by the UAS; however, the data should be at an increased level of imagery latency.

Moving Target Indicator Operation Suite. The MTI OS is organic to the MEF intelligence battalion. It provides the MAGTF command element with both communications connectivity with the Air Force's JSTARS E-8C and the capability to display, process, and disseminate acquired information. Figure 4-6 depicts the MAGTF JSTARS systems architecture and CONOPS. The following are capabilities of the MTI OS:

- The MTI OS receives and processes MTI, FTI, and SAR data from the JSTARS E-8C aircraft.
- The MTI OS receives UAS video data via the SIPRNET.
- The MTI OS receives processed SIGINT from the Integrated Broadcast Service.
- The MTI OS receives secondary imagery from theater and national sources.

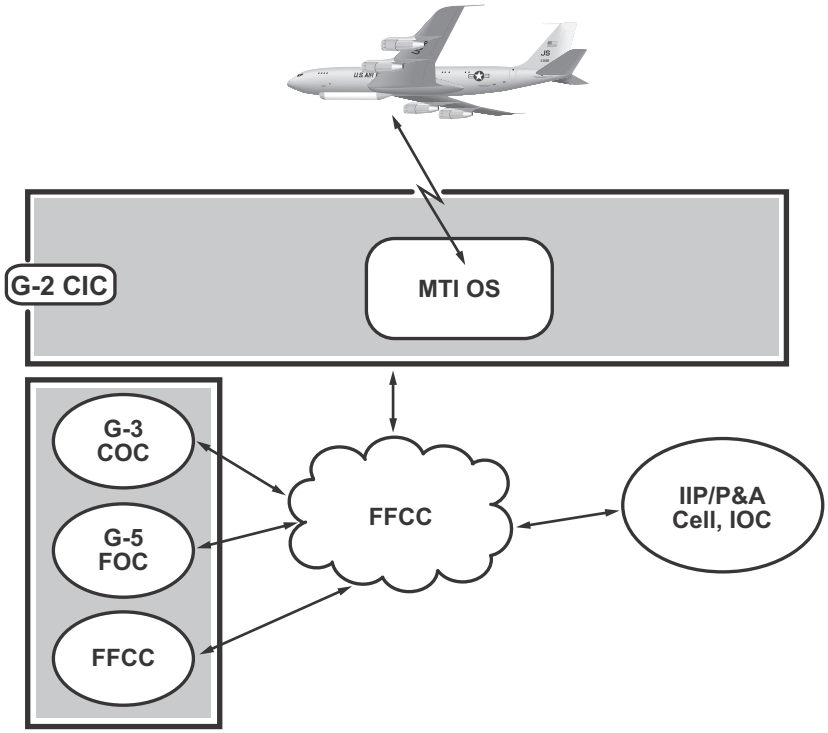

Figure 4-6. Joint Surveillance Target Attack Radar System Common Ground Station Systems Architecture.

- The encrypted, highly jam-resistant SCDL provides the digital communications connectivity between the E-8C JSTARS airborne element and the MAGTF command element G-2 section's MTI OS, enabling the transmission of MTI, SAR, and FTI data acquired by JSTARS to support MAGTF target acquisition, situation development, battlespace management, and targeting functions.
- The MTI OS features an open-system architecture that enables rapid insertion of the latest government and commercial off-the-shelf technology.

Collection Capabilities. The E-8C carries a phased-array radar antenna in a 26-foot canoe-shaped radome under the forward part of the fuselage. With a range in excess of 155 miles, this radar covers an estimated 386,100 square miles in a single 8-hour sortie. It is capable of providing targeting and battle management data to all MTI operators, both in the aircraft and on ground. These operators prepare intelligence reports and/or help coordinate aircraft, missiles, or artillery fire support.

Wide-Area Airborne Surveillance Sensor and Moving Target Indicator. The wide-area airborne surveillance sensor and the MTI are the primary operating modes for the radar. They detect, locate, and identify slow-moving targets. By focusing on smaller terrain areas, the radar image can be enhanced for increased resolution display. High resolution enables analysts to identify moving targets.

Synthetic Aperture Radar/Fixed Target Indicator. The SAR and FTI produce a photo-like image or map of a selected geographic region. A SAR data map contains precise locations of critical nonmoving targets, such as bridges, harbors, airports, buildings, or stopped vehicles. The FTI display is available while operating in the SAR mode to identify and locate fixed targets within the SAR area. The SAR and FTI capability, used in conjunction with MTI and MTI history display, allow for post-attack assessments made by onboard or ground operators following a weapon attack on hostile targets.

Ground Moving Target Indicator Forensics Tool. The MTI OS has a ground MTI forensics tool, which enables it to exploit MTI imagery analysis from points of interest or to compare movement over time. Such comparison enables the development of tracks and the conduct of meaningful historical intelligence analysis. The ground MTI forensics tool gives the MTI OS workstation operators and ground MTI analysis cells the ability to exploit historical MTI imagery from multiple sources.

MAGTF Man-Packed Secondary Imagery Dissemination System. The MAGTF SIDS (see fig. 4-7 on page 4-14) contains multiple configurations consisting of base stations, outstations, and video exploitation workstations depending on each unit's configuration and mission requirements (e.g., MEU structure requires six outstations, three base stations, and one video exploitation workstation). The mission of MAGTF SIDS is to enable the MAGTF to capture, manipulate, annotate, and transmit imagery products in NRT both internally with subordinate commands that are widely separated throughout the AO and externally with higher and adjacent commands (see fig. 4-8 on page 4-15). The MAGTF SIDS is employed according to the doctrine TTP prescribed in doctrinal publications associated with Marine Corps operations. The MAGTF SIDS may be employed in many different scenarios worldwide in which a MAGTF is expected to operate including shipboard, garrison, or tactical environments. The MAGTF SIDS is capable of supporting all phases of operational maneuver from the sea, sustained operations ashore, and other expeditionary operations.

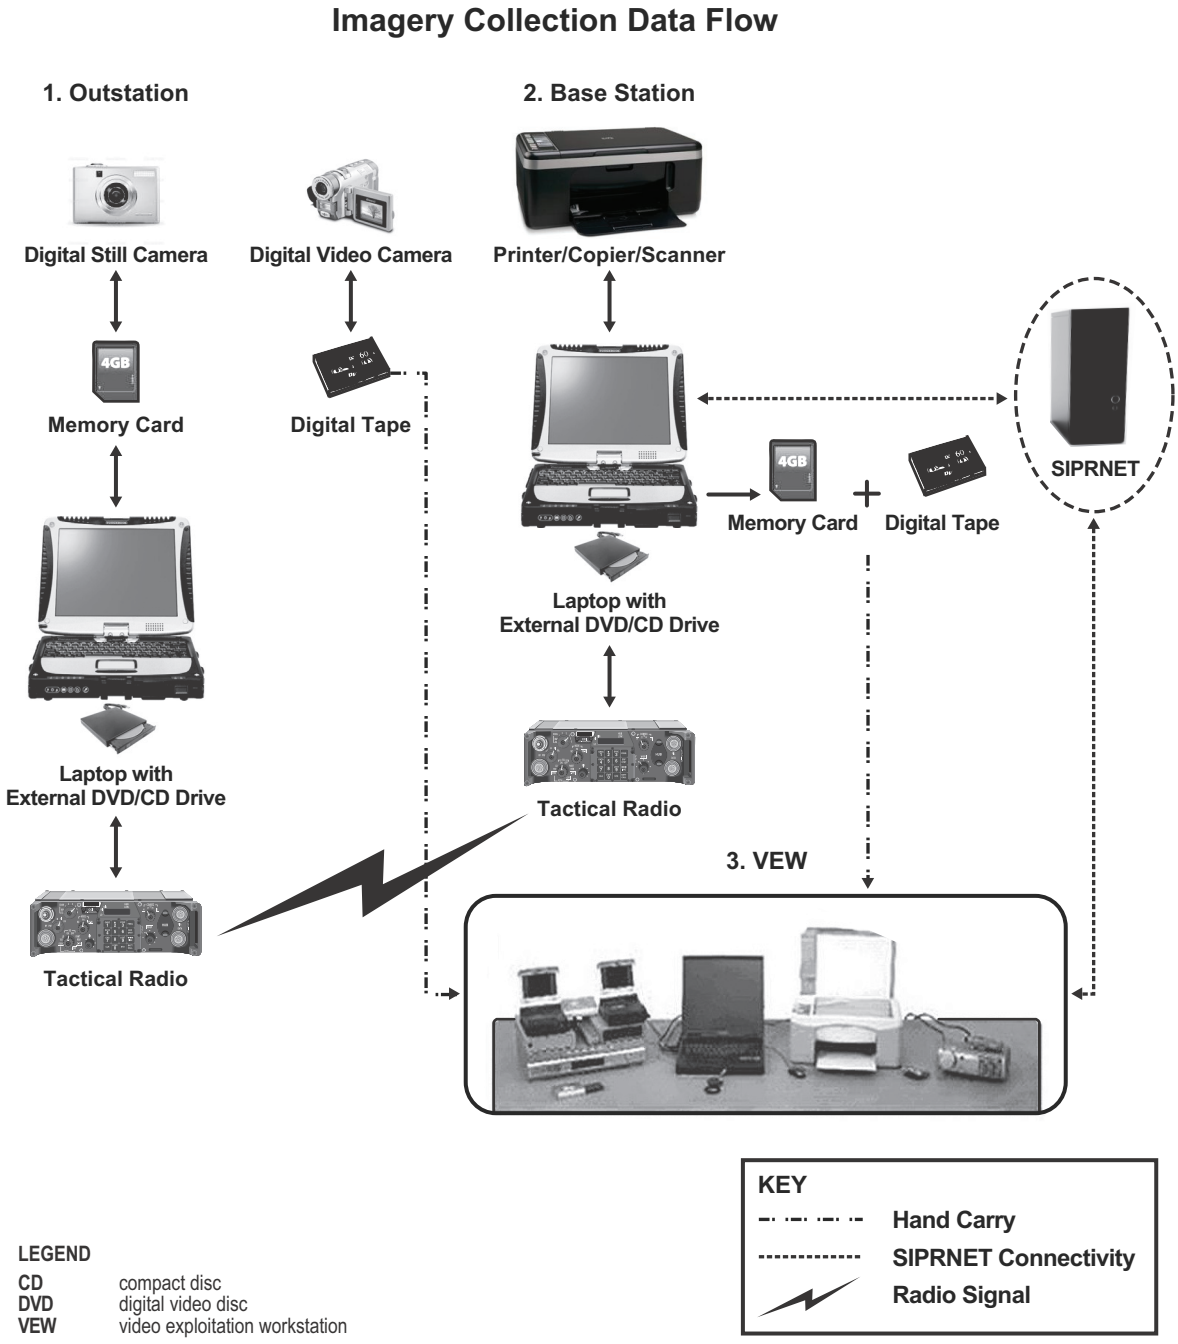

Figure 4-7. MAGTF Secondary Imagery Dissemination System Diagram.

MAGTF Secondary Imagery Dissemination System Base Station. The MAGTF SIDS base station suite is the receiver terminal for the MAGTF SIDS outstation. The MAGTF SIDS base station also provides dissemination and connectivity between the MAGTF and external sources (e.g., theater, national, other Services) via SIPRNET or other organic electronic communications channels that are external to and separate from MAGTF SIDS.

MAGTF Secondary Imagery Dissemination System Outstation. The MAGTF SIDS outstation suite is used to collect and transmit tactical imagery to the MAGTF SIDS base station. The MAGTF SIDS

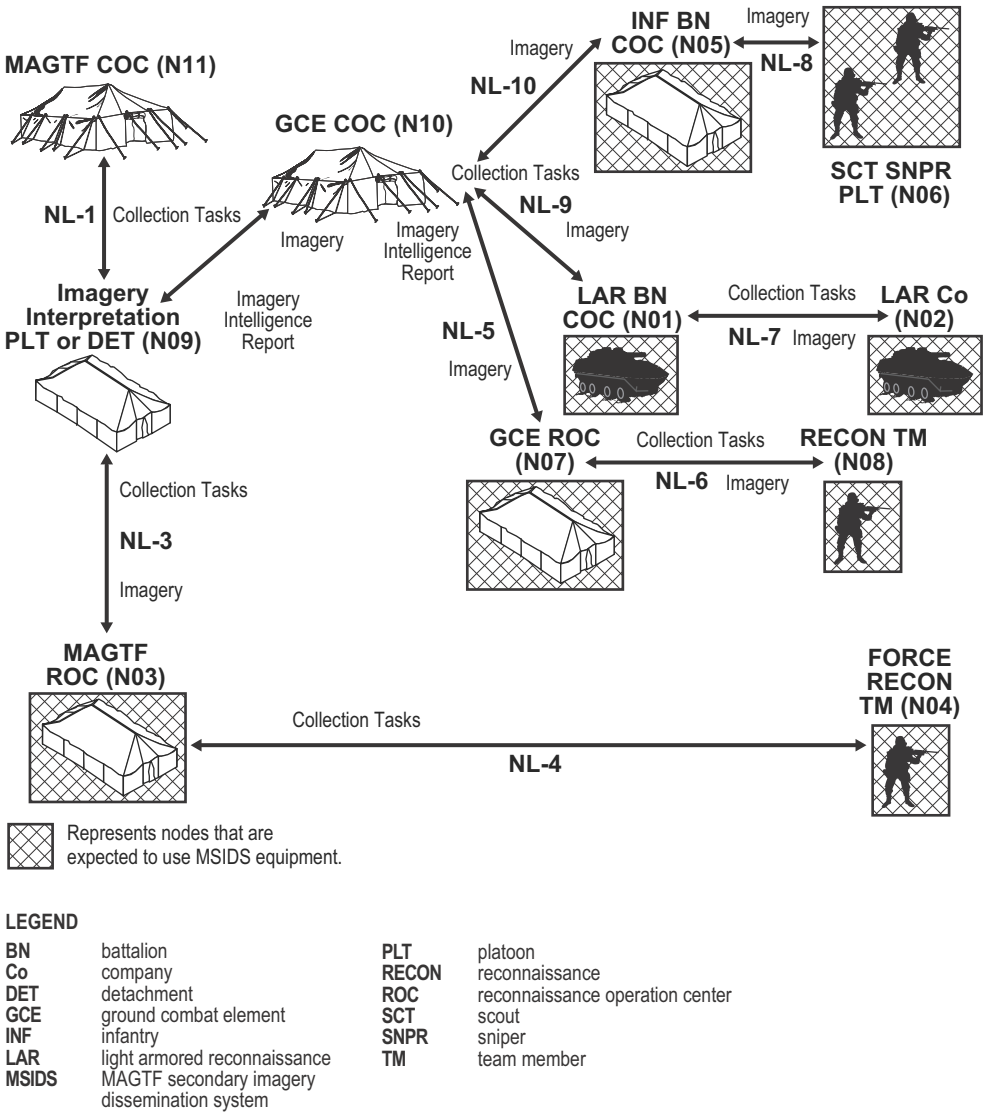

Figure 4-8. MAGTF Secondary Imagery Dissemination System Network Architecture.

outstation also provides dissemination and connectivity between reconnaissance teams and the reconnaissance operation center or command operations center via organic electronic communication channels that are external to and separate from MAGTF SIDS.

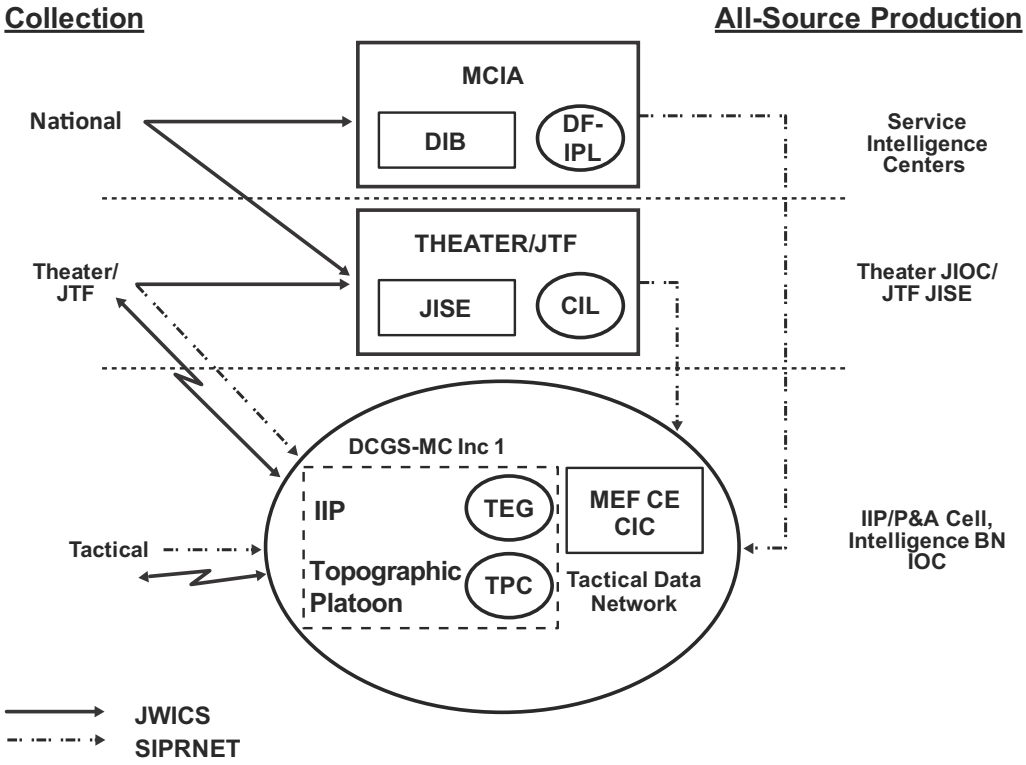
MAGTF Secondary Imagery Dissemination System Video Exploitation Workstations. The MAGTF SIDS video exploitation workstation enables scanning, editing, copying, printing, manipulation, cataloging, and presenting of still and video images from various sources, including captured media. It enables users to select and sort through large amounts of data gathered from either the operating forces or supporting aircraft. Imagery can be imported into the MAGTF SIDS video exploitation workstation in an analog format, such as Hi8, mini-digital video or DV, VHS [video home system] tape. It could also be imported in a digital format through DVD [digital video disc]/CD [compact disc], scanner, directly from a digital camera, with digital camera cards via a multicard reader, or through SIPRNET.

Imagery Tasking, Processing, Exploitation, and Dissemination Capabilities

The Marine Corps possesses organic imagery tasking, processing, exploitation, and dissemination capability. Access to national, joint, theater, and Service processing and production capabilities will therefore be important elements of the Marine Corps imagery architecture (see fig. 4-9). The following subparagraphs provide descriptions of key IMINT processing, exploitation, and production information systems.

Imagery Reachback Site—Marine Corps Intelligence Activity. The MCIA provides 24-hour dissemination of national and commercial imagery to MAGTFs and other Marine Corps units (including the supporting establishment). Dissemination of imagery is accomplished via the Global Broadcast System or SIPRNET. The MCIA's intelligence, imagery, database systems, and requirements include direct feed imagery product library and imagery exploitation support system. The MCIA—

- Receives, stores, and exploits digital NRT imagery from national, commercial, and theater imagery collection platforms.
- Allows general message-level imagery access to Marine Corps elements and a select group of remote clients for imagery analysis.



MCIA and the IIP are the Marine Corps' principal imagery and GEOINT processing and production facilities.
Within the MEF, the principal all-source intelligence processing and production organization is the P&A cell, intelligence BN.

- Provides customers with a search tool for querying its holdings.
- Maintains a current set of national imagery on pre-selected locations relevant to expeditionary operations. These images are updated continually.

Tactical Exploitation Group. The TEG family of systems provides the Marine Corps with a highly mobile tactical imagery ground station capability to analyze aerial imagery from national, theater, and tactical reconnaissance assets and develop imagery products/reports for dissemination in support of both MAGTF and joint operations.

The primary goal of the TEG FoS is to provide responsive imagery exploitation support to the Marine air-ground task force (MAGTF) for tactical operations, strike planning, detection, location of targets of opportunity, and battle damage assessment (BDA) for re-strike planning and intelligence assessment. The Tactical Exploitation Group (TEG) System is the primary tactical imagery exploitation system in the Marine Corps and is one of the capabilities comprising the Distributed Common Ground/Surface System-Marine Corps (DCGS-MC) Geospatial Intelligence (GEOINT). This equipment will be used by the 0241's in garrison, field, shipboard operations, and training exercises. The TEG FoS is comprised of modular and scalable configurations and employs Commercial Off-the-Shelf, Government-Off-the-Shelf, and Non-Developmental Item computer hardware and software to enable rapid upgrade and to maintain commonality with Marine Intelligence and Joint Imagery Systems. The TEG FoS is comprised of the VIP-MC and TEG-RWS (see fig. 3-2 on page 3-4).

Imagery Communications and Information Systems Architecture

Figure 4-10, on page 4-18, and figure 4-11, on page 4-19, depict the internal IMINT CIS architecture for a MEF and the broader IMINT CIS architecture through the theater and national levels.

Geospatial Intelligence Communications and Information Systems Planning Considerations

The MAGTF CIS requirements and planning considerations for GEOINT operations include the following:

- Ensuring the MAGTF command element and subordinate elements are included in the distribution of IMINT-related address indicator groups to receive pertinent tactical, theater, and national intelligence and GEOINT products.
- Determining, establishing, and coordinating communication requirements and operational procedures in support of GEOINT operations.
- Coordinating IMINT CIS activation and restoration priorities and supporting procedures.
- Identifying and procuring community security materiel system requirements for unique IMINT communications.
- Determining and coordinating intelligence network information systems requirements in support of IMINT operations, such as hardware, software, internet protocol addresses, accreditation, or authority to operate/connect.
- Integrating MAGTF IMINT element CIS operations with those of other MAGTF, pertinent JTF, and other components intelligence and reconnaissance units, such as mutual support and cueing.

- Integrating CIS of IMINT elements employed in general support with collocated ground combat element, ACE, LCE, and other MAGTF elements.
- Coordinating MAGTF GEOINT databases administration and operations.
- Coordinating GEOINT CIS and TCPED operations and procedures with other Services, as well as allied and coalition forces.

CHAPTER 5
PLANNING

The following functions are key to planning:

- Developing a plan that directs and coordinates action.
- Fostering shared situational awareness.
- Generating common expectations about how actions will evolve and affect the desired outcome.
- Supporting the exercise of initiative.
- Shaping the thought processes of planners.

SUPPORT TO THE PLANNING PROCESS

When providing support to the planning process the following should be considered: planning for imagery intelligence; types of imagery; aerial imagery collection missions; and processing, exploitation, and dissemination of imagery and imagery intelligence.

Planning for Imagery Intelligence

Planning for IMINT includes implementing the IMINT planning process, integrating imagery intelligence planning with the intelligence cycle, fulfilling imagery intelligence planning considerations, and understanding planning responsibilities.

Imagery Intelligence Planning Process. There are eight steps in the IMINT planning process.

Planning. The first step is to determine the exact needs—including key collection, production, and dissemination requirements—so that priorities are accurately determined, resources are not overwhelmed, and timely support is provided.

Requesting. The most important part of any request is to clearly articulate the IMINT intelligence requirement. Each intelligence request should include the mission and how the intelligence product being sought will fulfill the stated need.

Validating. Intelligence and imagery should be reviewed to determine whether or not the intelligence requirement can be answered immediately. If not, the intelligence requirement should be checked against previously validated intelligence requirements and ongoing/planned intelligence operations to avoid unnecessary duplication. Finally, the intelligence requirement should be checked against the capabilities of the intelligence assets supporting the unit. If the intelligence

requirement is validated using these criteria, then a priority will be assigned to the intelligence requirement and associated intelligence collection, production, and/or dissemination requirements (e.g., ICRs, intelligence production requirements, and intelligence dissemination requirements) will be developed and prioritized.

Planning and Tasking. The collection manager determines the tasking by which the intelligence requirement will be satisfied—either organic or external intelligence operations will be tasked to satisfy the intelligence requirement. If collection is required, the CM/DO determines the best intelligence asset to perform the mission. Concurrently, the CM/DO develops plans and tasks to ensure projected dissemination requirements can be fulfilled, while the geospatial support team develops necessary production plans and tasking. The requirements can be fulfilled using either organic or external assets: when organic intelligence resources are used, appropriate orders shall be issued; when external support is required, the intelligence requirement shall be submitted to either higher headquarters or supporting organizations.

Collecting. The validated ICRs and intelligence production requirements are used to ensure the most effective type of imagery is collected to satisfy the overall intelligence requirements. The capabilities and limitations of each imagery collection element, the time the collection must occur, and the weather influence is the nature of collection operations.

Exploiting. Requirements for IMINT exploitation are defined in terms of three phases. Each phase represents a greater degree of analysis and a longer period of time available to accomplish the exploitation and associated production.

The first phase includes the rapid exploitation of newly acquired imagery, and reporting of imagery-derived intelligence and intelligence information within a specified period of time from the receipt of imagery. Phase one satisfies priority requirements related to immediate needs and/or identifies changes or activity of immediate significance.

Like phase one, the second phase includes the detailed exploitation of newly acquired imagery; however, the reporting of imagery-derived intelligence and intelligence information is weighed by analytic requirements and timeliness of need. Phase two provides for an organized and comprehensive account of the intelligence or intelligence information extracted from newly acquired imagery and is supported by other intelligence source materials, as appropriate.

The third phase includes the in-depth analysis of available imagery pertinent to an intelligence requirement and the reporting of results within a specified time. In response to intelligence requirements, phase three provides the most comprehensive analysis of a target or topic using imagery as the primary data source but, when appropriate, incorporates data and intelligence from other sources. The last steps of this phase are disseminating and utilizing.

Disseminating. Imagery intelligence products are disseminated either as hardcopy or softcopy products. Hardcopy products are disseminated via couriers or the available mail system. Softcopy products may also be distributed as hardcopy products or electronically via the MAGTF communications network. The requestor and the supporting G-2/S-2s, with assistance from units' G-6/S-6, must ensure that the requested product can be transmitted over the available supporting CIS.

Use. As it is with the intelligence process, the last step of the IMINT planning and execution process, effective utilization, is the most important. Commanders and other imagery/IMINT users should notify the G-2/S-2 regularly regarding both the quality of the products and how well particular products answered their CCIRs and intelligence requirements. Additionally, new intelligence requirements that result from new imagery/IMINT should be identified and action should be initiated to plan future operations effectively. Finally, providing the G-2/S-2 and IMINT elements with feedback will help to identify problems and allow improvements to be developed and implemented quickly.

Integrating Imagery Intelligence Planning with the Intelligence Cycle. The intelligence cycle is a procedural framework used for developing mission-focused intelligence support for the range of military operations. The intelligence cycle should be applied in a manner that develops the required intelligence in the most effective way. The application of the intelligence cycle will vary during mission planning and execution. Application of the intelligence cycle is driven by intelligence requirements. In theory, a unique iteration of the intelligence cycle is carried out for each individual intelligence requirement. However, in practice intelligence requirements are grouped together and satisfied through a single, intelligence development process that addresses all intelligence requirements, including IMINT requirements, concurrently.

During planning, the application of the intelligence cycle supports mission analysis, COA development, and COA wargaming by providing basic intelligence, including IMINT, in the form of intelligence estimates, supporting studies, and IPB analyses that describe the battlespace and threat. (See app. C for detailed information regarding imagery and IMINT support to IPB and other all-source intelligence products.)

During COA comparison and analysis, orders development, and transition, the intelligence cycle is applied to satisfy emerging intelligence requirements and update the intelligence estimate and IPB products—all of which may be supported by IMINT.

During execution, the intelligence cycle is applied to implement the intelligence collection, production, and dissemination plan; refine IPB analysis, and generate mission-specific multidiscipline intelligence operations and intelligence products—all of which are integrated with the CONOPS.

During execution, intelligence requirements are satisfied individually. New intelligence requirements are generated in response to specific operational needs. Each intelligence requirement is unique and must be satisfied in a timely manner to facilitate rapid decisionmaking and the generation or maintenance of tempo (see fig. 5-1 on page 5-4).

Imagery Intelligence Planning Considerations. The IMINT plan should reflect proven planning principles. Considerations for IMINT planning are discussed in the following subparagraphs.

Fulfill the Stated Requirements. The IMINT plan should fulfill the stated requirements. It should ensure imagery data is collected, processed, and reported to satisfy the intelligence requirements set forth in the commander's guidance and collection plan. Particular attention must be paid to the timeliness and formats of the data provided.

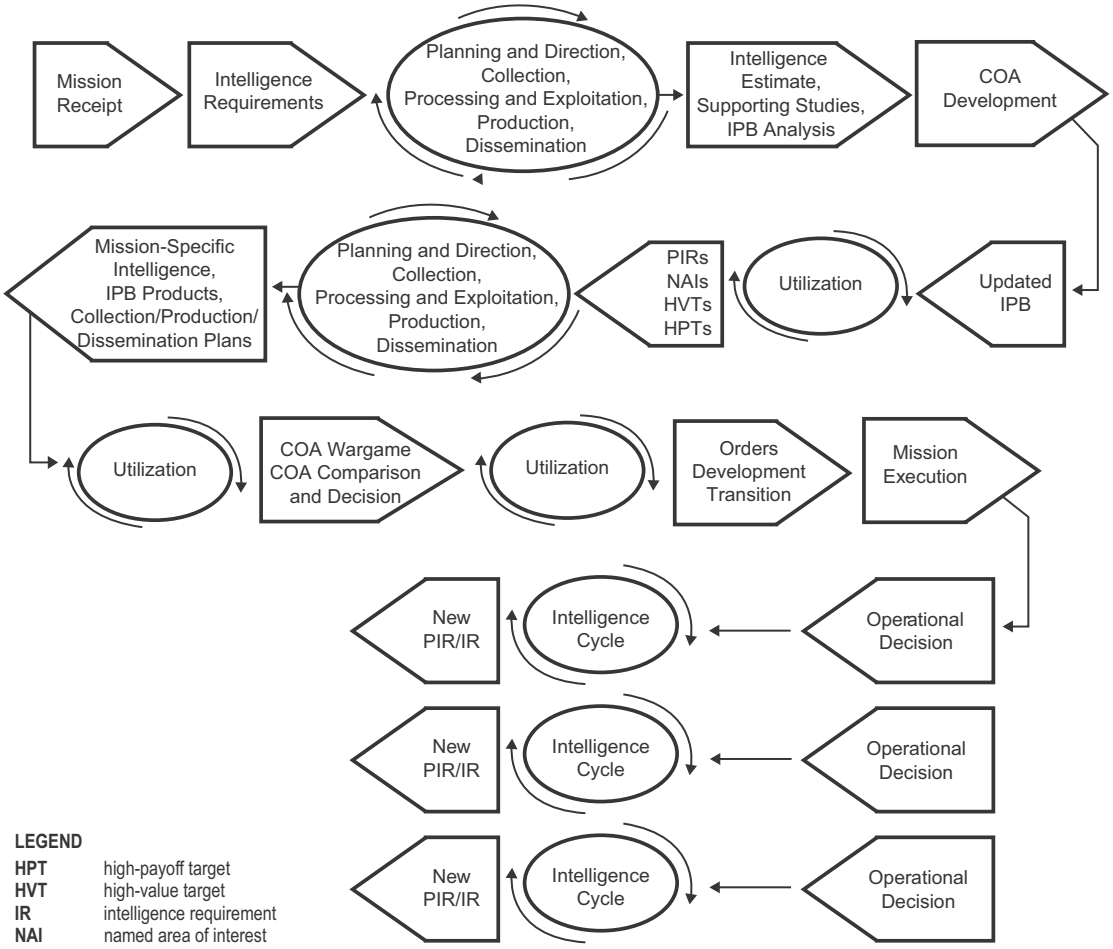

Figure 5-1. Application of the Intelligence Cycle.

Integrate with Other Intelligence Plans. The IMINT plan should be integrated with other intelligence plans. Effective IMINT planning and execution require close coordination, liaison, and integration with all-source intelligence elements. Frequently, IMINT collection management is driven by cross-cueing from SIGINT, HUMINT, and other sources of intelligence. Also, fusion of IMINT with other intelligence ultimately drives the conduct of future IMINT operations and the development of IMINT products.

Integrate with Other Operations. The IMINT plan must take into account the location and activities of the supported units. Planned missions must be scheduled where and when they can best collect sensor data. Additionally, C2 and CIS arrangements must be coordinated in order to ensure imagery data and IMINT are reported to the supported units. Because enemy activity may be anticipated at certain phases of military operations, IMINT operations and analytical personnel must have a situational awareness of both intelligence estimates and ongoing operations to focus their efforts at a particular time and area. Finally, the requirement for timeliness in processing and reporting may vary depending upon the stage of the operation; personnel must be aware of current timeliness requirements as well as the availability of CIS resources with all supported commands.

Integrate into the Overall Collection Plan. The IMINT plan should be integrated with other intelligence and reconnaissance operations to ensure the required data can still be acquired even when a planned

imagery mission is canceled or critical equipment malfunctions. The ability to provide this redundancy depends upon the number of imagery missions available, capability of other intelligence resources to acquire the information needed, and the availability of production resources.

Make Use of All Imagery Intelligence Resources. The IMINT plan should make use of all IMINT resources. While some imagery collection resources may be held in reserve, most units and systems can fulfill multiple missions and should be employed. Close coordination and integration of operations and intelligence activities will aid with identifying and prioritizing these multipurpose missions. Imagery intelligence production resources should not be held in reserve.

Support the Concept of Operations. The IMINT plan should support the CONOPS. Imagery intelligence efforts must support and adapt to the MAGTF commander's intent, concepts of intelligence and operations, and the supporting scheme of maneuver. Key questions to be answered regarding supporting the CONOPS include—

- What are the MAGTF AO and the AOI?
- What are the MAGTF CONOPS, task organization, and main and supporting efforts?
- What are the standing PIRs and intelligence requirements? Which have been tasked to supporting IMINT units? What specific information most interests the commander (e.g., enemy ground operations, enemy air operations, target BDA, friendly force protection, or enemy future intentions)?
- What is the concept of MAGTF fires support? How will MAGTF target development and target intelligence be conducted? What are the specific imagery needs in support of these tasks?
- What are the IMINT and intelligence CONOPS of other JTF, component, and/or theater resources? What are the task-organization and command/support relationships for all MAGTF intelligence and reconnaissance units?
- How can external assets be incorporated to support MAGTF operations?

Take Into Account the Physical Environment. The IMINT plan should take into account the physical environment, including terrain and weather. Terrain factors have a significant impact on IMINT operations, such as the ability of IMINT sensors to see through vegetation and IMINT's requirements for line of sight (LOS) communications. To be effective, all IMINT collection systems require LOS to the target area. Accordingly, IMINT planners must assess the effects of mountains, defilade, vegetation, and other potential terrain obstacles on all planned IMINT operation.

Consider Weather as a Key Limiting Factor. Bad weather degrades the identification and location of targets and can limit the type of imagery collection capabilities that may be employed. In addition, low ceilings and poor visibility decrease both visual reconnaissance effectiveness and the resolution of photographic systems. Weather factors to consider include the following:

- *Precipitation*. Visible moisture degrades optical and visual reconnaissance systems. Most UASs are not all-weather aircraft. Consequently, rain, ice, and snow can severely damage or even destroy a UAS.
- *Wind*. UASs are significantly more affected by wind than manned aircraft.

- *Clouds, Haze, and Smoke*. In addition to affecting the aircrew's ability to conduct visual reconnaissance, cloudy, hazy, and smoky conditions also affect EO and infrared systems on both manned aircraft and UASs.
- *Daylight, Sun Angles, and Shadows*. The angle of the sun affects visual, EO, and forward-looking infrared (FLIR) observations differently. The quality of FLIR imaging decreases as the sun rises and reaches a point where a target can be seen visually. At this point the target cannot be detected by a FLIR. Prior to sunset and just after sunrise, long shadows are cast by large terrain features and can obscure objects in their path. The ideal time to take photographs or observe a target is mid-morning or mid-afternoon. During these periods, shadows are cast long enough to add definition and dimension to a target.

Consider the Threat. Threats can be general or aviation related. For a general threat, a detailed threat analysis must be conducted to determine which imagery sensors and platforms can be employed effectively against a given enemy target, and then how to employ the limited resources available to the MAGTF to obtain the required IMINT. The enemy can, in turn, impede imagery operations by employing CCD activities as well as focusing their air defense capabilities.

Enemy air defenses have a direct effect on aerial imagery collection missions. Since aircraft must stay beyond threat air defense ranges, significant antiaircraft artillery (AAA) and surface-to-air missile (SAM) threats may degrade visual reconnaissance. Imagery intelligence planners must assess threat air defense and air-to-air threats when evaluating risk and determining routes. Finally, threat EW capabilities must be identified and assessed in order to determine their effects on UAS and manned imagery platforms radio uplinks and imagery downlinks.

Consider the Type of Collection. The IMINT plan shall consider the various types of imagery collection capabilities. A variety of organic imagery collection capabilities are available to a MAGTF (see fig. 5-2 on page 5-7). The following planning considerations are critical to effective direction and employment of these resources. Imagery collection resources readily locate and identify large threat forces, moving vehicles, weapon systems, structures and other topographic features that contrast with their surroundings. Conversely, small, stationary/well-camouflaged enemy forces blending into their surroundings can be difficult to locate and identify. Generally, it is better to employ imagery collection resources against point targets rather than in a wide area search mode. Effective integration with other intelligence operations can cue imagery collectors to key targets, reducing the search area, thereby reducing the time required to produce actionable intelligence.

Area Reconnaissance. Area reconnaissance is the systematic and complete coverage of an area using visual/imaging means. Area reconnaissance is normally used to locate/identify specific targets for further collection and analysis. It is also used to support terrain analysis. Area reconnaissance imagery can be collected two different ways: first, by imaging back and forth across a predetermined area so that flight lines and individual images overlap—this process provides complete coverage of all objects within the area at the expense of increased sensor utilization time; second, by adjusting focal lengths/altitudes to allow a lesser number of images to cover the target area. This process reduces time on target (TOT) as well as the processing, exploitation, and dissemination time at the expense of reduced resolution. Types of area reconnaissance imagery missions include broad area coverage/surveillance and directed search area missions.

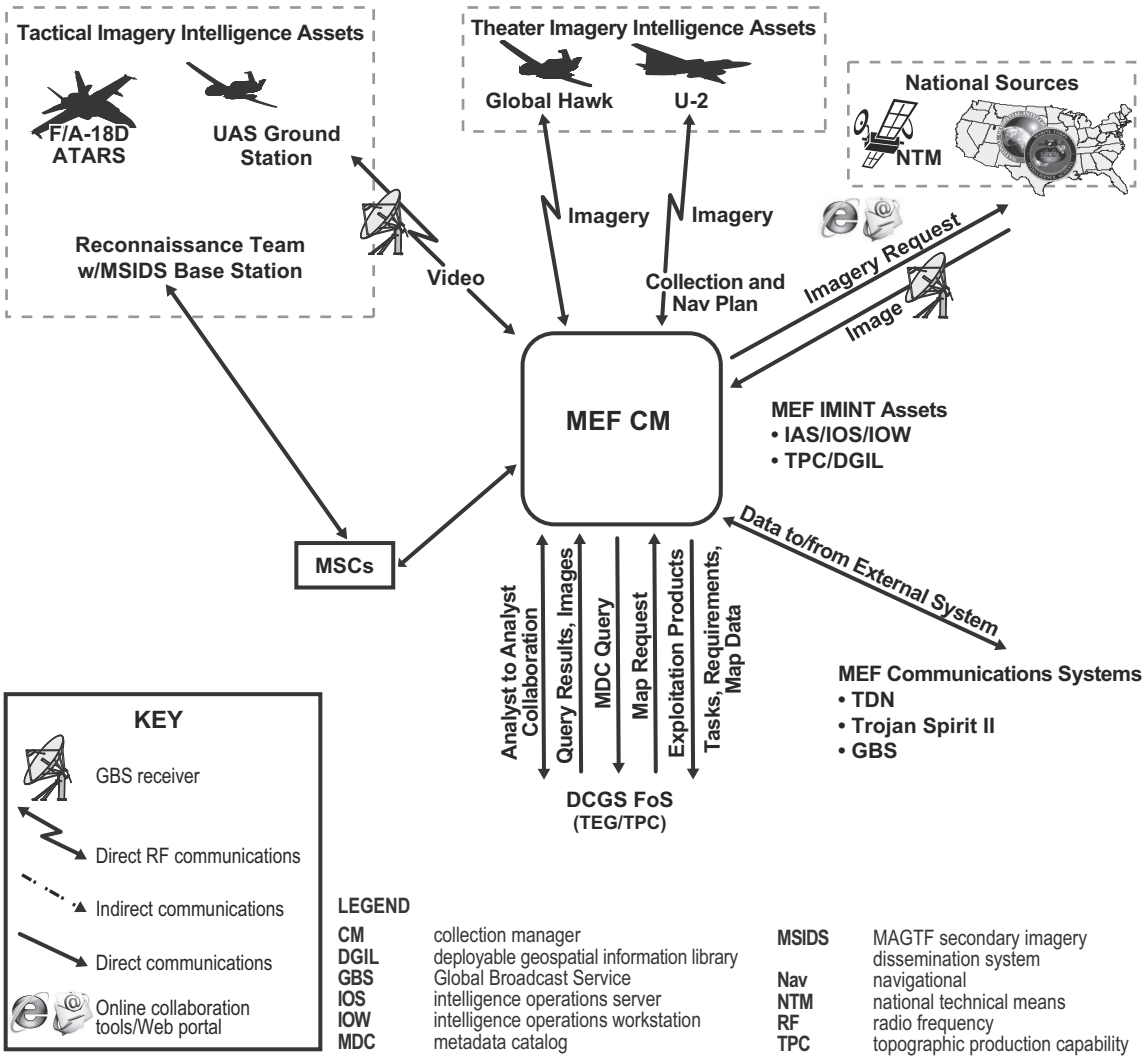

Figure 5-2. Marine Expeditionary Force Imagery Collection Capabilities.

Broad area coverage/broad area surveillance are area reconnaissance imagery collection tactics that provide an overview of an entire area. They should not be the primary collection tactics utilized to collect against known point targets. (During area collection operations, the flight tracks/ routes are planned and the image exposures adjusted so that each successive image will overlap the previous one.) During the early phases of an operation broad area coverage and broad area surveillance may be conducted for two intelligence purposes: first, providing a basis for the procurement of larger scale imagery of selected areas for subsequent detailed analysis; second, serving as a comparative baseline for determining the nature and extent of changes identified on subsequent missions.

Directed search area missions provide focus and detail, and are useful for OOB confirmation counts.

Point Targets. Point targets are normally tasked to provide the highest possible resolution of a specific target that allows for detailed analysis. Point targets can vary in size and include command posts, bridges, airfields, and SAM sites.

Line of Communications. Line of communications collections involve imaging along specific transportation routes, such as roads, railroads, or waterways. This type of reconnaissance is normally conducted to determine enemy movement or potential usability of a route; it can also support mapping or terrain analysis requirements. This methodology is good for maneuverability studies, but generally requires significant time for effective exploitation. Line of communications missions should be conducted ahead of time as a contingency baseline.

Planning Responsibilities. Imagery intelligence planning is a continuous function that requires close interaction between the G-2/S-2 and IMINT unit planners. Key objectives include the following:

- Identifying IMINT requirements.
- Preparing IMINT operations plans.
- Planning and establishing the IMINT support system.
- Issuing orders/tasking to IMINT units.
- Supervising and coordinating IMINT operations.

Assistant Chief of Staff G-2/S-2. Primary staff responsibility for the planning of IMINT operations lies with the AC/S G-2/S-2. Specific responsibilities of the AC/S G-2/S-2 include the following:

- Preparation of integrated, multidiscipline intelligence and reconnaissance operations and supporting IMINT plans, orders, annexes, and appendices.
- Coordination with the G-3/S-3 to ensure the planned IMINT plan supports both the CONOPS and scheme of maneuver.
- Coordination with the G-6/S-6 officer for CIS support to the IMINT elements, including circuits, network access, frequency assignment, equipment, and call signs.
- Liaison with IMINT agencies and units external to the MAGTF. Identifying, preparing (including all required equipment), and locating IMINT or all-source intelligence liaison elements to support MAGTF IMINT operations is a critical early planning action. The IMINT liaison teams will be small in number due to the limited availability of imagery personnel.
- Coordination with the G-4/S-4 to ensure adequate logistic support of IMINT elements.

Intelligence Battalion Commander/Detachment Officer in Charge. The intelligence battalion commander/detachment OIC is responsible to the AC/S G-2/S-2 (or in some cases the MAGTF intelligence operations officer) for the planning, direction, and execution of MAGTF IMINT operations. Specific duties of the battalion commander/detachment OIC include the following:

- Advising the G-2/S-2 on IMINT employment and its integration with other Services, JTF, theater, and national IMINT operations.
- Preparing MAGTF IMINT plans and orders in conjunction with other intelligence section staff officers and key intelligence battalion subordinates.
- Planning, supervising, and assisting IMINT collection requirements and tasking for MAGTF operations, in conjunction with the CM/DO.

- Coordinating the movement, operation, and reporting of IMINT units in coordination with the SARC OIC and the G-3/S-3.
- Coordinating MAGTF IOC analyst exchanges with IMINT analysts and the integration of GEOINT products with all-source intelligence production in conjunction with the MAGTF IOC OIC. The battalion commander/detachment OIC must take into account the strenuous mental and physical demands on imagery analysts during sustained operations, particularly when planning watch schedules for imagery analysts performing detailed imagery exploitation tasks.
- Planning for the timely reporting of IMINT to both MAGTF and external elements and the rapid handling of time sensitive information in coordination with the CM/DO.
- Planning and coordinating IMINT communications paths and information systems management and operations in conjunction with the G-6/S-6.

Types of Imagery

The types of imagery are electro-optical, infrared, radar, multispectral, hyperspectral, and commercial. Certain policies apply to imagery of the United States.

Electro-Optical Imagery. Electro-optical imagery employs digital imaging techniques to extend and complement other imagery. Electro-optical imagery is readily exploitable by automated processors and analytical aids. It uses the visual spectrum, so anything that impacts this spectrum, such as dust, smoke, haze, clouds, rain, fog, light level, or angle of illumination, will affect the quality of the imagery.

Infrared Imagery. Infrared imagery systems can operate day or night under favorable weather conditions. They are less effective during day/night transition periods or when backgrounds and targets have negligible differences in temperature.

Infrared imagery is the remote sensing of the radiant temperature associated with a target. The system is used to measure the temperature differences between terrain features and surrounding objects on the ground, producing a near-optical-quality infrared image (see fig. 5-3 on page 5-11).

Unique infrared imagery capabilities include imaging the shadow on a heat-absorbing surface or the thermal scar of a heat-generating object.

Radar Imagery. Radar imagery can be collected day or night and under all weather conditions. Generally, it is limited only by the capability of the platforms conducting the collection mission. Radar imagery is best utilized in conjunction with other imagery sensors. Unlike EO imagery, it presents a nonliteral image of the battlespace, requiring special skills and time to analyze properly. See figure 5-4, on page 5-10, for an example of SAR imagery.

Radar Reflection. Radio-frequency energy is transmitted to and reflects from the reflecting object. A small portion of the energy is reflected and returns to the radar set. This returned energy is called an echo, just as it is in sound terminology. Variations in the pattern and tone of the echo are recorded and displayed as radar images.

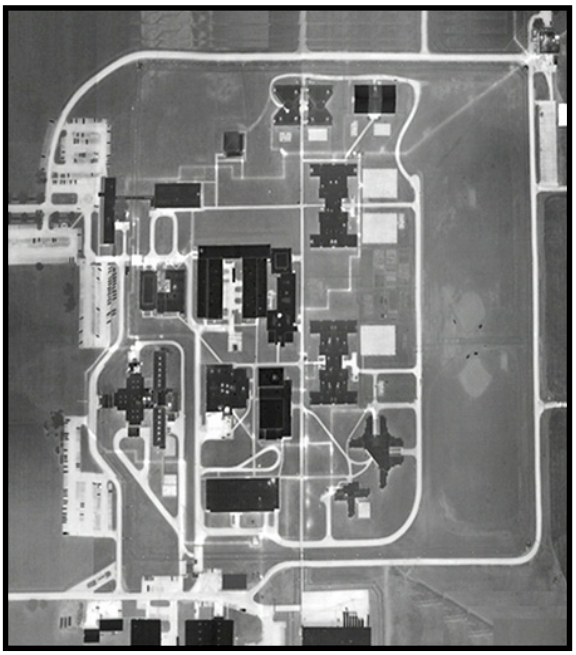

Figure 5-3. Infrared Imagery.

Figure 5-4. Synthetic Aperture Radar Imagery Example.

Doppler Shift. The geometry and surface composition of targets and their surroundings can greatly affect the intensity of the radar pulse return. To detect moving targets, radars employ the principle of Doppler shift. Doppler shift is the result of a moving object causing a subtle change in the frequency of the reflected pulse energy. This change is detected by comparing the original pulse energy frequency to the frequency of the reflected energy. See figure 5-5, on page 5-11, for an example of an MTI image.

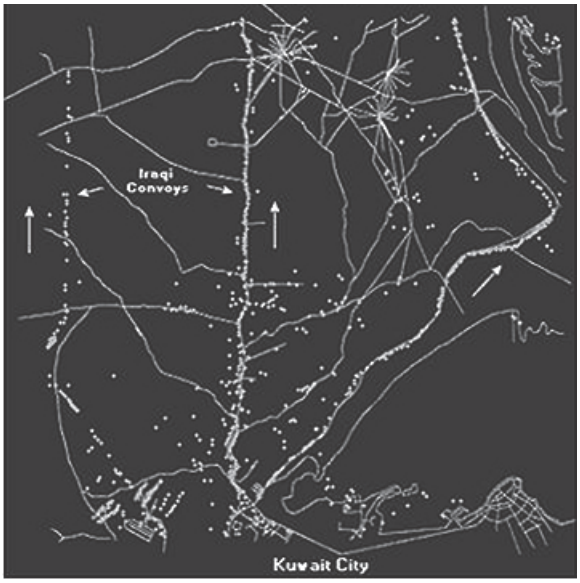

Figure 5-5. Joint Surveillance Target Attack Radar System Moving Target Indicator Imagery.

Multispectral Imagery. Multispectral imagery records multiple views in several spectral bands or frequencies simultaneously. The key to interpreting these images lies in the identification of the spectral signatures of the various surfaces and targets. Whether it is generated by itself or reflected, every surface or target gives off a unique pattern of radiation. The shape of the pattern depends on the reflective qualities of the material, its heat, whether it is a solid or liquid, the smoothness of the surface, and several other factors.

Hyperspectral Imagery. Hyperspectral imagery sensors use hundreds of very narrow wavelength bands to *see* reflected energy from objects on the ground. This energy appears in the form of "spectral fingerprints" across the light spectrum. Once these fingerprints are detected, special algorithms—repetitive, problem-solving mathematical calculations—are used to assess them so that various natural and manmade substances can be differentiated from one another. Signature libraries may also be used to identify specific materials, such as rooftops, parking lots, grass, or mud, by comparing a library's pre-existing reference catalogs with freshly taken hyperspectral images of the battlefield from space. Image processing equipment then portrays the various types of terrain and objects upon it in different colors forming a "color cube," each based on the wavelength of the reflected energy captured by the image. These colors are subsequently "translated" into maps that correspond to certain types of material or objects to detect or identify military targets, such as a tank or a mobile missile launcher.

Commercial Imagery. The commercial imagery industry has launched and will continue to launch new high-resolution panchromatic, multispectral imagery, and other imagery systems. These systems will provide an increased capability to supplement and complement our national imagery technical collection. The HQMC Imagery and Geospatial Intelligence Branch works closely with NGA on commercial imagery issues. Marine Corps policies and procedures for requesting, tracking, obtaining, and purchasing commercial imagery are under development. These policies and procedures are promulgated from NGA's Commercial Imagery Management Office, which publishes commercial imagery plans that improve DOD and intelligence community access to commercial imagery.

Domestic Imagery Collection. Domestic imagery collection includes satellite and aerial imagery of any part of the United States and its territories or possessions, including the 12 nautical miles seaward of these land areas. Before domestic imagery collection in the aforementioned geographic areas may be conducted, an approved proper use statement is required. Central to this process is a thorough review of planned missions to ensure that the constitutional rights of US citizens are protected according to current laws and executive orders restricting intelligence activities directed against US citizens within the United States. Approved proper use statements must be retained in the permanent files of the requesting unit and higher headquarters up through the combatant command headquarters. For additional information on domestic imagery collection, see NGA Imagery Policy Series [IPS] [section 9, part B], Domestic Imagery [IPS-001/98-S9A]. Request channels for domestic imagery collection are Marine Corps-specific requirements (proper use statements are submitted via the service chain of command to the MCIA/DRO) and joint operations requirements (proper use statements are submitted via the operational chain of command to the combatant commander for adjudication or follow-on action, as appropriate).

Aerial Imagery Collection Missions

Aerial imagery collectors provide the flexibility to respond rapidly to changing battlespace conditions. Unmanned aircraft systems provide both the added advantage of operating in areas of heavy enemy air defenses and the needed intelligence without the risk of exposure of manned aircraft. Intelligence imagery collection planners establish detailed preplanned imagery collection routes, areas, and point targets encompassing the AOI using the results of IPB, the MAGTF's CONOPS, and scheme of maneuver.

Aerial imagery collection missions require detailed operational planning, particularly with respect to their integration with other ACE operations. Since all aerial imagery collection platforms are multipurpose, close coordination between MAGTF command element imagery planners and ACE operational planners is necessary to identify, reconcile, prioritize, and integrate competing requirements for resources. Additionally, all aerial imagery missions must be included on the ATO and coordinated with other air operations and, where pertinent, supporting arms. This coordination is particularly critical with regard to UAS operations. Unmanned aircraft systems enter the airspace control system via the appropriate airspace control agency, normally the DASC. Unmanned aircraft system controllers maintain communications with the appropriate ACE C2 agency, such as the DASC, during missions in order to receive routing, altitude, and other pertinent airspace control information.

The commander who directly tasks or controls an imagery collection mission will receive the most responsive support. The responsiveness of the mission to other commanders depends on the number of echelons through which the mission request and resulting intelligence must flow. Accordingly, when planning imagery collection operations, the advantages and disadvantages of dedicating missions to a single command (i.e., direct support) must be assessed against the MAGTF's total intelligence requirements and the current situation. Previously acquired imagery and IMINT products should always be reviewed to see if they can satisfy intelligence requirements without need of additional imagery collection missions.

Often, the intelligence acquired from an imagery collection mission (vice the actual image) will be all that is required to satisfy many intelligence requirements. Likewise, dissemination challenges

are generally simpler and faster when users' intelligence requirements can be satisfied without the images. Accordingly, to ensure optimum support, commanders must understand the pros and cons of various imagery-related intelligence requirements.

Usually, collected imagery will require additional processing and fusing with other intelligence to provide the necessary support. Depending on the situation, this may be a time-intensive task. Commanders should assess likely processing and production timelines and other requirements when developing IMINT plans.

Intelligence acquired from a number of imagery collectors may be disseminated directly to users with minimal additional intelligence processing and all-source intelligence analysis. Supporting dissemination plans must ensure identification of the type products likely disseminated as well as the technical requirements associated with these products. In the case of resources, such as the UAS or JSTARS, dissemination planning includes the establishment of dedicated communications links directly between the collector and the supported unit.

Preplanned Missions. Preplanned aerial imagery missions (e.g., UAS, ATARS) are requested using the joint tactical air reconnaissance/surveillance (JTAR/S) request format (see app. H, section I). Within the MAGTF, preplanned aerial imagery requests are routed through the intelligence chain and consolidated by the MAGTF command element's intelligence section for validation, prioritization, and follow-on planning and coordination.

Immediate Missions. Immediate requests for aerial imagery collection will be submitted via the operational chain of command to the DASC. However, this is rarely done because available resources are generally limited and operate in general support of MAGTF requirements. The joint tactical air strike request format (see app. H, section II) may be used to request immediate aerial imagery collection support. When approved, the mission may be executed in one of the following ways:

- An ongoing mission can be diverted by its controlling authority to conduct the immediate mission.
- An on-call/standby mission may be allocated.

Air Planning and the Air Tasking Cycle. The air tasking cycle is the key tool used by MAGTF planners to plot most air operations (i.e., pre-planned and immediate) to support mission accomplishment. By using and completing the air tasking cycle, planners can ensure that, with correct prioritization, aviation assets can be used most effectively, while maintaining command and control and CIS in support of the MAGTF.

The Air Tasking Order. The principal planning product of the air tasking cycle is the MAGTF ATO or air plan. The ATO is a document generated by the joint force air component commander or the ACE commander. It tasks and disseminates the specific missions and targets of projected air sorties, capabilities, and forces to JTF components, subordinate units, and C2 agencies. It normally provides both general and specific instructions, including call signs, targets, and controlling agencies. The airspace control order is included in the ATO. Special instructions that provide amplifying notes, important details, and changes are included in the ATO or issued

separately. The ATO, airspace control order, and special instructions provide operational and tactical direction at appropriate levels of detail. For further information on the air tasking order, see MCWP 3-25.

Phases of the Air Tasking Order. The six phases of the ATO cycle are command aviation guidance, target/air support mission development, allocation and allotment, tasking, force execution, and combat assessment (see fig. 5-6).

Requesting Joint Task Force, Theater, and National Imagery Support. Significant imagery and IMINT support is available to the MAGTF from external sources, ranging from dissemination of existing imagery and products through the integration of existing information into new products and execution of new imagery collection and IMINT production. Those MAGTF intelligence requirements that cannot be satisfied by organic resources will be submitted to the next higher command echelon for validation, prioritization and, if possible, satisfying the RFI or collection requirements through its organic resources, before forwarding it to the next higher command echelon. The specific intelligence requirement will determine how the requirement is identified and submitted. Techniques include the use of the standard RFI and the use of collection/ production management systems and procedures. Figure 5-7, on page 5-15, identifies the two different tracks external imagery and IMINT requirements may take.

Processing, Exploitation, and Dissemination of Imagery and Imagery Intelligence

Processing. The processing of imagery and IMINT involves the conversion of collected data into information that is suitable for the production of intelligence.

Exploitation. The exploitation of imagery and IMINT is the activity that converts information into intelligence. It fuses new information and existing intelligence from all sources to provide

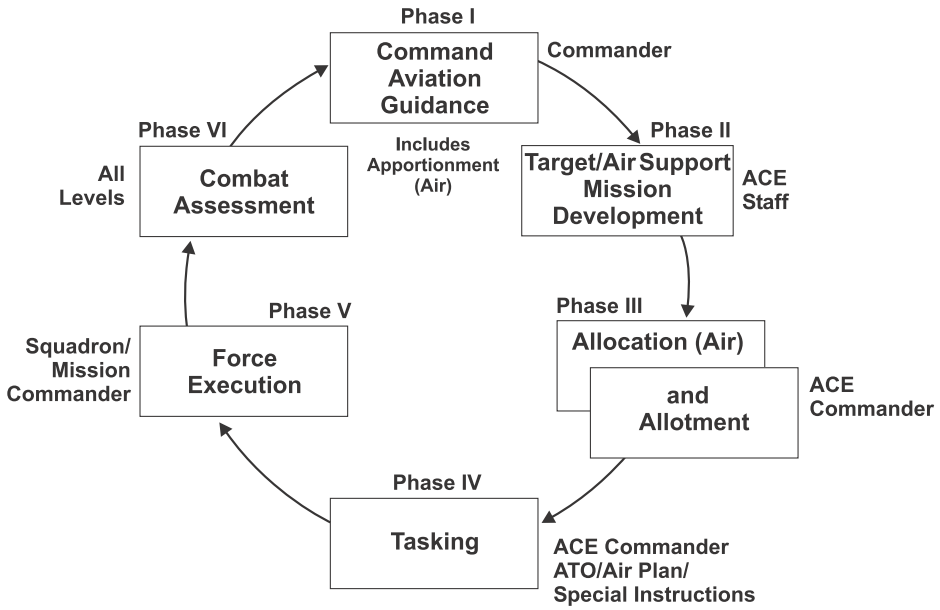

Figure 5-6. The Six-Phase Aviation Tasking Cycle.

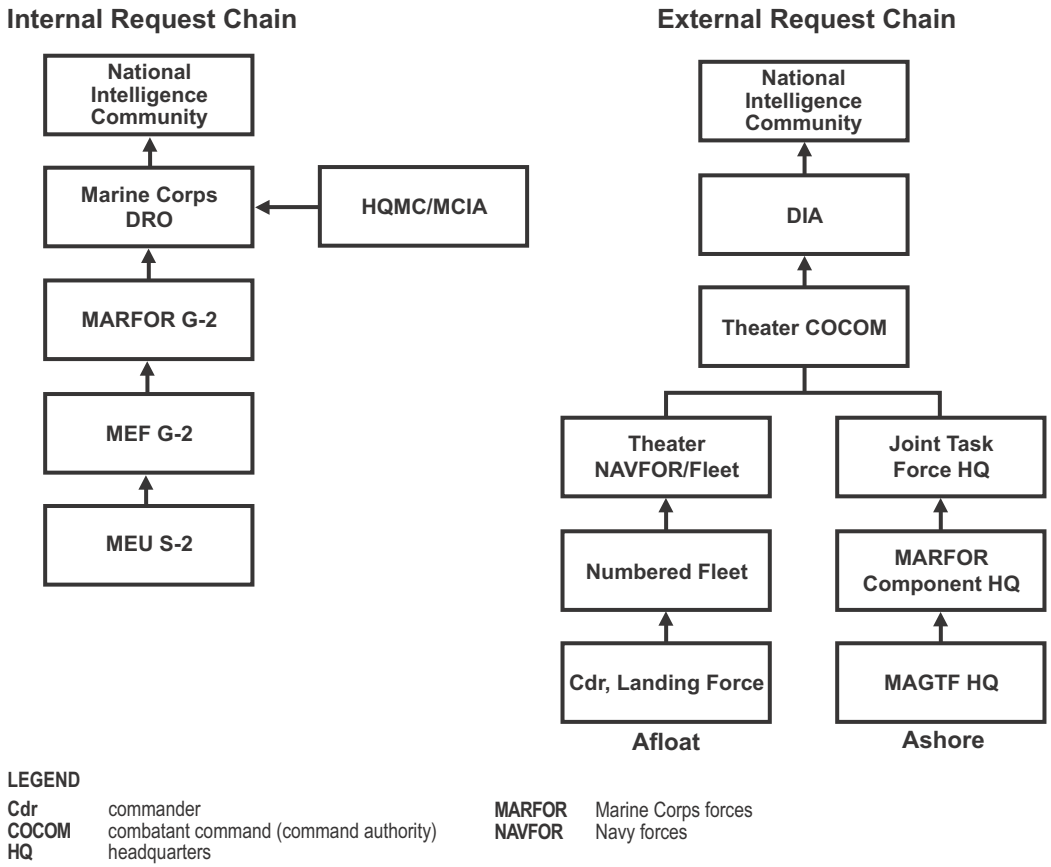

Figure 5-7. Requesting Imagery and Imagery Intelligence Support.

meaningful knowledge that can be used for decisionmaking. Exploitation involves the evaluation, interpretation, integration, analysis, and synthesis of all information that is relevant to a particular intelligence requirement in order to answer the question(s) that have been asked.

Imagery Derived Products. Imagery derived products are secondary products that can be used to facilitate disclosure and release to coalition partners. They are useful for a variety of planning and decisionmaking activities. Several of the most commonly requested products include the following:

- Beach studies.
- HLZ studies.
- Raid studies.

Imagery Intelligence Text Products. Imagery intelligence text products are selected to meet the specific needs of the commander. Appendix F provides the format and instructions for completing the basic IMINT reports described in the following subparagraphs.

Reconnaissance Exploitation Report. The RECCEXREP is used to report the results from the first rapid analysis of imagery, including the debriefing of the aircrew when possible. It addresses the targets requested in the original imagery collection mission tasking, normally with each target addressed separately. It is prepared by intelligence personnel, such as IIP, MAW, or MLG, based on input

from the supporting collecting unit's intelligence section. The report is then disseminated according to the dissemination plan. The SOP designates the specified time limit in which the RECCEXREP must be completed and disseminated.

Initial Photo Interpretation Report. The IPIR provides information regarding tasked imagery collection missions not previously reported (e.g., in the RECCEXREP), when extensive or detailed data from a systematic review of the imagery is required, or when the rapid response required by the RECCEXREP would be hindered by the format, size, or quality of the imagery involved. It also is prepared by the IIP—with input from the supporting collecting unit's intelligence section—and disseminated in accordance with the dissemination plan. The timeline for completing this report is in accordance with the unit SOP.

Supplemental Photographic Interpretation Report. The SUPIR provides information not previously included in a RECCEXREP or IPIR. It reports on significant targets covered by the mission and other required supplemental data. It is prepared by intelligence personnel (e.g., IIP, MAW, MLG) based on input from the supporting collecting unit's intelligence section. The report is then disseminated in accordance with the dissemination plan. The SOP designates the specified time limit in which the SUPIR must be completed and disseminated.

SALUTE Report. The standard SALUTE format is used to report any known or suspected enemy activity. It may also be used to report any characteristics of the AO that affect mission accomplishment. The SALUTE report may be used by a VMU, ground reconnaissance unit, aircrew, or other personnel to report key information obtained during ongoing imagery collection operations. It will be disseminated in accordance with the dissemination plan, generally from the collector to the SARC or directly from the collector to other supported units.

Imagery Intelligence Support to Other All-Source Intelligence Products. Imagery alone will provide useful intelligence to commanders and planners (see app. C). However, intelligence requirements usually will be satisfied more effectively and in greater detail via the complementary combination of an image and supporting IMINT or all-source intelligence products. Review appendix H for an appreciation of the greater intelligence value of a complementary imagery/intelligence report product, vice simply an image product. Target analysis and target material production are examples of such support.

Target Analysis. Generally, the imagery analyst's first responsibility is the detection and accurate identification of areas and activities for situation development and support to targeting. Target detection begins with either general or specific search modes.

General search is undertaken in response to requests for broad area intelligence and usually involves the analytical examination of the entire image. Such searches should be kept to a minimum.

Specific search is undertaken in response to an intelligence requirement that requires point, strip, or route reconnaissance imagery. Its scope and objectives are more limited than general search. Target identification consists of the interpretation of visual cues or distinctive features of targets/objects detected during collection. The distinctive features are analyzed using the six Ss: size, shape, shadow, shade, surroundings, and signal strength. The depth and scope of the analysis is

highly dependent upon the purpose of the analysis and the time constraints of the associated intelligence requirement. Target identification may include the following:

- Determining the OOB and BDAs of threat units and systems at different echelons.
- Identifying both equipment and its intended use by the threat forces.
- Determining the purpose and composition of ports, harbors, waterways, airfields, roadways, railways, and installations.
- Detecting and identifying non-threat forces and equipment and sensitive targets (e.g., religious facilities).

Target Material Production. In accordance with Chairman of the Joint Chiefs of Staff Instruction (CJCSI) 3505.01B, *Target Coordinate Mensuration Certification and Program Accreditation*, a number of imagery analysis specialists at each MEF, the MCIA, and other locations must be certified under an NGA-accredited program to perform precise point mensuration in support of coordinates-seeking weapons and other precision-guided munitions. During fiscal year 2012, III MEF and the MCIA became the first organizations to be certified in precise point mensuration. During fiscal year 2015, II MEF became certified through the Air Force Precise Point Positioning Program (AFP4). I MEF will be certified during fiscal years 2016, with full program implementation planned for fiscal year 2016.

See appendix I for information on target folders and IMINT support to these activities.

Dissemination and Reporting. Imagery intelligence dissemination planning and management involves establishing dissemination priorities, stipulating dissemination and reporting criteria, selecting dissemination means, and monitoring the flow of IMINT reporting. The goal of this process is to deliver IMINT products to the appropriate user in the proper format at the right time, while preventing the dissemination of irrelevant products and avoiding information overload. The following subparagraphs address the most common considerations for intelligence dissemination planners when developing IMINT dissemination plans.

Identify Dissemination Requirements. When identifying requirements, the four Ws—who, where, what, and when—are a good start for determining the broad scope of dissemination needs.

Who. Commander preferences, standing theater OPLAN/concept plans (CONPLANs), type mission analyses, unit SOPs, TTP, playbooks, and previous post-exercise analyses and lessons learned reports are all key sources for identifying organizations, units, and other elements to which the intelligence section must disseminate imagery and IMINT. Identifying and grouping by common imagery and IMINT product requirements by typical command relationship/task organization provides the operational perspective to begin dissemination planning. *Who* receives this imagery can either be internal or subordinate elements and units.

Internal MEF/MAGTF headquarters include a current operations center, future operations center, tactical command echelon (when deployed), force fires coordination center, rear area operations center (when established), civil-military operations center (when established). The subordinate elements and units include intelligence sections of the ground combat element, ACE, and LCE; other MAGTFs and independent task forces; organic/attached/direct support intelligence and

reconnaissance units over which the MEF retains operational control (via either the SARC, other G-2 sections, geospatial support team, and/or direct to the intelligence/reconnaissance units' command posts); and other C2 nodes and facilities, when required (e.g., DASC, enemy prisoners of war compound, rear area operations center, and/or airfield arrival control group).

Where. Generally, the answer to the *where* question will be the location of each identified *who*. However, command relationships, the specific operational phase, task organization, or other factors may identify additional answers to *where* requirements are to be disseminated.

What. With the above information in hand, dissemination planners seek answers to the *what* of each requirement. Here, planners strive to establish or anticipate what type intelligence support (e.g., finished intelligence, particular formats) each *who* typically requires to support his planning and decisionmaking needs. As with the *who* determinations, commander preferences, standing theater OPLAN/CONPLANs, type mission analyses, unit SOPs, TTP and playbooks, and previous post-exercise analyses and lessons learned reports will provide the dissemination SOP foundation and isolate the necessary information. Additionally, planners' research should encompass how differing intelligence resource task organizations affect such requirements and to how they historically have been combined to satisfy the *who* requirements. Cross-referencing the *who* and *what* answers with the following groupings completes this step:

- Typical standalone imagery and IMINT products and IMINT support to all-source intelligence products.
- Alarm intelligence support (e.g., I&W reports, time-sensitive target of opportunity reporting).
- Preferred level(s) of classified information that the *who* desires (further subdivided into what they require access to and what they can actually retain on hand).

When. The final dissemination planning information requirement is to determine to which organizations, units, and other elements (*who*) the intelligence section must disseminate imagery and IMINT or to define the stated *when*. The same sources used to research the previous Ws likewise are recommended for acquiring initial *when* answers and baseline planning criteria. However, this factor is arguably the most variable during tactical operations. Key planning considerations include the following:

- Nature of the requirement (e.g., is it a PIR or in support of another functional information requirement?).
- Rapidly assessing the feasibility of satisfying the decisionmaker's or planner's stated latest time intelligence is of value (LTIOV): Is intelligence already on-hand? Can organic assets acquire or produce needed intelligence? Will external support be needed?
- Communications and networks transmission requirements to support the desired format for the *who* (e.g., voice, text, digital, bulk delivery).
- Capabilities/current status of MAGTF CIS.

Develop Dissemination Plan. Once the four Ws have been completed, the answers can be translated into an IMINT dissemination plan. Imagery intelligence personnel must maintain close coordination with all G-2/S-2 officers, G-3/S-3 planners, and pertinent intelligence personnel at higher, adjacent, supporting, and subordinate organizations.

Design and Coordinate Architecture. The architecture should be designed schematically so that it depicts organizations, type intelligence systems, and CIS connectivity among the forces' (i.e., MAGTF, national, theater) intelligence collectors/producers and the supported decisionmakers/planners. Since planned architectures must incorporate sufficient flexibility to adjust quickly to changing tactical circumstances, it must depict both primary and alternate pipeline and alarm channels and the demand-pull and supply-push methodologies. The large data communications bandwidths associated with imagery dissemination require close planning and coordination between MAGTF intelligence and CIS planners. See appendix J for additional technical information on NITF compression that is useful when designing and coordinating CIS support to IMINT dissemination.

Establish Imagery Intelligence Dissemination Procedures. If intelligence dissemination is to be effective, comprehensive, MAGTF-wide integrated operations—CIS—intelligence procedures are mandatory. The answers to the four Ws will form the foundation on which the MEF's intelligence dissemination architecture and operations can be built.

Allocate or Obtain Resources. The G-2/S-2, in concert with the unit's CIS officer and G-3/S-3, should allocate available resources to accommodate dissemination of the requested IMINT. If resources do not exist to transmit the required information, a request for augmentation from higher headquarters or assistance from lateral units should be initiated immediately. It may be necessary to arrange for the delivery of intelligence directly from the producer to the requester if means are in place.

Coordinate. Once IMINT requirements have been identified and the initial plans developed, planners should develop and coordinate detailed dissemination plans.

Monitor Execution. Following the dissemination of imagery or IMINT products to the requester, it is important to evaluate the flow of information to determine whether or not the user is satisfied with the quantity and quality of intelligence and to ensure that preplanned filters are eliminating circular reporting. Frequent checks with the requestor can ensure intelligence utilization and preclude unanticipated demands on the G-2/S-2 staff.

Imagery Intelligence Utilization. The specific utilization of IMINT is based upon the CONOPS and the imagery application being employed. Commanders, G-2/S-2s, and G-3/S-3s must evaluate IMINT products and reports continuously for timeliness, usefulness, overall quality, and responsiveness to stated PIRs and intelligence requirements. Additionally, evaluators should provide feedback to the MAGTF G-2/S-2 and IMINT planners to improve future IMINT operations.

Imagery Intelligence Operations Appendix. Guidance for conducting IMINT operations comes from many sources. The DIA and the NGA issue policies, direction, guidance, and instructions regarding compliance with national IMINT standards, architectures, and request procedures. Deployed MAGTFs may also need to reference pertinent combatant, joint force, and fleet orders, guidance, and IMINT. Tactics, techniques, and procedures are necessary to identify unique operating concepts, methodologies, support procedures, and formats. Marine IMINT plans and orders are prepared by the G-2/S-2 (under the staff lead of the ISC and with the assistance of the other G-2 section and intelligence staff officers and commanders) and the commanding officers/OICs of the supporting IMINT units. The MAGTF IMINT plans and orders appear as appendix 7

of the intelligence annex of the MAGTF OPLAN or OPORD and will focus on internal MAGTF IMINT requirements, operations, and TTP.

Appendix 7 (Imagery Intelligence) to Annex B (Intelligence) to an OPLAN or OPORD will provide detailed planning and direction for conducting MAGTF IMINT operations. The ISC is responsible for its development. It should be prepared consistently with the format outlined in the Joint Operation Planning and Execution System, tailored as necessary to remain consistent with the situation and the particular needs of the MAGTF (see app. K for a sample IMINT operations appendix format). The IMINT operations appendix should include friendly IMINT forces to be used, and the following:

- Personnel augmentation requirements.
- IMINT units of adjacent or other theater forces and support expected.
- Joint force maritime component commander and naval task force/amphibious force IMINT elements that provide support to the landing force in amphibious operations.
- Pertinent IMINT capabilities and support from the JTF headquarters, combatant command's JIOC, and other component commanders/task forces within JTF operations.
- Planned arrangement and employment of external IMINT support, including special collection, production, dissemination, and CIS.
- Establishment of coordinating instructions for the planning and control of IMINT operations, including the technical support expected from higher headquarters.
- Tasking of MAGTF IMINT elements.
- IMINT production, priorities, and plans.
- IMINT dissemination priorities and plans, including CIS support to the MAGTF IMINT effort.
- Equipment/logistic requirements unique to IMINT.

Imagery Intelligence Planning Considerations in Other Portions of Annex B. The following are other portions of annex B (in addition to appendix 7) where IMINT is incorporated:

- Appendix 11 (Intelligence Estimate). The format for the intelligence estimate is found in appendix A of MCWP 2-3, *MAGTF Intelligence Production and Analysis*.
- Appendix 14 (Reconnaissance and Surveillance Plan):
  - Tab C (Unmanned Aircraft System Plan) (see app. L).
  - Tab D (Aerial Imagery Plan) (see app. M).
- Appendix 16 (Intelligence Operations Plan):
  - Tab A (Intelligence Collections Plan). The format for the intelligence collection plan is contained in appendix C of MCWP 2-2, *MAGTF Intelligence Collection*.
  - Tab B (Intelligence Production Plan). The format for this plan is found in MCWP 2-3.
  - Tab C (Intelligence Dissemination Plan). The format for this plan is found in MCWP 2-4, *Marine Air-Ground Task Force Intelligence Dissemination*.

  - Tab D (Intelligence Communications). The format for this tab is found in MCWP 2-4.
  - Tab E (Intelligence Reports). The format for this tab is found in MCWP 2-3.
- Appendix 17 (Support to Survival, Evasion, Resistance, and Escape—SERE).

CHAPTER 6
TRAINING

The HQMC-Imagery and Geospatial Intelligence Branch—through the Training and Education Command and Marine Corps Intelligence Schools Command—is responsible for implementing and maintaining GEOINT training and education programs. Unit training plans should cover imagery, imagery platforms and sensors, GEOINT data types, post-processing techniques, collections, software, hardware, established and emerging dissemination techniques, production management, and full spectrum geospatial intelligence.

IMAGERY TRAINING

The leadership within each imagery, FMV, and MTI section is responsible to both the Marine Corps Intelligence 0241 occupational field and unit commanding officer for implementing training requirements.

Requirements

Initial training for all IMINT specialists (MOS 0241) is conducted via the tactical imagery analysis course, which is operationally supported by The National Geospatial-Intelligence College located at Fort Belvoir, Virginia. Administrative support for the tactical imagery analysis course is provided by the Marine detachment, Fort Belvoir and Marine Corps Intelligence School. The HQMC-Intelligence Manpower and Training Branch, in conjunction with the occupational field monitor and sponsor, manages student assignments to the operating forces as well as orders to many of the follow-on and advanced training courses.

Training Objectives

Entry-level, intermediate, and advanced training for MAGTF IMINT specialists should include—

- Joint and Marine Corps GEOINT doctrine.
- IC, DOD, and Marine Corps intelligence structure and policies.
- FMV platforms, sensors, and exploitation systems.
- MTI platforms, sensors, and exploitation systems.
- Strategic, theater, organic, and commercial imagery platforms and sensors.
- DOD and Marine Corps imagery exploitation networks, systems, hardware, and software, as well as basic system administration.
- Identification of tactical orders-of-battle.
- Report writing and dissemination systems.
- Support to MAGTF through imagery and IMINT products.

- Exploitation techniques to extract EEIs.
- Tools for discovery, retrieval, and exploitation of imagery and geospatial data.
- Littoral studies in support of amphibious operations.
- LZ studies in support of fixed- and rotary-wing MAGTF assets.
- LOC studies in support of MAGTF assets.
- JP 2-01.3, *Joint Intelligence Preparation of the Operational Environment*.
- Research of intelligence and information.
- GEOINT collaboration with GIS and METOC elements of the MAGTF.

Planning and Employment Training

Planning and employment training is essential to preparing the IMINT specialist for intelligence operations in support of the MAGTF. This training provides—

- Familiarity with the nuances of setting up and configuring equipment for use on classified networks.
- Firsthand experience operating within the systems' constraints created by an expeditionary environment.
- Understanding of when and how to adjust production workflows in order to fulfill the MAGTF commander's intelligence requirements.

System Administration Training. During the tactical imagery analysis course, Marines receive basic system administration training on the TEG FoS. Subsequent formal/managed on-the-job training (MOJT) is needed to ensure analysts have a working knowledge of equipment set up, configuration, utilization, and tear down in austere environments. Each unit should establish its own training cycle to develop and enhance system administration proficiency.

Maintenance Training. Organizational level maintenance of imagery exploitation hardware and software enables the analyst to ensure the unhindered continuation of production workflows and dissemination of completed IMINT studies when systems experience technical difficulties. A significant number of interruptions to the intelligence cycle can be mitigated through user-level familiarity with hardware and software, because the analyst will not need to consult maintenance echelons for assistance. User-level troubleshooting should include a general emphasis on finding alternate means of gathering data and exploiting and disseminating imagery and IMINT studies when primary methods are unavailable.

Database Management Training. Imagery production elements require significant amounts of storage space on local and network servers. The proper management of these storage elements—including directory structure, proper data archive, and production workflows—ensures production cycles are not hindered by server failures and assists in federated production and collaboration through centrally located and properly managed working files.

MAGTF Training

Imagery and IMINT production is incorporated into all MAGTF training. During training exercises, imagery operations should be conducted under a variety of C2 support relationships to improve organizational and employment flexibility. Repeated exposure to imagery capabilities

and employment strategies will enhance the MAGTF's ability to use imagery and IMINT effectively to increase situational awareness and shape operations.

Command Post Exercise/Staff Exercise. The production and use of imagery should be included in every exercise. Training exercises should emphasize the planning of imagery support requirements and production procedures, the dissemination of imagery within MAGTF Marine Corps enterprise network systems, and the use of imagery within the MCPP. The unit intelligence officer should use the planning cycle and develop a realistic imagery production plan. Imagery intelligence analysts should be assigned to the exercise control group in order to validate the planning and production plan and to simulate the dissemination of mission-specific data from national and theater production facilities.

Field Training Exercise. Field training exercises may be used to introduce IMINT analysts to exploitation procedures within the MAGTF IOC. Additionally, a field training exercise provides an operational context in which to integrate, intensify, produce, and disseminate tailored mission-specific data sets in support of C2, intelligence, fire support, aviation, logistic, and maneuver operations. The imagery section should coordinate with staffs and units at all echelons of command. Interaction helps to increase the supported organization's understanding of imagery in general and the capabilities afforded by imagery and IMINT.

TRAINING COURSES

Basic- and advanced-level imagery training programs are available at National Geospatial-Intelligence Agency College. Alternative education imagery programs include correspondence courses, distance courses, and contractor or vendor supported training.

Basic-Level: Tactical Imagery Analysis Course

Active duty students in the tactical imagery analysis course are traditionally sergeants or senior corporals. Reservists are typically privates through sergeants. The tactical imagery analysis course is divided into 10 annexes and spans 91 training days (approximately 5 months). Each annex includes multiple graded events and ends with a comprehensive phase completion exercise during which students employ all skills taught within that annex as follows:

- Annex A: information assurance, classification procedures, intelligence doctrine, operations, maps/charts, intelligence writing, and impromptu briefing.
- Annex B: principles of imagery interpretation, sensor phenomenology, imagery platforms, the ATO, and collections.
- Annex C: identification of orders of battle and facilities.
- Annex D: research techniques and tools, use of software for production, symbology, and cross-referencing geographic locations between various data sources.
- Annex E: production techniques for extracting, analyzing, and annotating completed intelligence studies.
- Annex F: an introduction to full spectrum GEOINT and critical thinking.

- Annex G: dissemination methods.
- Annex H: imagery reports and briefs.
- Annex I: setup, basic systems administration, and teardown of the current imagery exploitation workstation.
- Annex J: the capstone exercise to familiarize the students with operating in a MAGTF IOC.

Intermediate- and Advanced-Level Training

Intermediate- and advanced-level training is available in various skill areas by multiple government and nongovernment entities. Unit training managers should determine the most effective method of training for ensuring that IMINT analysts are properly prepared to meet mission requirements.

Government and Nongovernment Training Sources. The following list contains government and nongovernment training sources:

- Federal agencies.
- DOD agencies.
- Services.
- Corporations.
- Base education centers.
- Colleges and universities.

Delivery Methods for Training. The following list contains delivery methods for training:

- Resident courses/formal schools.
- Primer courses.
- Mobile training teams.
- Computer-based training.
- Web-based training.
- Distance courses.
- MOJT.

Training Considerations. Since the majority of follow-on training is provided by organizations outside of the Marine Corps, leadership of imagery sections must ensure that their analysts are able to integrate these tactics and techniques into the MAGTF mission using existing methods while following established or emerging Marine Corps intelligence doctrine and operational concepts. Training managers are also responsible for ensuring that the knowledge and experience gained through training supports the unit mission and the Marine Corps mission by considering the following:

- Special hardware or software to make use of advanced exploitation techniques.
- Classification and releasability.

Training Entities. Creative utilization of available training resources ensures the individual analyst, unit, and occupational field are prepared to support the MAGTF mission. Funding and unit mission should be carefully scrutinized and training managers should ensure training dollars are spent on the most qualified and deserving analysts. Training is available from the following resources:

- National Geospatial-Intelligence Agency College.
- Joint Intelligence Virtual University.
- National Defense Intelligence College.
- Software vendors.
- Hardware vendors.

Follow-On Training Subject Areas

The subject areas discussed in the following subparagraphs should be considered essential to the continued development of individual analysts and MOS 0241 by training managers.

Marine Corps and Joint Intelligence Doctrine. Doctrine provides analysts with an established reference for joint and MAGTF procedures and operations; moreover, knowledge of doctrine prepares the analyst to anticipate the MAGTF commander's needs. This doctrine facilitates greater speed and focus of analytical effort and, when coupled with knowledge of the enemy, facilitates predictive analysis.

Intelligence Writing. The ability to communicate the numerous pieces of information and intelligence on written reports is a skill needed by all intelligence analysts. Completed imagery and IMINT studies can often be difficult to disseminate due to network constraints and may need to be supplemented by textual reports.

Imagery and Imagery Intelligence Production. Repetition provides analysts with an intimate working knowledge of production techniques, procedures, timelines, software operation, and hardware operation; builds analytical efficiency; and equips analysts with the necessary skills to operate autonomously. Unit training events, MOJT, exercises, and real world production scenarios should be utilized to develop the analytical processes that consistently produce the necessary results, as well as develop the analytical mind that can effectively advise the MAGTF commander on proper utilization of imagery production assets.

Imagery, Imagery Intelligence, and Geospatial Intelligence Data. Imagery intelligence analysts need a thorough knowledge of the differences in data types, uses, and special handling issues. This knowledge enables analysts to integrate other data sets quickly into production workflows and generate IMINT and GEOINT products and reports in support of operations. Analysts should be familiar with software operating files, hardware operating files, imagery files, and the differences between each; post-processed data file types; and any other files they will commonly utilize in accomplishment of the mission.

Imagery, Imagery Intelligence, and Geospatial Intelligence Databases. The proper storage of both raw data and finished intelligence products is essential. Analysts must be able to configure servers

properly for use on exploitation networks, manually and semi-manually store information and IMINT studies, and archive data.

Spectral Exploitation and Spectral Systems. Basic and advanced training in analysis of spectral data is designed to provide students with a deeper understanding of spectral imagery processing as well as literal and nonliteral spectral imagery analysis techniques. Multispectral and hyperspectral imagery exploitation and processing techniques should be covered. Familiarity with essential software and plug-ins for exploitation are also essential to exploitation.

Commercial Imagery. Marines must understand proper copyright procedures, as well as how licensing affects the dissemination of commercial imagery and data outside of licensed users. This knowledge impacts the ability of the Marine Corps to do the following:

- Share data with various governments, agencies, nongovernmental organizations, and personnel during MAGTF operations, which can often be hindered by security classifications.
- Research, retrieve, properly exploit, and disseminate commercial data available to DOD entities, which is essential to these operations.

Airborne Imagery. The understanding of strategic, theater, and tactical airborne platforms, sensors, and data, as well as how to gain access to airborne libraries greatly increases the data available to the imagery analyst for exploitation.

Motion Imagery. Reliance on FMV for persistent ISR has continued to grow within the Marine Corps and DOD. Knowledge of UASs and their associated systems provides analysts with the necessary skills to manage the tasking, processing, exploitation, and dissemination process.

Moving Target Indicator. Training in the use of MTI data and systems to support the MAGTF is accomplished via formal schooling. Basic analysts should possess familiarity with raw MTI data, exploitation hardware and software, completed products, and processes in order to facilitate collaboration.

Synthetic Aperture Radar. Training in the use of MTI data and systems to support the MAGTF is accomplished via intermediate training based at a government facility or provided directly to the unit. The MTI operator training course will supply MOSs 0231 and 0241 with MTI fundamentals, hardware and software setup and configuration, exploitation tools, product development, and various MTI support missions.

Advanced Phenomenologies and Imagery Techniques. Formal training in the software, techniques, and releasability of thermal infrared imagery, polarimetric imagery, and overhead persistent infrared is essential to ensuring analysts can seamlessly integrate solutions into MAGTF intelligence problems. Familiarity with essential software and plug-ins for exploitation is also essential to exploitation.

Foreign Disclosure. Marines must be familiar with foreign disclosure procedures. Military information is a national security asset that must be conserved and protected. It may be shared with foreign representatives only when there is a clearly defined advantage to the United States.

Only designated foreign disclosure officers may approve of the disclosure of classified and controlled unclassified military information to foreign representatives. The Secretary of the Navy Manual, *Department of the Navy Foreign Disclosure Manual*, and MCO 5510.20B, *Disclosure of Military Information to Foreign Governments and Interests*, are two of the many references which should be reviewed and understood.

Imagery Classification Marking. While it is important that the public be informed concerning the activities of its government, certain information concerning the national defense and foreign relations must be protected against unauthorized disclosure. This information is called national security information and is classified if its disclosure might cause damage to the nation's security. Marines must be aware of the rules regarding classification of the imagery products they produce as well as those produced by other courses. Executive Order 13526, *Classified National Security Information*, and Executive Order 12951, *Release of Imagery Acquired by Space-Based National Intelligence Reconnaissance Systems*, are just two of the references on classified material.

Full Spectrum Geospatial Intelligence. Full spectrum geospatial intelligence, also known as imagery-derived MASINT, includes all types of information technically derived from the processing, exploitation, and nonliteral analysis (including integration or fusion) of spectral, spatial, temporal, radiometric, phase history, and polarimetric data. These types of data can be collected on both stationary and moving targets by electro-optical, infrared, radar, and related sensor programs (both active and passive).

APPENDIX A
IMAGING SENSORS

This appendix describes the basic capabilities and limitations of EO, radar, and infrared imagery sensors.

OPTICAL SENSORS

Optical sensors detect and record electromagnetic radiation within the visible light and near-infrared portions of the electromagnetic spectrum. The operating principles are the same as those of a common digital camera. There are three types of optical imaging systems: vertical, oblique, and panoramic.

Vertical

The optical axis of the sensor is approximately perpendicular to the surface of the earth (see fig. A-1). Vertical imagery is ideal for performing terrain analysis, beach studies, and HLZ studies.

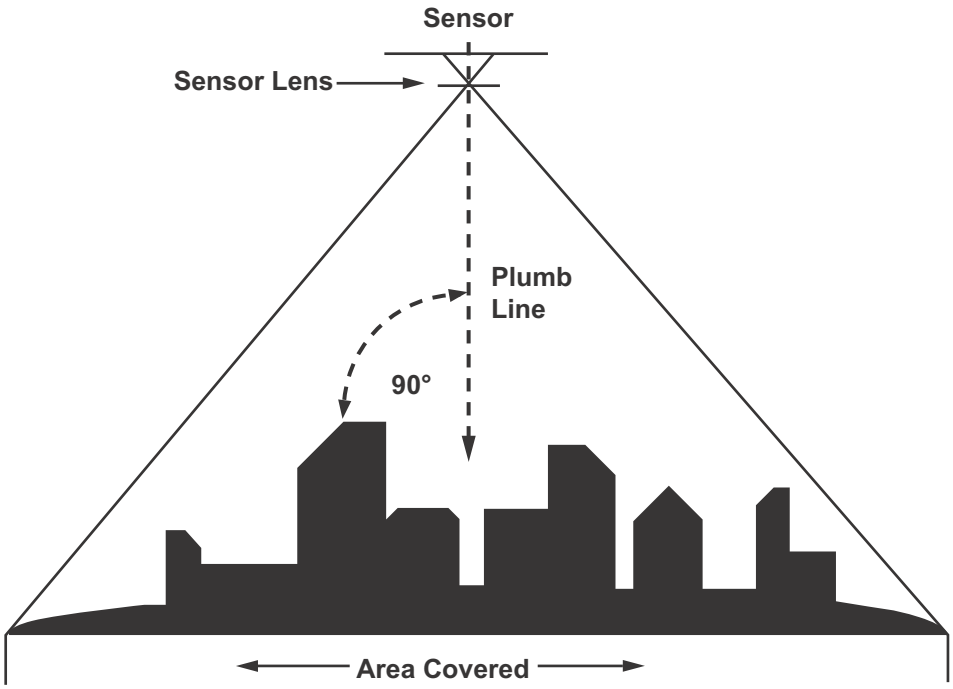

Figure A-1. Vertical Optical Sensor and Ground Relationship.

Oblique

Oblique imagery is obtained by imaging the ground at an angle to the vertical and requires oblique metrics. The optical axis of the sensor is intentionally directed between the horizontal and the vertical. This axis can provide left or right oblique coverage and is ideal for observation at canopy baseline as well.

There are two standard types of oblique imagery: high and low. High oblique imagery will include the horizon (see fig. A-2), while low oblique imagery will not (see fig. A-3). Because of the angle, high oblique imagery covers a larger area than low oblique. Oblique imagery is referred to as left or right oblique or forward looking, based on the look angle in relation to the platform.

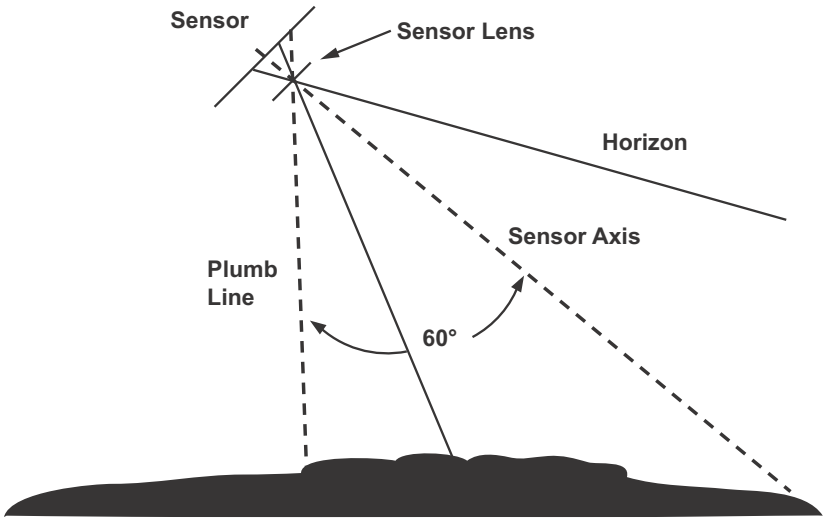

Figure A-2. High Oblique Sensor to Ground Relationship.

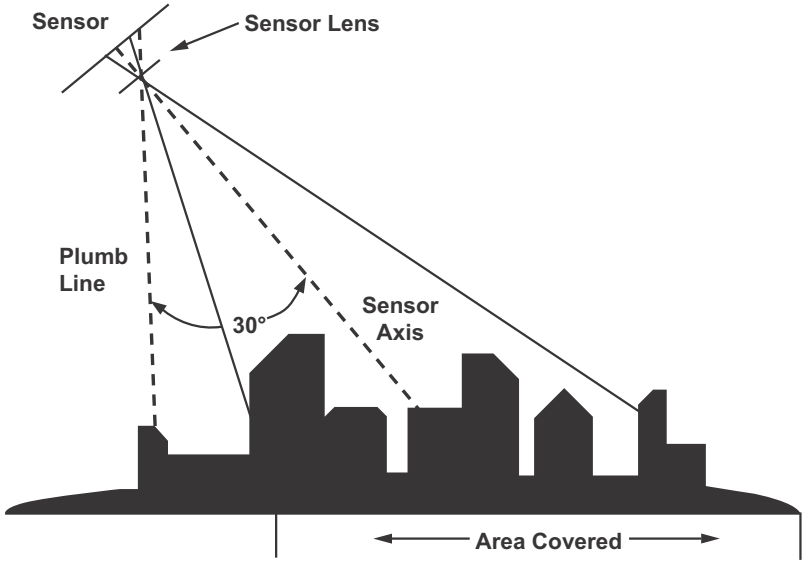

Figure A-3. Low Oblique Sensor to Ground Relationship.

Panoramic

Panoramic imagery is taken with a special sensor that scans a wide area. The optical axis of the sensor uses a system of optics that can scan an area from 0 to 180 degrees. There are two types of panoramic imagery: low and high. Low panoramic imagery is taken at low altitudes and scans a wide angle that includes the horizon at either side of the aircraft flight path (see fig. A-4).

High panoramic imagery is taken at high altitudes with a narrow scan angle (see fig. A-5). The horizon is not normally visible on high panoramic imagery.

In only one pass over the target area, panoramic photography provides coverage of large areas of terrain on both sides of the aircraft flight path. Although it provides both vertical and oblique views of the image area, it is the most difficult and time-consuming photography to analyze and measure due to the distortion of the recorded image. Table A-1, on page A-4, summarizes both the advantages and disadvantages of each type of imaging system.

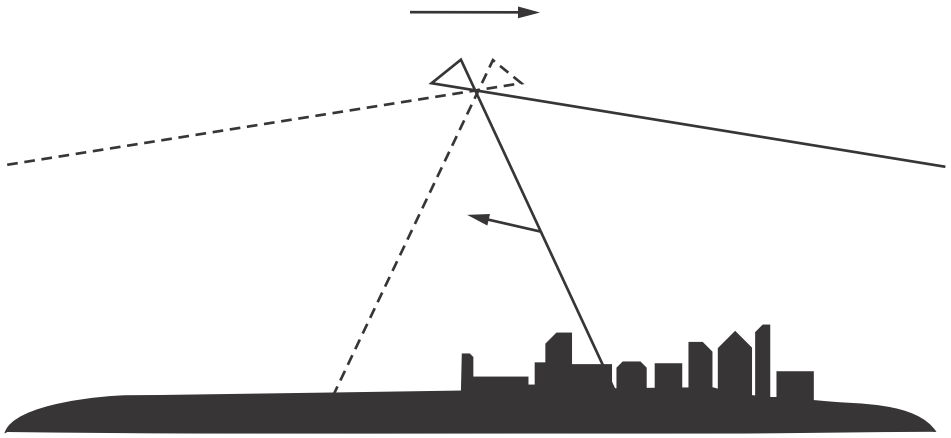

Figure A-4. Low Panoramic Imagery.

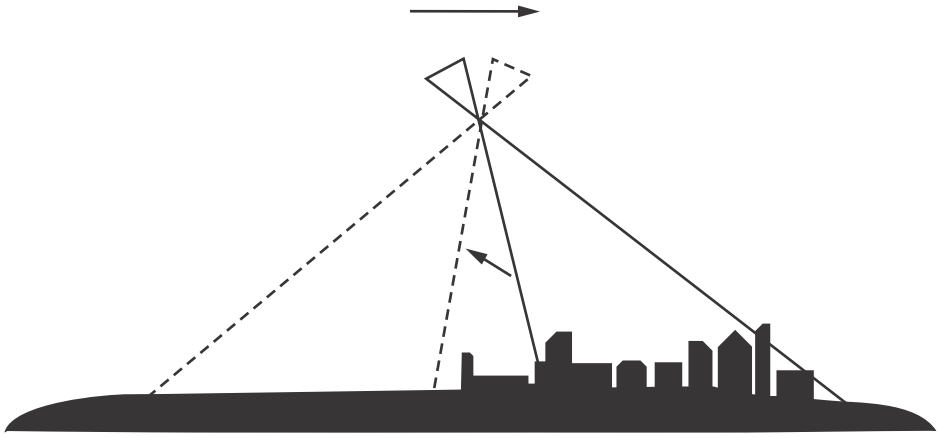

Figure A-5. High Panoramic Imagery.

Table A-1. Optical Sensor Advantages and Disadvantage.

Sensor System	Advantages	Disadvantages
Vertical	Provides fairly constant scale Can construct mosaics Obtains accurate measurements Allows stereographic viewing Allows for accurate interpretation	Flight path is directly over the target Covered objects cannot be viewed View angle is unnatural It is susceptible to flight restrictions
Oblique	Provides large area coverage Provides natural view Offsets flight path from target Allows for covered objects viewing, due to angle	Terrain masking Scale varies Measurements are difficult
Panoramic	Provides large area coverage Satisfies both vertical and oblique mission requirements	Scale varies Platform has limited standoff capability Measurements are difficult

The capabilities of optical sensors are as follows:

- They produce high-quality photographs (good resolution).
- They are a passive system, which cannot be detected or jammed.
- Their sensors offer flexibility.

The limitations of optical sensors are as follows:

- They require a light source.
- They are hampered during periods of reduced visibility.
- They are LOS dependent.

Radar

Radar is an active sensing technique that detects and records differences in reflected electromagnetic energy. The capabilities of radar are as follows:

- It can be used for day and night operations.
- It provides all-weather capability.
- It provides constant scale and resolution.
- It provides standoff capability.

The limitations of radar are as follows:

- It provides poor resolution.
- It is an active system, which can be detected or jammed.
- It is LOS dependent.

Infrared

Infrared sensors detect and record electromagnetic radiation that is emitted from a given target surface in the infrared portion of the electromagnetic spectrum. The capabilities of infrared are as follows:

- It can be used for day and night operations.
- It is a passive system, which cannot be detected or jammed.
- It detects camouflaged equipment and activity.

The limitations of infrared are as follows:

- It offers poor resolution, when compared to EO imagery.
- It is susceptible to adversary deception.
- It is not all-weather; it is hampered by such disturbances as rain, snow, or hail.
- It is LOS dependent.

APPENDIX B
IMAGERY AND SUPPORTING INTELLIGENCE REPORTS

This appendix provides examples of MAGTF intelligence products that are derived from the fusion of available imagery. Such products support IMINT and all-source intelligence reports, tactical planning, and decisionmaking. The examples and formulas in this appendix are provided to aid in the preparation of imagery and supporting intelligence products and studies. They are meant to be used as general guides for these types of products and not to replace or supersede any products being developed in accordance with local SOPs. Additionally, the MCIA maintains a set of instructions distributed across the Marine Corps for imagery analysts including all of the material provided herein.

Examples of imagery products included in this publication are as follow:

- Image and supporting intelligence report for the military operations on urbanized terrain (MOUT) facility, Camp Lejeune, North Carolina.
- Image and supporting intelligence report for the Marine Corps Air Station, New River, North Carolina.
- Image and supporting intelligence report for HLZ Vulture, Camp Lejeune, North Carolina. Image and supporting intelligence report for Onslow Beach North, Camp Lejeune, North Carolina.
- Image and supporting intelligence report for Kin Red Beach, Okinawa, Japan.

Legend for Appendix B:
DMA–Defense Mapping Agency
GEO–geographic coordinate
JLOTS–joint logistics over-the-shore
LCAC –landing craft air cushion
MIM–military installation map
MPF–maritime prepositioning force
NAD–North American datum
nm–nautical miles
No–number
OP-2–Outpost 2
RO/RO–roll on/roll off
STD–standard
WGS–World Geodetic System

Urban Imagery Product Example: Image and Supporting Intelligence Report for the Military Operations on Urbanized Terrain Facility, Camp Lejeune, North Carolina

Center Coordinates
UTM: 18STD93843838
GEO: 343959N0771459W

Size
Length: 1,025 ft (312 m)
Width: 800 ft (244 m)

Surface Material
Silty sand
Gravel

Map Reference
Sheet: Camp Lejeune MIM
Series: V742S
Edition: 2-DMA
Datum: NAD 83/WGS 84

Remarks
The MOUT facility is located approximately 2 km east-north-east of OP-2. The primary use of the MOUT facility is combat training in an urban environment. The MOUT facility consists of 31 buildings of varying sizes and shapes. Roof types are a mixture of garbled and flat. The facility is surrounded by trees of varying heights. The exit from the MOUT facility is a loose surface road which provides access to Lyman Road.

Note: All building measurements are listed as length x width x height.

Exits

Anno. #	Type	True Bearing	Distance	Width	Surface Material
E1	Road, loose-surfaced	146	169.8 m (557 ft)	7.6 m (25 ft)	Earth and sand
E2	Road, loose-surfaced	175	163.1 m (535 ft)	6.4 m (21 ft)	Earth and sand
E3	Road, loose-surfaced	181	165.0 m (541 ft)	6.7 m (22 ft)	Earth and sand
E4	Road, loose-surfaced	281	204.3 m (670 ft)	5.6 m (18 ft)	Earth and sand

Descriptions of the buildings shown in figure B-1 are as follows:

B1. Three-story, 120 ft x 58 ft x 37 ft (37 m x 18 m x 11 m), T-shaped building (hotel), with near-flat roof. A helicopter landing point (LP) is painted with non-reflective white airfield markings and consists of a concrete slab roof. The helicopter landing point is 38 ft x 33 ft (12 m x 10 m). The building's roof is outlined by a parapet with scuppers and a gutter. (A scupper is an opening in the wall of a building through which water can drain). The front portion of the roof consists of tube trusses or transverse monitors. Grappling and rappelling anchors are located at points throughout the roof.

B2. Two-story, 72 ft x 60 ft x 31 ft (22 m x 18 m x 9 m), square-shaped building (city hall), consisting of a near-flat roof outlined by a parapet; however, the northwest corner is lower than the main roof. The roof has grappling and rappelling anchors at points throughout the roof. The corner of the roof is open to a crawl space.

B3, B4. Two-story, crescent-shaped buildings (apartments), with an outer edge measuring 121 ft x 60 ft x 31 ft (37 m x 18 m x 9 m), and an inner edge measuring 84 ft x 60 ft x 31 ft (26 m x 18 m x 9 m), outlined by a parapet with scuppers. Grappling and rappelling anchors are located at points throughout the roofs. The roofs are near flat with a ridge dissecting each building, and a near-flat roof dissected by a ridge separates the two buildings.

B5. Three-story, 72 ft x 36 ft x 38 ft (22 m x 11 m x 12 m), quasi-rectangular-shaped building (office). Grappling and rappelling anchors located on the southeast and northwest sides of roof. The southern end of the building is two stories, 23 ft (7 m) high. An elevator shaft is located in the center of the roof.

B6. Two-story, 44 ft x 36 ft x 25 ft (13 m x 11 m x 8 m), L-shaped building (office). The northwest portion of the roof is a concrete slab.

B7. Rectangular, 121 ft x 73 ft x 77 ft (37 x 22 x 23 m), T-shaped building with dormers (church) with a gable roof made of asphalt and fiberglass shingles. The height of the main building is 48 ft (15 m), the steeple is 29 ft (9 m).

B8. Three-story, 53 ft x 34 ft x 39 ft (16 m x 10 m x 12 m), irregular-shaped building (business/residential) with near-flat roof. Grappling and rappelling anchors are located at points throughout the roof.

B9. Three-story, 50 ft x 47 ft x 39 ft (15 m x 14 m x 12 m), irregular-shaped building (business/residential) with near-flat roof.

B10. Single-story, 128 ft x 46 ft x 18 ft (39 m x 14 m x 5 m), rectangular-shaped building (business/residential) with flat roof.

B11. Two-story, 103 ft x 53 ft x 30 ft (31 m x 16 m x 9 m), rectangular-shaped building (townhouse) that has a gable roof with a dormer. The roof consists of fiberglass shingles reinforced by wooden trusses.

B12. Two-story, 103 ft x 53 ft x 30 ft (31 m x 16 m x 9 m), rectangular-shaped building (townhouse). The front and rear portions of the building's walls are incomplete. It has a gable-roofed dormer with fiberglass shingles and reinforced wooden trusses.

B13, B14. Two-story, 103 ft x 53 ft x 30 ft (31 m x 16 m x 9 m), rectangular-shaped buildings (townhouses) with gable roof and dormers. The roof consists of fiberglass shingles reinforced with wooden trusses.

B15. Two-story, 88 ft x 73 ft x 25 ft (27 m x 22 m x 18 m), irregular-shaped building (school) with near-flat roof built on a 2-inch slab of concrete. Rappelling anchors are located at points throughout the roof. Two fire escape ladders are located on the northeast and southwest sides of the roof.

B16. Two-story, 128 ft x 74 ft x 25 ft (38 m x 23 m x 8 m), irregular-shaped building (gymnasium) with a near flat roof. Fire escape ladders are located on the south side of the building.

B17. Two-story, 43 ft x 36 ft x 26 ft (13 m x 11 m x 8 m), square-shaped building (retail bank) with a near-flat roof. Grappling anchors located at points throughout the roof. Roof access by ladder is located on the northwest corner of the building.

B18. Single-story, 74 ft x 32 ft x 17 ft (23 x 10 x 5 m), quasi-rectangular-shaped building with hipped roofs (service stations).

B19. Single-story, 63 ft x 43 ft x 23 ft (19 m x 13 m x 7 m), rectangular-shaped building (warehouse) with a near-flat roof. The roof consists of standing seam metal on metal purloins. (Purloins are horizontal timbers supporting the rafters of a roof.)

B20. Single-story, 83 ft x 63 ft x 25 ft (25 m x 19 m x 8 m), square-shaped building (warehouse) with a near-flat roof on metal purloins and a mezzanine. (A mezzanine is an intermediate floor between two main floors of a building.)

B21, B22. Single-story, 52 ft x 40 ft x 15 ft (16 m x 12 m x 5 m), T-shaped buildings with basements (residential). The gable-style roof is reinforced with wooden trusses. The chimney height extends 2 ft (.6 m) above the peak of the roof.

B23, B24, B26. Single-story, 52 ft x 40 ft x 15 ft (16 m x 12 m x 5 m), T-shaped buildings (residential) with gable style roof reinforced with wood trusses. Chimney extends 2 ft (.6 m) above peak.

B25. Residential, 52 ft x 40 ft x 15 ft (16 m x 12 m x 5 m), irregular-shaped building with a gable-style roof reinforced with wood trusses.

B27, B28. Single-story, 44 ft x 40 ft x 17 ft (13 m x 12 m x 5 m), T-shaped buildings (residential) with reinforced wooden trusses. The gable roofing consists of fiberglass shingles.

B29, B30. Small, 44 ft x 40 ft x varies (13 m x 12 m x varies), T-shaped buildings, nearly destroyed; may provide some shelter from direct fire.

Airfield Product Example: Image and Supporting Intelligence Report for the Marine Corps Air Station, New River, North Carolina

Center Coordinates

HLZ Shape	HLZ Type	Surface Material	HLZ Size
Irregular	Open Field	Scrub Grass	Length: 1,209 ft (369 m) Width: 215 ft (66 m)

Exits

No.	Type	Distance and Grid Azimuth from HLZ Center	Width
E1	Loose surface road	182 ft (55 m) 280°	20 ft (6 m)

Flight Hazard

No.	Type	Height and Grid Azimuth to HLZ Center
See remarks		

Remarks

The HLZ is located 600 m south of stone bay rifle range. E1 exits the HLZ on the west side extending north on Booker Washington Boulevard to the rifle range or west to range road. The western perimeter of the HLZ has four buildings that may present flight hazards. The HLZ is surrounded on the north, south, and east sides by trees of varying height that may constitute flight hazards to low-flying aircraft. Blowing sand and debris caused by rotor wash may produce flight hazards. Adjacent terrain consists of a dissected plain, vegetated with trees and brush.

Beach Study Example: Image and Supporting Intelligence Report for Onslow Beach North, Camp Lejeune, North Carolina

Sheet: Camp Lejeune MIM
Series: V742S
Edition: 2-DMA
Datum: NAD 83/WGS 84

Left Flank	Beach Center	Right Flank
UTM: 18STD90132636	UTM: 18STD90702680	UTM: 18STD93032730
GEO: 343327N0771714	GEO: 343341N0771636	GEO: 343354N0771633W

Length	Width
Total: 1,393.4 m (4,752 ft) average backshore	Width: 66.4 m (218 ft)
Usable: 1,373.1 m (4,505 ft) visible foreshore	Width: 24.0 m (79 ft)

Surface Material	Trafficability
Nearshore: sand and mud	Personnel: dry—good wet—fair
Foreshore: sand	Wheeled: dry—good wet—fair
Backshore: sand	Tracked: dry—good wet—fair

Tides

Tidal type: diurnal	Average beach gradient: 1:116	Matting recommended: yes
Tidal range: 1.0 m (3 ft)	Firmness: firm when wet	
MFP capable: no; see remarks.	JLOTS capable: no; see remarks.	LCAC offload capable: yes; see remarks.

Location: Onslow Beach North is approximately 13.1 km (7.1 nm) south-southeast of the US Embassy. It is 3.7 km (2.0 nm) east-northeast of HLZ Bluebird and 1.4 km (0.8 nm) east-southeast of HLZ Albatross.

Characteristics remarks: Onslow Beach North is not MPF-capable since there is no MPF-capable port within 92.7 km (50 nm) of the beach. It is not JLOTS-capable due to insufficient beach gradient. It is, however, LCAC offload-capable due to average backshore width of 66.4 m (218 ft). All coordinates provided in this report were derived from the 1:50,000 scale map sheet listed in the reference above. All measurements were derived by MEF imagery analysts from mensurated imagery.

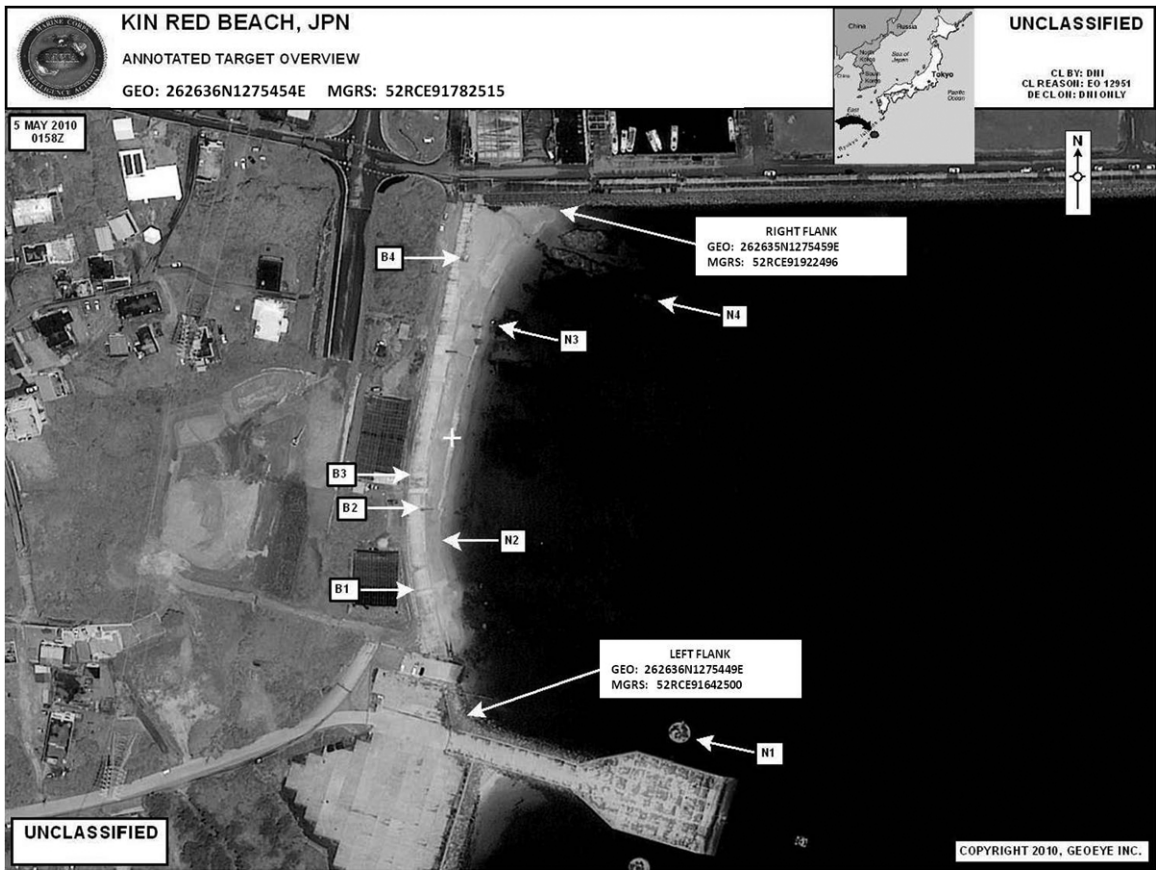
Obstructions

Anno. #	Type	True Bearing	Distance	Length	Width
N1	Pier	225	542.0 m (1,778 ft)	20.3 m (67 ft)	4.5 m (15 ft)

Obstruction remarks: None

Exit remarks: Cross-country to partial cross-country exits are available along the entire beach. These exits are too numerous to list individually. Parallel to the beach is a road that extends 6.3 km (3.4 nm) southwest to New River Inlet and 1.4 km (0.8 nm) northeast to Onslow Beach Road which leads approximately 2.8 km (1.5 nm) north-northeast to Highway 172. There are several buildings and compounds in the hinterland along the road.

Beach Study Example: Image and Supporting Intelligence Report for Kin Red Beach, Okinawa, Japan



Sheet: Kin Red MIM
Series: V742S
Edition: 1-DMA
Datum: NAD 83/WGS

Left Flank	Beach Center	Right Flank
UTM: 52RCE91642500	UTM: 52RCE91782515	UTM: 52RCE91922496
GEO: 262636N1275449E	GEO: 262636N1275454E	GEO: 262635N1275459E

Shape: straight

Length	Width
Total: 274 m (899 ft) average backshore	width: 16.4 m (218 ft)
Usable: 151 m (496 ft) visible foreshore	width: 24.0 m (79 ft)

Surface Material	Trafficability
Nearshore: sand/coral	Personnel: wet—good dry—fair
Foreshore: sand/coral	Wheeled: wet—good dry—fair
Backshore: sand	Tracked: wet—fair dry—poor

Tides

Tidal type: mixed	Average beach gradient: 1:116	Matting recommended: yes
Tidal range: 1.7 m (5.6 ft)	Firmness: firm when wet	

Location and general remarks: Kin Red Beach is located 17.6 km northeast of Kadena Airfield. Four islands obstruct the mouth of Kin Bay. The beach is flanked by a RO/RO pier to the west and a breakwater to the east. There are intermittent streams that cross the beach that could hinder lateral movement during inundation. Personnel exit via cross-country along the entire beach length. The beach is backed by a concrete stepped seawall (B4) that severely restricts tracked vehicle and prevents wheeled vehicle movement. The town of Kin Cho further hinders and channels movement from the beach. Hinterland consists of hills covered with dense vegetation of varying heights, cultivated fields, numerous urban areas and/or tombs.

Obstructions

Anno. #	Type	True Bearing	Distance	Length	Width
N1	Dolphin	226	157 m (515 ft)	3 m (10 ft)	3 m (10 ft)
N2	Coral	250	86 m (282 ft)	18 m (59 ft)	20 m (66 ft)
N3	Coral	090	46 m (150 ft)	32 m (105 ft)	12 m (39 ft)
N4	Coral	113	92 m (302 ft)	40 m (131 ft)	32 m (105 ft)
B1	Coral	261	94 m (308 ft)	8 m (26 ft)	7 m (23 ft)
B2	Coral	270	26 m (85 ft)	14 m (46 ft)	9 m (30 ft)
B3	Coral	077	51 m (167 ft)	16 m (52 ft)	13 m (43 ft)
B4	Seawall	270–070	Varies	270 m (886 ft)	9 m (30 ft)

Obstruction remarks: Obstructions are measured from the beach center to the obstruction.

Exit remarks: See location and general remarks above.

APPENDIX C
IMAGERY INTELLIGENCE
SUPPORT TO INTELLIGENCE STUDIES

Intelligence preparation of the battlespace is the systematic, continuous process of analyzing the threat and environment in a specific geographic area. (Marine Corps Reference Publication 5-12C, *Marine Corps Supplement to the Department of Defense Dictionary of Military and Associated Terms*) It supports commander and staff estimates and decisionmaking. Applying the IPB process helps the commander selectively apply and maximize combat power at critical points in time and space on the battlefield. When viewed within the scope of the entirety of the IPB, imagery plays a small and focused role; however, its role is vital, especially with respect to terrain analysis and mapping tasks. In the following paragraphs, examples and formulas are provided to aid in the preparation of IPB support products and studies. They are meant as general guides for these products and not meant to replace or supersede any products being developed in accordance with local SOPs.

IMAGERY INTELLIGENCE SUPPORT TO DROP ZONE STUDIES

A drop zone (DZ) is a specific area upon which airborne troops (e.g., a radio reconnaissance team), equipment, or supplies are air-dropped. (JP 1-02, *Department of Defense Dictionary of Military and Associated Terms*) Drop zones are preplanned locations that are determined after careful consideration. When evaluating DZs, imagery analysts must consider the following factors:

- Minimum DZ dimensions (length/width computations).
- Maximum slope percentage for DZs is 30 percent.
- Surface and obstacle considerations.
- DZ accessibility and trafficability.
- Easy exit from the DZ.
- Type of aircraft employed.
- Altitude at which air delivery is to be made.
- Types of loads to be delivered.
- Availability of adequate aircraft approach and departure routes.
- Method of airdrop: free drop, high or low velocity.
- Potential approaches and exits.
- Proximity to mission objective.

- Enemy disposition.
- Alternate DZs and LZs.
- Supporting fires (in coordination with the G-3/S-3 and the fire support coordinator).

Drop Zone Length/Width Computations

The request for DZ identification and supporting intelligence usually includes the rate of speed the aircraft will fly over the proposed area and the amount of time required to deliver a load. The imagery analyst (or all-source intelligence analyst) must be informed of the prevailing wind velocity and wind direction, both of which have an impact on the aircraft's ground speed. When the wind velocity at the delivery altitude cannot be determined, the aircraft's air speed should be used as the ground speed. The steps used to compute DZ size are discussed in the following subparagraphs.

Computing Drop Zone Length. The minimum required DZ length (in meters) is computed by multiplying the ground speed of the aircraft (R) (accounting for windspeed) by the time needed to release its cargo (T): L = R x T. The ground speed is computed by multiplying the aircraft speed in knots (S) by .51, which is the conversion factor of knots to meters per second: R = S x .51.

When computing ground speed (R), add tail wind component of wind velocity to aircraft speed (S) or subtract head wind component of wind velocity from aircraft speed (S) (see fig. C-1). Always round up the required DZ length to the nearest meter. For example, if the aircraft speed (S) is 110 kts, head wind is 20 kts, and drop time (T) is 20 seconds, the required length of the DZ (L) is:

L = R x T = S x .51 x T

L = (110 - 20) x .51 x 20 = 918 m

Computing Dropzone Width. The required DZ width depends upon the method/type of airdrop, wind drift, and formation of the aircraft—all of which is usually provided in the request. When it is not specified, the requester must be given the widths of all proposed DZs that also possess the required

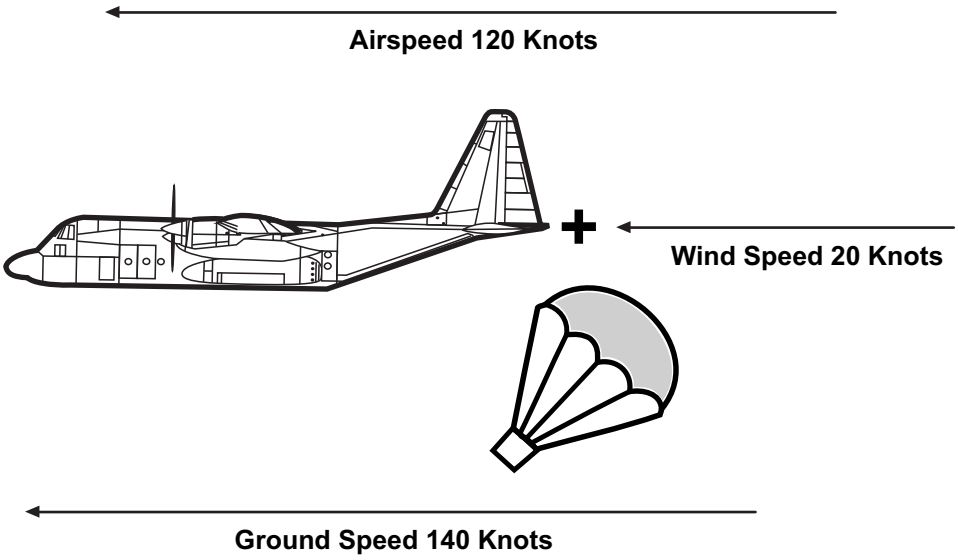


Figure C-1. Prevailing Wind Speed.

length. The wind drift formula—D = K x A x V—is used to determine the minimum required width of a DZ. In this formula, K is a constant that represents the characteristic drift of a certain model parachute. As with the length, the required DZ width is rounded to the nearest meter.

Wind drift has the following factors:

- D = width of DZ (in meters).
- K = 4.1 (constant) for personnel parachutes; 2.6 (constant) for all other parachutes.
- V = velocity of surface wind (in knots).
- A = altitude of the aircraft (in hundreds of feet above ground level).

For example, an aircraft flying at 2,000 ft above ground level (A) is to drop a cargo load with wind speed of 11 kts (V). In this case, G13 cargo parachutes are used (2.6 constant [K]).

D = K x A x V

D = 2.6 x (2,000 ft ÷ 100) x 11

D = 2.6 x 20 x 11 = 572 m

Searching for a Suitable Drop Zone. Now that the required dimensions are known, the imagery analyst searches the imagery (or map if imagery is not available) for suitable DZs. Using a photo interpreter scale or equivalent scale, the imagery analyst measures the potential DZ length on the imagery and then computes the ground distance in meters, rounding down to the nearest meter. The following formulas are used:

- Imagery length: GD = PD x DPRF.
- Map length: GD = MD x DMRF.

The following legend applies to the imagery and map length formulas:

- GD = ground distance (length) (in meters).
- PD = photo distance (if in feet, then multiply by .3048, the conversion factor of feet to meters).
- DPRF = denominator of the photo representative scale factor.
- MD = map distance.
- DMRF = denominator of the map representative scale factor.
- The scale is noted as 1: DPRF or DMRF.

For example, an image has a scale of 1:25,000 (DPRF). Using a scale, the analyst measures a potential DZ to be .06 ft (PD).

GD = PD x DPRF

GD = (.06 x .3048) x 25,000 = 457.2 m = 457 m

The imagery analyst measures the potential DZ width on the imagery (or map if imagery is not available) and then computes the ground distance in meters, rounded down to the nearest meter.

For example, an image has a scale of 1:25,000 (DPRF). Using a scale, the analyst measures a potential DZ to be .04 ft (PD).

GD = PD x DPRF

GD = (.04 x .3048) x 25,000 = 304.8 m = 304 m

In those cases where the plot of the potential DZ is irregular in shape, the lengths and widths will be determined as shown in the sketch in figure C-2. The usable length is measured along a center line while width used is the minimum dimension of the plotted areas with ends perpendicular to the center line. In this example, the width is 140 m and the length is 380 m.

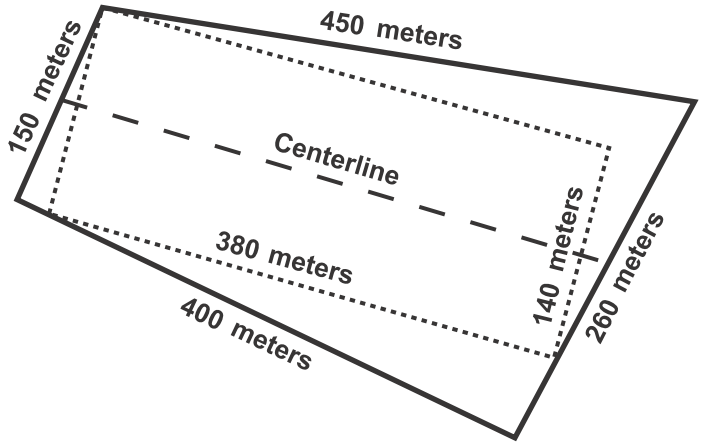

Figure C-2. Irregular-Shaped Drop Zone.

The imagery analyst computes flight time. For safety requirements, a DZ should be as large, or larger, than the commander's request. Normally, an area 460 m long and 180 m wide is the minimum requirement for the delivery of supplies. If a DZ of the desired length is not available, the flight time over the DZ (whatever its length) must be computed to determine how much of the load can be released in one pass and/or how many passes must be made to release the entire load. Always round the flight time down to the next lower whole second.

Flight time is computed using the following formula: T = L ÷ R = L ÷ (S x .51). The following legend applies:

- T = time over the DZ (in seconds).
- L = length of the DZ (in meters).
- R = aircraft ground speed (in meters per second).
- S = aircraft speed (in knots).
- .51 = conversion factor of knots to meters per second.

For example, an aircraft is flying at 105 kts (S) over a DZ measuring 150 m long (L).

$T = L \div R = L \div (S \times .51)$

$T = 150 \div (105 \times .51)$

$T = 150 \div 53.55$

$T = 150 \div 53$

$T = 2.83 = 2$

Slope Calculations

After the DZ area has been determined, the imagery analyst computes the slope. A map of the area is required for this task. The slope of a DZ should not be more than 30 percent, and should be round up to the nearest percent. Both vertical distance and horizontal distance must use the same unit of measurement (feet or meters). Use 3.281 as the conversion factor from meters to feet or .3048 to convert feet to meters. Use the following formula, which will be expressed as a percentage, to compute the terrain's slope: $SL = (VD \times 100) \div HD$. The following legend applies to the formula:

- SL = percent of slope.
- VD = vertical distance of the DZ (altitude difference between each end of the DZ length).
- HD = horizontal distance of the DZ.
- 100 = conversion factor for percent.

For example, the length of the DZ is 900 m, one end is at an altitude of 150 ft and the other end at 200 ft, the percent of slope is 1.7%, rounded up to 2%.

$SL = ([200-150] \times 100) \div (900 \times 3.281)$

$SL = (50 \times 100) \div 2{,}953$

$SL = 1.7 = 2\%$

The contour intervals on maps are in feet or meters. The bar scales are usually in meters, yards, statute miles or nautical miles. If the bar scale is used, a conversion from one unit of measure to another may have to be performed. If a Pl scale is used, the analyst must multiply the measurements by the map scale. To determine slope using a map, refer to the following steps and figures C-3 and C-4.

Step 1. Determine the elevation of each point. Neither point is on a contour line, so it will be necessary to interpolate. Point Y is located on an intermittent stream symbol, which may be confused with a contour line if care is not taken. The contour interval is 50 ft.

Figure C-3. Map Extraction (map not to scale).

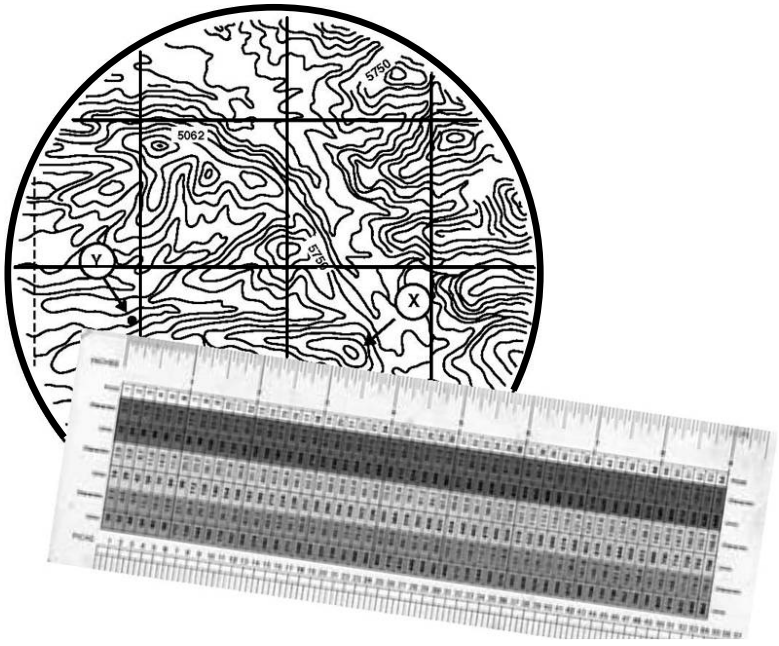

Figure C-4. Measuring from Dot to Dot (map not to scale).

Step 2. Measure the distance between points X and Y using a piece of paper, Pl scale, or boxwood scale. Make measurements from the center of one dot to the center of the other dot (see fig. C-4). A tube magnifier may be required to exactly align the scale with the centers of the two points to accurately determine the distance found. In figure C-4, the map distance (MD) is 2.95 cm. The ground distance is found by solving the following: GD = MD x DMRF.

GD = 2.95 cm x 50,000 = 147,500 cm = 1,475 m

When comparing elevations and horizontal distance, elevation is measured in feet and distance is measured in meters, so a conversion from one to the other is required.

GD = 1,475 m x 3.281 ft/m = 4,839.475 (rounded up to 4,840 ft)

Step 3. Use the slope formula: VD = change in elevation from point V to point Y:

SL = (VD ÷ HD) x 100 = (XY ÷ HD) x 100

For example, a DZ with a length of 4,840 ft (HD) has elevations of 5,925 ft and 5,475 ft.

SL = ([5,925 ft - 5,475 ft] ÷ 4,840 ft) x 100

SL = (450 ft ÷ 4,840 ft) x 100 = 9.2975; rounded up to 10%

SL = 10%

Surface and Obstacle Considerations

When both size and slope of a proposed DZ are acceptable, inspect imagery of the area for the presence of obstacles and potentially hazardous surface conditions. This requires the examination of photography in stereoscopic pairs as well as a review of available maps. Two major reasons for the examination of imagery are to protect troops from injury during a drop and to prevent the unsuccessful drop of equipment. The most acceptable DZ is a flat, resilient surface without obstructions.

Unfavorable or hazardous surface conditions are normally provided by the terrain detachment, including information on—

- Water.
- Marshland.
- Gullies.
- Drop-offs (cliffs).
- Dense trees.
- Dense low vegetation.
- Large rocks.
- Obstacles that are manmade features, such as—
  - Power lines and poles.
  - Buildings.
  - Towers.
  - Fences.
  - Military impediments (e.g., stakes, barriers, barbed wire).

Drop Zone Accessibility and Trafficability

A favorable DZ must have easy accessibility for both approach and exit. If possible, DZs near LOCs should be selected. Certain questions must be answered before DZ identification can occur and the tactical situation will add other questions, such as the following:

- Will the approach involve more troops and equipment or fewer troops and less equipment than the exit?
- Will the exit involve more troops and equipment or fewer troops and less equipment than the approach?
- Will the approach or exit occur during daylight or night?

When troops are parachuted into a DZ, it is important that they have an easy exit. The exit should be in the general direction supporting the ground tactical plan. When supplies or equipment comprise the load, personnel on the ground must be able to approach the area, recover the material, and exit with the material. When evaluating a potential DZ for accessibility, the type of load will be a major consideration. For example, if wheeled vehicles are parachuted into a DZ, troops on the ground may be able to approach the DZ through a densely wooded area or up a steep slope; however, the vehicles may not be able to exit through the forest or negotiate the slope.

A factor related to accessibility is the trafficability of the soil. Swampy soil or in some cases fine sand may rule out the selection of a DZ. The parachuted equipment may bog down or troops may not be able to approach or exit the area rapidly. Therefore, in order to afford easy cross-country movement of vehicles and personnel in and out of the DZ, trafficability of access routes must be considered.

Drop Zone Reports and Overlays

Normally, the imagery analyst assists all-source intelligence and GEOINT analysts with preparing a report in accordance with local SOPs. A primary DZ and alternate DZs that meet the specified intelligence requirements will be selected. This information is provided to the P&A cell OIC, who in turn recommends these to the ISC and G-2. Upon request, an overlay of the primary and alternate DZs will be prepared. Geospatial intelligence analysts generally will prepare this overlay.

IMAGERY INTELLIGENCE SUPPORT TO HELICOPTER LANDING ZONES STUDIES

An LZ may contain one or more landing sites. An HLZ is a ground area specified for landing assault helicopters to embark or disembark troops/cargo. Primary and alternate HLZs that meet the intelligence requirements will be identified, analyzed, and provided to the supported ground unit and aviation commanders. The ground unit commander (or helicopter unit commander) in coordination with the supporting air mission commander (AMC) will select the final location of the HLZ to best support the ground tactical plan.

General Helicopter Landing Zone Criteria

The same criteria used for determining a DZ apply when selecting an HLZ from maps, aerial photographs, and physical ground or aerial reconnaissance. However, additional information, normally supplied by the ACE commander or AMC, should also be used when selecting an HLZ. This should include the HLZ type and the number and type of helicopters used. An HLZ is a helicopter landing area that encompasses one or more helicopter landing sites, making a helicopter landing site a subdivision of an HLZ. The size of a landing site depends on the number of LPs and the size of the LPs. An LP is a designated touchdown point where a single helicopter may land.

The size of the landing site will depend on the number and size of LPs within it. As a guide, a helicopter requires a relatively level, cleared, circular area of 20 to 75 m in diameter. However, this may vary depending on the type of helicopter and because helicopters require more usable landing area at night than during the day. The criteria provided in figures C-5 and C-6 and C-7, on page C-10, represent guidance on LP preparation. Helicopter units will designate the size (small, medium, or large) to be used by their units for specific operations. Numerous considerations, such as helicopter type, unit proficiency, nature of loads, and weather conditions, may apply to the size of LPs used. General distances between LPs within a landing site in daytime landing are as follows (measured center to center):

- Small LPs: 80 ft (25 m).
- Medium LPs: 115 ft (35 m).
- Large LPs: 165 ft (50 m).

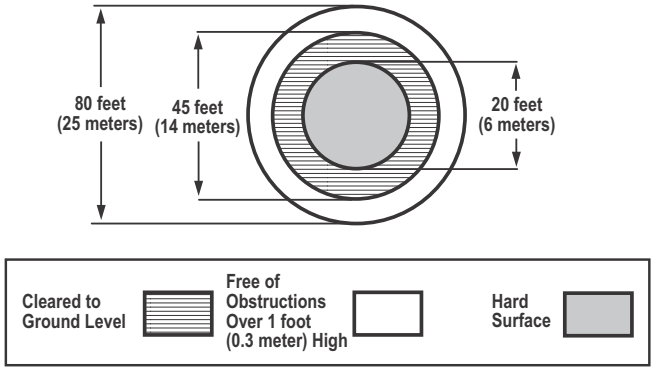

Figure C-5. Small Landing Point Dimensions.

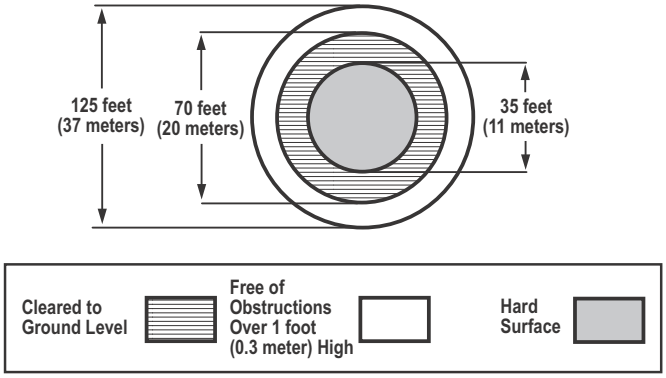

Figure C-6. Medium Landing Point Dimensions.

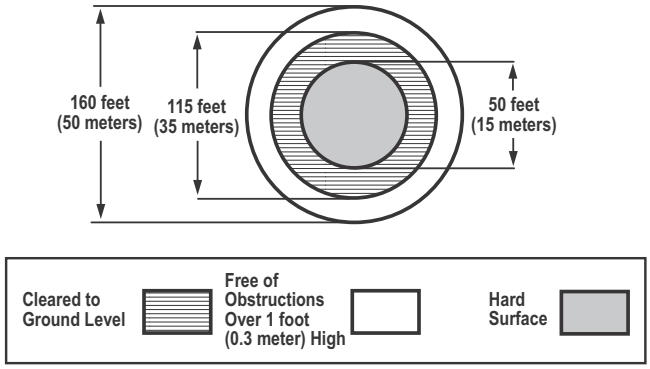

Figure C-7. Large Landing Point Dimensions.

Most helicopters cannot land or take off vertically when they are fully loaded; therefore, when they are, a larger area or a better approach is needed. The ACE commander has the final authority in establishing the landing area criteria for assigned helicopters in daytime and nighttime missions. This may change from time to time, depending on how heavily loaded the aircraft will be, the place and time of landing, and the anticipated weather conditions. During specific missions, the AMC may exercise this authority. For example, the area requirement may be larger when—

- A helicopter is heavily loaded.
- Helicopter cargo is sling loaded.
- A landing must be made at night or during other periods of reduced visibility.
- There are terrain obstructions or obstacles in the area.
- An area is located at high elevation.
- The temperature is hot or when humidity is high.

The ACE commander or AMC should provide the G-2 or ISC with the required dimensions for all HLZs, based on various flight and landing formations. This action will assist imagery analysts and all-source intelligence analysts with locating potential HLZs.

Helicopter Landing Zone Computations

When determining the size of the HLZ area, proceed in the same manner as for calculating the DZ area: first computing the required and then the potential HLZ areas. To determine the HLZ area, use the procedures explained in the following subparagraphs.

Step 1. Determine HLZ dimensions on photographs or maps. If the results are in fractions, round down to the nearest foot or meter. Use the same basis for all measurements (either feet or meters).

Potential HLZ length when measuring:	Potential HLZ width when measuring:
Imagery: GD = PD x DPRF	Imagery: GD = PD x DPRF
On a map: GD = MD x DMRF	On a map: GD = MD x DMRF

Step 2. Determine how many helicopters will be able to land in the potential HLZ area in a two-trail formation during daytime. Round up converted LP dimensions.

Step 3. Determine the number of LPs (or helicopters) from front to rear of the potential HLZ. Round down number of helicopters.

LPs from front to rear = potential HLZ length

Minimum recommended LP length

Step 4. Determine number of lateral LPs of the potential HLZ.

Number of lateral LPs = potential HLZ width

Minimum recommended LP width

Step 5. Determine the total number of helicopters LPs of the potential HLZ.

Total number of helicopter LPs = number of LPs from front to rear x number of lateral LPs

Slope Computations

The slope for an HLZ should not exceed 8 percent if the helicopter is to land. When the slope is more than 8 percent, provide the requester with the exact percent figure so he can assess alternatives and decide. Slope is important because when the ground slope is less than 8 percent, helicopters should land upslope. When the slope is more than 8 percent, helicopters should land side-slope (see fig. C-8 on page C-11). At the pilot's discretion, it may be possible for a helicopter to hover just in contact with the ground on slopes greater than 8 percent.

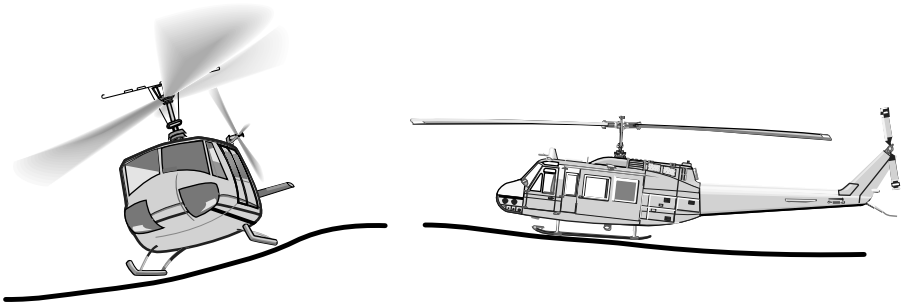
When the slope is greater than the allowable 8 percent, report this to the requester. The site may still be usable if the commander chooses to hover the aircraft and load/unload troops and supplies by rope or ladder.

When computing the slope, do not depend entirely on the map. Study imagery of the area as well. The map contour intervals may indicate that the percent of slope is sufficient, but sloping or rugged terrain can be seen only with a stereoscope.

To compute the slope of each potential HLZ, use the same formula that was used to find the slope for DZs: SL = (VD ÷ HD) x 100.

When computing the HLZ slope, consider the following:

- *Direction of positive slope*. The direction of positive slope is important for the approach and exit direction.
- *Number of aircraft used*. The AMC will provide the number of aircraft used.
- *The density altitude*. The altitude, temperature, and humidity determine the density altitude. For planning purposes, as density altitude increases, the landing area should increase proportionately.



Side Slope Up Slope

Figure C-8. Helicopter Landing on Side Slope and Up Slope.

- *Approach/departure directions*. When possible, the direction of approach and departure should be into the wind. However, if there is only one suitable approach direction due to obstacles or the tactical situation or in order to make maximum use of the available HLZ, most helicopters can land with a crosswind (10 kts or less) or a tailwind (5 kts or less). The same applies to departures from the HLZ.
- *Loads*. When fully loaded, most helicopters cannot ascend or descend vertically.

AIRCRAFT LANDING ZONE

An aircraft LZ (also referred to as runway or landing strip) is a specified location used for landing aircraft. Potential aircraft LZs are selected to meet the intelligence requirements of the supported ground and aviation units' commanders. Potential aircraft LZ locations will be identified and analyzed based on aerial imagery, current maps, and other available intelligence.

Aircraft Landing Zone Criteria

Aircraft LZs are established so aircraft can safely land and take off. They also provide guidance for aircraft while they taxi and park. They have one or more landing strips. The landing strip consists of a runway and may include taxiways, parking points, and dispersal areas. Selection of a potential aircraft LZ depends on the type of aircraft, runway dimension requirements (see Table C-1 on page C-13), surface, and location.

Unmanned aircraft systems sometimes require landing strips. The requirements for these vary. In order to ensure these requirements are met, close coordination with the aviation units that plan to use the landing zone is required for any aircraft landing zone products.

Table C-1. Runway Dimension Requirements.

	Airfield Type	Runway Length (in feet)	Runway Width (in feet)	Runway Shoulder (in feet)
Forward Area	Attack & Utility	N/A	N/A	N/A
	Vertical Lift	N/A	N/A	N/A
	Light Lift	1,200	60	10
	Medium Lift	2,500	80	10
Support Area	Attack & Utility	N/A	N/A	N/A
	Vertical Lift	N/A	N/A	N/A
	Light Lift	1,500	60	10
	Medium Lift	3,500	60	10
	Heavy Lift	6,000	100	10
	Tactical	5,000	60	4
Rear Area	Medium Lift	6,000	72	10
	Heavy Lift	10,000	156	10
	Tactical	8,000	108	20

Airfield Type

There are two types of aircraft LZs, classified according to their size and degree of improvement: a hasty landing strip and a deliberate landing strip. A hasty landing strip has an unimproved surface, which normally is acceptable for marginal weather, but is unusable during prolonged poor weather. After a period of occupation, most landing strips (terrain permitting) can be improved to meet the requirements of a hasty landing strip. A hasty landing strip has the following characteristics:

- Minimum length: 3,000 ft, plus a 10 percent overrun at each end.
- Minimum width: 50 ft, plus a 10-ft shoulder on each side.
- Minimum lateral clearance: 100 ft on each side of runway centerline.
- Has taxiways, parking areas, and may include dispersal areas.

A deliberate landing strip, at minimum, should have all the characteristics of a hasty landing strip plus any other facilities needed to meet the standards required by any aircraft. It has an all-weather capability and is usually a permanent installation with a control tower, hard surface runways, taxiways, and parking ramps.

Aircraft Landing Zone Computations

To determine the length and width of the area, use the same formula that was used to measure a DZ or an HLZ, and then identify the potential aircraft LZ by type. For example, if the photo scale is 1:20,000, the photo distance (length) is .08 ft and the photo distance (width) is .004 ft, then the potential aircraft LZ could be either a hasty or deliberate type depending on construction and facilities.

Slope Computations

When computing the slope, the maximum slope for a potential aircraft LZ should not exceed 10 percent. Always round slope up to the nearest percent. Use the same formula that was used to compute the SL of a DZ or HLZ:

$$\text{SL (expressed as a percentage)} = \frac{\text{VD}}{\text{HD}} \times 100$$

Surface and Obstacle Considerations

The surface of a potential aircraft LZ must be firm and smooth enough to allow heavily loaded aircraft to land, taxi, park, and take off without delay or damage to the aircraft. It should be located away from obstacles, such as mountains, telephone wires, tall buildings, and trees. The area should be free of heavy rocks and stumps so troops can clear it easily. This is particularly important for hasty strips, which may have to be established quickly. The area should be dry, as water or marshland can cause early erosion.

Landing Zone Accessibility

An aircraft LZ should have convenient access, such as roadways or other level terrain, to and from the area. If there are prevailing winds, the runway should be oriented, if possible, so that aircraft can land and take off into the wind. The minimum size of an aircraft LZ depends on the type of loads, the direction and velocity of winds, and the condition of the ground. Consider the following factors when establishing an aircraft LZ:

- Soft, wet, slippery, or any other unfavorable surface conditions will increase the need for a longer aircraft LZ.
- Crosswinds may require an increase in width of the aircraft LZ.
- Uphill take off and downhill landings will require longer runways. The maximum slope on any aircraft LZ should not exceed 10 percent.
- Obstacle clearance is measured from the obstacle to the approach and departure end (if there are obstacles at the approach and departure ends of the aircraft LZ). Be sure to obtain a 10:1 clearance ratio (same as used for an HLZ).

Aircraft Landing Zones Overlays

Per the intelligence production requirement, all-source intelligence analysts, assisted by imagery analysts and GEOINT analysts, will prepare an overlay of the potential primary aircraft LZ and an alternate aircraft LZ, if deemed necessary. A relief and drainage overlay may also be provided. Aircraft LZs are normally referred to by their nickname or a color. Situation and time permitting, GEOINT analysts will prepare this overlay.

IMAGERY INTELLIGENCE SUPPORT TO BEACHES STUDIES

Imagery intelligence support is crucial for amphibious operations. Imagery intelligence helps to provide commanders with the information they need to decide which beaches to use and how those beaches can be used for amphibious operations. They do this through detailed analysis of the beaches and surrounding areas.

Beach Definitions

A beach is the area extending from the shoreline inland to a marked change in physiographic form or material, or to the line of permanent vegetation. In amphibious operations, a beach is that portion of the shoreline designated for landing of a tactical organization. A landing beach is that portion of a shoreline usually required for the landing of a battalion landing team. However, it may also be that portion of a shoreline constituting a tactical locality (such as the shore of a bay) over which a force larger or smaller than a battalion landing team may be landed. A beach landing site (BLS) is a geographic location selected for across-the-beach infiltration, exfiltration, or resupply operations. A beachhead is a designated area on a hostile or potentially hostile shore that, when seized and held, ensures the continuous landing of troops and materiel and provides maneuver space requisite for subsequent projected operations ashore. Finally, a landing area is the part of the operational area within which are conducted the landing operations of an amphibious force. It includes the beach, the approaches to the beach, the transport areas, the fire support areas, the airspace above it, and the land included in the advance inland to the initial objective.

Beach Landing Site Factors

A BLS is a continuous segment of coastline over which troops, equipment, and supplies can be landed by surface means. Primary and alternate BLSs are selected and prioritized after considering the commander's intent and guidance, CONOPS and scheme of maneuver, enemy disposition, size of the area required, terrain features, weather factors, supporting fire, and proximity of the objectives.

Amphibious operations require a detailed study of hydrography, weather, climate, and terrain. The terrain portion is primarily the responsibility of MAGTF GEOINT analysts. A tactical study of the terrain is prepared by all-source intelligence analysts with major assistance from imagery analysts and GEOINT analysts. (See MCWP 2-3 and MCWP 2-26, *Geographic Intelligence*, for additional information on tactical studies of the terrain.)

The landing force commander selects specific landing beaches from available beach landing sites. When the amphibious task force is composed of two or more attack groups with related landing groups, a landing area may be selected for each attack group. In this case, each landing group commander selects the landing beaches from within the assigned area. The principal factors in the selection of landing beaches are—

- Suitability for beaching landing ships, landing craft, and amphibious vehicles.
- Beach trafficability.
- Suitability of offshore approaches.
- Number, location, and suitability of beach support areas and beach exits.
- Location, type, and density of beach obstacles, including underwater obstacles.
- Nature of the terrain immediately inland from the beaches.
- Suitability of LOCs—including roads, railroads, and waterways.
- Suitability of the beach from the standpoint of expected weather and tidal conditions.
- Known hostile force dispositions, strengths, and capabilities.

Beaches are categorized by their shape (see fig. C-9):

- Concave (point A to point B).
- Convex (point B to point C).
- Straight (point C to point D).
- Irregular (point A to point D).

Beach Types

Beach types include the following:

- Coastal plain.
- Coastal ridge.
- Cliff or terrace.
- Coral reef.
- Glacial.
- River mouth or delta.
- Pocket.

Coastal Plain. A landing on a wide coastal plain beach provides unrestricted maneuver room, so a subsequent advance from the beach can be made in any direction. Boundaries and objectives are more difficult to locate on this type of terrain; there are few prominent registration points for artillery, naval gunfire, and aerial bombardment. Usually there is no natural defensive terrain on the flanks of the beachhead, so more troops are required to protect the flanks. Some coastal plain beaches are near marshy and swampy terrain, which may hinder movement from the beach.

Coastal Ridge. A coastal ridge beach has terrain that rises evenly to a considerable distance back from the beach that gives the defender excellent observation and fields of fire. More commonly, the coastal area remains flat for some distance and then rises in a steep gradient to a coastal ridge.

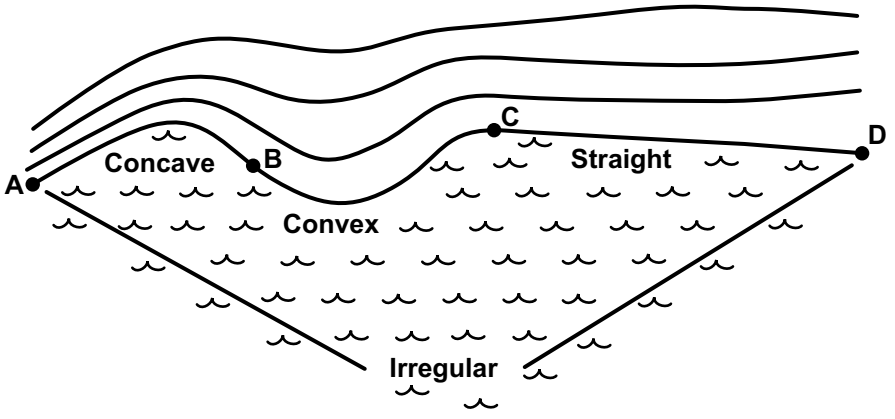


Figure C-9. Beach Categories.

Cliff or Terrace. A cliff or terrace beach is usually quite narrow. The delineation of a cliff beach from a terrace beach basically is established by the height of the landmass immediately behind the beach. Cliff beaches may have rocks and debris that accumulate by erosion of the adjoining severe terrain. The surface is made up of the same type of material as the major adjacent landform. If wave action is strong on a cliff beach, any fine material is washed away resulting in a beach covered with boulders or barren rock. Cliff beaches isolated from strong wave action are usually composed of sand and are similar in surface materials to coastal plain beaches. A terrace beach may be composed of loose sand or rocks; it may be barren rock or strewn with boulders.

Coral Reef. A coral reef beach is located in the coral region (normally between 30 degrees north latitude and 30 degrees south latitude) protected by a barrier reef with fringing reef along the shoreline, or it is located on an atoll. Any beach protected by a barrier reef is composed primarily of fine coral sand (coral skeletal remains, broken shells, and hardened algae) and is usually firm and narrow. When the beach or fringing reef is exposed to wave action, the foreshore is eroded. The coral reefs themselves normally present significant obstacles with abrupt seaward slope and the exposed offshore edge of the reef is steep. The upper surface of the reef may be extremely rough with jagged coral formations rising above the surface and deep pits indenting the surface of the reef. An atoll is a ring-shaped coral island or group of coral islands enclosing a lagoon or another island. It has the same basic characteristics as the coral barrier reef.

Glacial. Glacial beaches are usually found in the higher latitudes, normally above 60 degrees north and 60 degrees south latitude. These beaches were eroded by glacial action and have round and irregular shorelines with numerous inlets; some may be quite deep, long, and narrow, with almost perpendicular, smooth mountain walls rising to great heights. This type of coast is very dangerous to navigation because of the islands and rocks off entrances to the inlets. The beach may be composed of material that has no geologic relationship to the coastline with depositions of material carried from the hinterland by the glaciers. This is often a mixture of silt, sand, gravel, and rocks.

River Mouth or Delta. This type beach is easy to identify due to its proximity to the mouth of a major stream or river. It undergoes a greater physical change than the other beach types, and the foreshore is composed primarily of the type of sediment carried by the stream or river.

Pocket. A pocket beach is found on many of the coasts throughout the world and has a wide range of composition and topography. The irregular coastlines, where pocket beaches are quite common, are made up of headlands and indentations with the pocket beaches found in the indentations. This type of beach is divided into two general areas: the end zones and central zone.

The end zones are those areas on the flanks inside the beach termination points. They are protected from direct wave action by the headlands and subsequently the beach soil is usually fine sand.

The central zone is that portion of the entire beach between the end zones. It exhibits the same characteristics and soil conditions of any beach exposed to wave action. Any highlands behind the beach may provide the source material continually washed down and deposited on the beach. Lowlands behind the beach, however, will have little effect on its character.

A common problem affecting some pocket beaches is that many of the bays or other indentations fronting the beach may become blocked by sandbars built up by sand drifting along the coast in long shore currents. These sandbars may become attached to the mainland at the upstream end, and any open channel that might exist will occur at the downstream end. Sometimes these sandbars connect offshore islands to the mainland. Pocket beaches are usually concave shaped.

Beach Landing Site Criteria

The required beach area for amphibious operations is calculated based on the original requester's guidance, the type of forces conducting the ship-to-shore maneuver, local SOPs, and METT-T. To identify whether an area is suitable for beach landings, intelligence analysts will require the following information:

- Minimum length of beachfront necessary.
- Types of equipment being landed.
- Types of transports to be used, including length and width of each transport type.
- Transport capability. (Can it land on the beach? What is the required minimum depth [draft]?)

Beach Landing Site Computations

As with the calculation of measurements of DZs, HLZs, and aircraft LZs, beach landing length is computed using the formula GD = PD x DPRF. Measurements are taken from one termination point to another (see fig. C-10) and rounded down to the nearest meter.

The beach termination points are the extreme ends of the selected beach. The total length of the beach is measured between these points following the natural coastline.

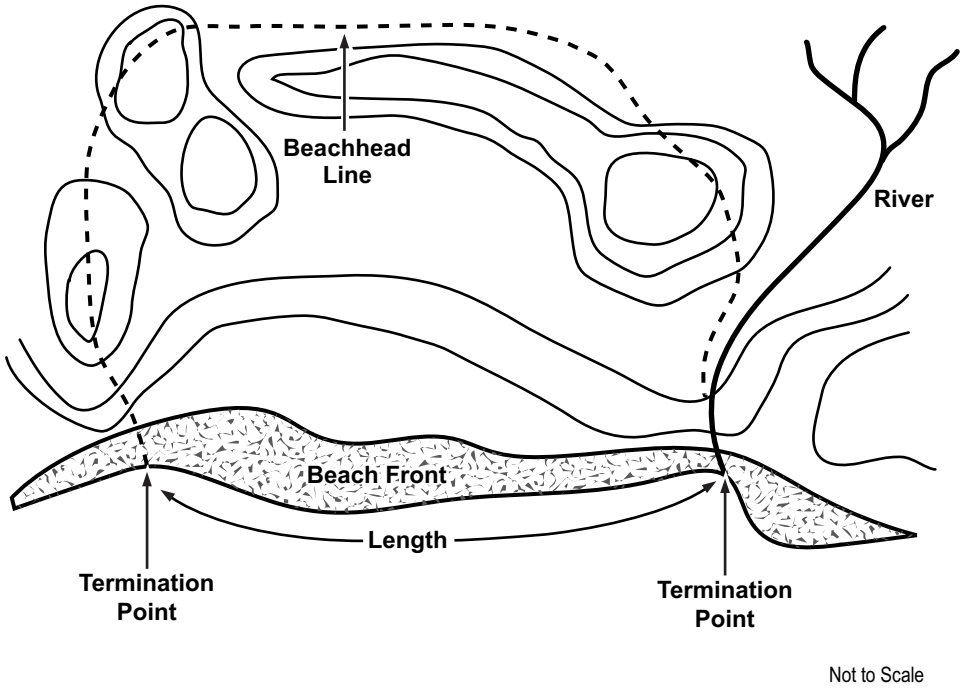

Figure C-10. Landing Beach Length.

The beach width is calculated using the horizontal dimensions of the beach measured at right angles to the shoreline from the line of extreme low water inland to the landward limit of the beach (the coastline). It usually will not be uniform and, therefore, is determined at various points along the beach.

The beachhead line is roughly semicircular and encompasses the area near the coast large enough for the deployment of the assault force and its supplies and equipment, and usually includes terrain features that are the initial objectives of the assault force. The beachhead line, if established, must be held so the subsequent landing forces can land and deploy in proper battle order. Loss of the beachhead—or major enemy force penetration into it—places the entire amphibious operation in jeopardy.

The beachfront extends from low tide limit to the high tide limit and usually coincides with the foreshore (see fig. C-11).

Percent of Slope and Gradient Computations

Measurements of the width of the beachfront are taken to calculate a beach landing length. Apply the same formula that was used to determine the percent of slope of a DZ, HLZ, or aircraft LZ:

SL = (VD ÷ HD) x 100

The VD is the height difference of the beachfront, which is from the edge of the beachfront (low tide limit) to the high tide limit. The HD is the horizontal (ground) distance of the beachfront. Always round up the percent of slope to the nearest percent.

Combined offshore or foreshore/back shore beach gradient is expressed as a ratio of the rise in elevation of one unit of measure to the horizontal (ground) distance in a number of the same unit of measure (e.g., 1:15).

Gradient = VD ÷ HD

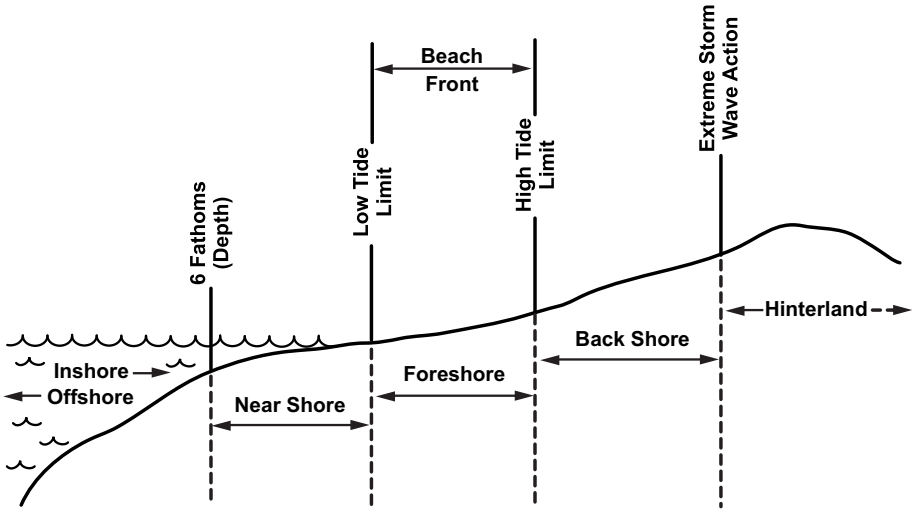

Figure C-11. Shores.

A quick way to obtain the gradient (1:) is to invert the fraction and divide the denominator by the numerator. Round up fractions to the next whole number (e.g., 1:50.52 = 1:51). For example, if VD equals 150 m and HD equals 3,000 m, then the gradient is—

Gradient = 1: (3,000 ÷ 150) = 1:20

When computing the combined foreshore/back shore gradient, measure from the shoreline to the nearest 20-m contour line used for the start of the hinterland. Be sure to transfer the 20-m contour line from the map to the photograph by interpolation prior to making the measurement. The gradient is further expressed as shown in table C-2.

Table C-2. Beach Gradients.

Less than 1:120	Flat
1:120 to 1:60	Mild
1:59 to 1:30	Gentle
1:29 to 1:15	Moderate
1:14 or more	Steep

The depth lines or curves illustrated at 1, 2, and 3 fathoms (1 fathom = 6 ft) (see fig. C-12) are established to determine the offshore gradient and to assist in the safe approach of the landing craft. The depth curves may be a series of dots (as shown) or solid lines.

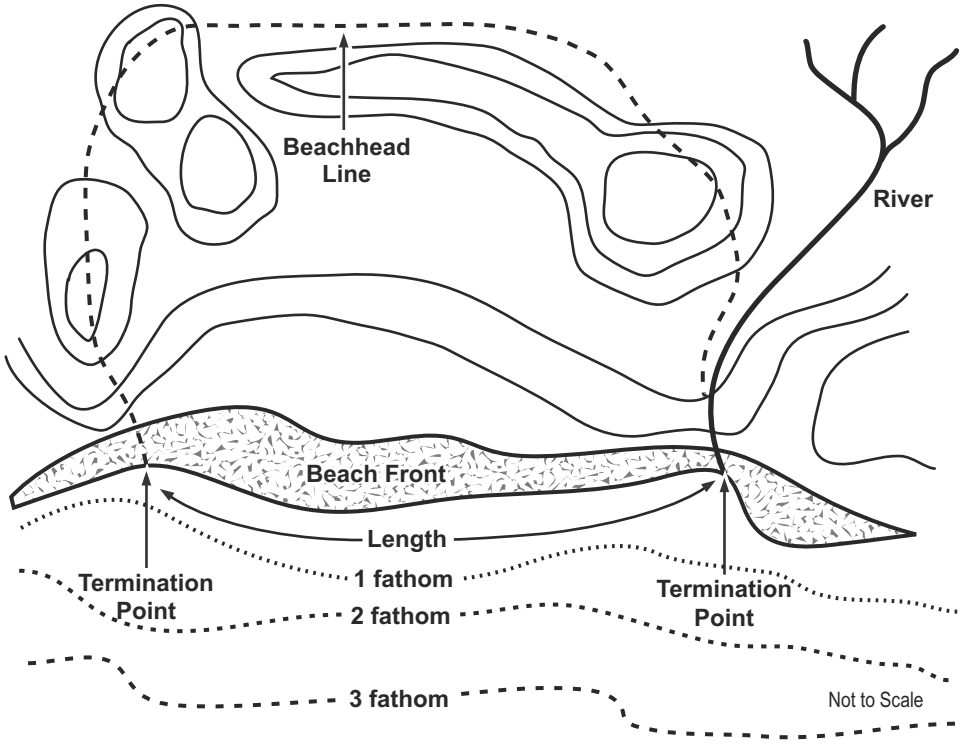

Figure C-12. Typical Beach Landing Area.

Surface and Obstacle Considerations

Normally, the surface condition of the combined foreshore and back shore areas is considered critical upon landing. The foreshore is generally white; the back shore begins where the beach discoloration changes from white to brownish gray and ends at the beginning of the hinterland by revealing a darker tone and taller vegetation on aerial photography. Unfavorable or hazardous surface conditions include the following:

- Large rocks or reefs.
- Drop-offs (cliffs).
- Dense trees.
- Dense vegetation.

Obstacles include the following:

- Buildings.
- Military impediments (e.g., landing craft barriers, barbed wire).

Beach Landing Site Accessibility

Because of the configuration of shorelines, usually the area most suitable for the execution of a landing operation is also the most easily organized for defense. The ideal beach for amphibious landing is one with—

- No obstructions in the sea approaches.
- Deep-water close inshore.
- Near shore gradients that are sufficiently deep for dry ramp beaching of landing craft and ships.
- Soil composed of firm sand with gentle gradients or slopes.
- Small tides.
- No currents.
- No surfs.

The beach terrain should be—

- Gently rising, relatively clear, and have a firm surface that has adequate drainage.
- Flat or gently rising terrain, backed by a coastal range high enough to mask the landing area.

Ideal conditions are rarely found, so suitable areas must be evaluated to determine those that come nearest to optimum requirements. Other terrain considerations include dunes, mountains, and sandbars.

Dunes. Ground that is sharply broken by extensive dunes or a low coastal plateau provides the attacker with concealment from the defender's observation. However, small compartments and corridors limit the range of defensive fire. Dunes are classified as transverse, longitudinal, and coastal.

Transverse dunes are mounds of sand with their longest dimensions oriented at right angles to the prevailing wind. They usually have a steeper slope on the leeward side than they have on the windward side.

Longitudinal dunes are sand formations with their longest dimensions oriented in the same direction as the prevailing wind. They may have a symmetrical shape or may be without any particular shape at all and may be over 100 miles long. They are usually not backed by areas of standing water, such as swamps or marshes.

Coastal dunes, because they are formed by windblown sand, are quite unstable landforms. They may appear in one location as a transverse dune, only to disappear and reform as a longitudinal dune elsewhere. The winds responsible for their formation may also be the means of their destruction.

Mountains. Mountains located directly on the sea usually limit the number of beaches large enough to accommodate a landing force of effective size. Where steep ground is lightly defended or neglected by the defender, a small force may seize it and gain surprise. Airborne or airmobile troops may be used to block the movement of defensive reserves to the landing area or to secure passes through the mountains. Such action prevents the defender from interfering with the amphibious landing.

Sandbars. These offshore sand formations are usually found near coastlines with gentle beach gradients. During stormy weather the sandbars will be found further offshore than during calmer weather conditions. Sandbars paralleling the coast may cause a lagoon to form between themselves and the coastline; direct access to the shore is dependent on openings (channels) through the sandbar areas. The locations of these channels are highly variable, and current photography is required before the actual landing takes place. Soil analysis, beach materials, and other trafficability aspects are normally reported by terrain and soil analysts; however, imagery analysts will determine beach exits, such as roads or airstrips.

Beach Landing Site Collection Checklist Preparation

A collection checklist must be prepared for each potential BLS using the following items:

- Identification: local name and military designation.
- Location:
  - Map reference, including the series and sheet number(s) of both tactical and air/ground series.
  - Political unit, area, universal transverse mercator (UTM) coordinates, and geographic coordinates of the termination points.
  - Landmark reference, a description and location of the landmark and azimuth and distance from landmark to termination point.
- Related water body or watercourses (cross-reference to appropriate collection file).
- Length between termination points.
- Seashore form (concave, convex, straight, or irregular).

- Coastal terrain type, such as emergent, submergent, compound, coral reef, delta, volcanic, fault, or manmade.
- Alignment (high-water shoreline and low-water shoreline).
- Beach width at low water.
- Beach width at high water.
- Backshore:
  - Slope.
  - Material (composition, texture, trafficability).
  - Obstacles.
  - Vegetation.
- Foreshore:
  - Slope.
  - Material (composition, texture, and trafficability).
  - Obstacles.
  - Vegetation.
- Near shore (give alignment and distance from low water shoreline):
  - 10 m (5 fathoms) depth line at low water.
  - 6 m (3 fathoms) depth line at low water.
  - 4 m (2 fathoms) depth line at low water.
  - 2 m (1 fathom) depth line at low water.
  - Obstacles.
- Reefs (near shore):
  - Type and location.
  - Distance from low water shoreline.
  - Length and width.
  - Slope (direction).
  - Depth to surface of reef at low tide.
  - Depth to surface of reef at high tide.
  - Height of surface above water at high and low tide.
  - Effects of surf.
  - Effects on tide.
  - Channel through reef (alignment, width, and depth at low water).
- Reefs (offshore):
  - Type and location.
  - Distance from low water shoreline.
  - Length and width.
  - Slope (direction).
  - Depth to surface of reef at low tide.
  - Depth to surface of reef at high tide.

  - Height of surface above water at high and low tide.
  - Effects of surf.
  - Effects on tide.
  - Channel through reef (alignment, width, and depth at low water).
- Offshore conditions:
  - Water depth.
  - Offshore islands (location and characteristics).
  - Sandbars:
    * Location and distance from low water shoreline.
    * Length and width.
    * Consistency.
    * Slope (seaward and landward).
    * Passages (alignment, width, and depth).
    * Depth at high and low waters.
    * Obstacles (type, location, and characteristics).
- Beach features (natural and manmade, such as cusps, runners, stream mouths, groins, piers, or outfall pipes):
  - Type and location.
  - Number and extent.
  - Bypass possibilities.
  - Influence on operations.
- Tide:
  - Type (diurnal, semi-diurnal, or mixed).
  - Type range (spring, topic, and diurnal).
  - Range.
  - Meteorological effects.
- Surf:
  - Breakers (type, average height, distance formed from shorelines).
  - Period.
  - Width of surf zone.
  - Direction from which swells approach coast.
  - Weather and seasonal effects.
- Currents:
  - Location.
  - Direction.
  - Velocity.
- Beach exits:
  - Type and location.
  - Number and condition.
- Coastal terrain (cross-reference to appropriate collection file):

  - Critical terrain features (location, type, bypasses, and influence on operations).
  - Obstacles (location, type, extent, bypasses, and influence on operations).
  - Cross-country movement (troops, wheeled vehicles, and tracked vehicles).
- Support area concealment and cover (location and type).
- Dispersal and storage area (location and description).
- Availability of fresh water (location and quantity).
- Defenses (location and type).

Terrain overlays are normally prepared by the terrain analysis detachment and added to the checklist. Overlays include presentations depicting cross-country movement, vegetation, slope, soil drainage pattern, and ridgelines.

Beach Landing Site Overlays

Imagery analysts assist all-source intelligence and GEOINT analysts with preparing overlays of the proposed primary and alternate beach landing sites. Beach landing sites are referred to by their nicknames. See MCWP 2-26 for information on the preparation of overlays.

APPENDIX D
NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

BACKGROUND

Imagery analysts use the NIIRS to define and measure the quality of images and performance of imaging systems. Through a process called rating an image, imagery analysts use the NIIRS to assign a number indicating the interpretability of a given image. The NIIRS concept provides a means to directly relate the quality of an image to the interpretation tasks for its use. Although the NIIRS has been applied primarily in the evaluation of aerial imagery, it also provides a systematic approach to measuring the quality of photographic or digital imagery, the performance of image capture devices, and the effects of image processing algorithms.

The NIIRS is a task-based scale consisting of nine graduated levels. At each level, representative exploitation tasks (termed criteria) indicate the level of information extracted with an image of a given interpretability level. For example, in an NIIRS 2 image, imagery analysts should be able to detect large hangars at an airfield; whereas, in an NIIRS 8 image, they should be able to identify the rivet lines on bomber aircraft. Even more detailed information can be obtained from an image at a higher NIIRS level.

The NIIRS was designed to refer to a wide range of image quality. An NIIRS level of 0 is defined as having no value for intelligence purposes; however, the definition of level 0 is open to debate. While, the upper end of the scale is defined by the best available imagery of a given type, it is not necessarily indicative of any specific operational system.

The NIIRS measures the information potential (i.e., interpretability of an image). This means that specific objects listed in the criteria, such as aircraft, need not be present, but the physical attributes of the image would have the specified information value if the specific object from the criteria were present.

The NIIRS relies on the experience of imagery analysts to be able to extrapolate or imagine how well criteria would be rendered if those features were present in the image to be rated. Because each rating refers to specific tasks the imagery analyst can or should be able to do, it has a more precise meaning than, for example, when such subjective words as *good* or *fair* are used. Thus, because imagery analysts can use the same yardstick to measure interpretability, judgments become more uniform.

The NIIRS takes into account the important factors that affect image interpretability. For example, image resolution, measured as ground resolved distance or ground sample distance, has a significant effect on interpretability; moreover, spatial resolution alone does not determine the NIIRS of an image, since sharpness, noise, and contrast also influence the NIIRS. These effects may be due to system parameters (e.g., optical quality, focal plane characteristics), acquisition conditions (e.g., sun angle, atmospheric haze), and exploitation conditions (e.g., duplicate film quality, softcopy monitor quality). By design, the NIIRS is independent of a particular imaging system. See table D-1 for a listing of NIIRS ratings and ranges.

Table D-1. National Imagery Interpretability Rating Scale Rangers.

NIRS Rating	Range in Meters
0	N/A
1	Over 9.0
2	4.5–9.0
3	2.5–4.5
4	1.2–2.5
5	0.75–1.2
6	0.4–0.75
7	0.2–0.4
8	0.1–0.2
9	Less than 0.1

PRINCIPAL USES OF THE NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

There are several primary uses for the NIIRS, including—

- Communicating imagery interpretability. (Can this image answer the intelligence requirement, both now and when archived?)
- Developing collection requirements. (Can an imagery system collect the required information? Can the currently available imagery missions collect the information?)
- Assessing mission collection satisfaction. (Does the image satisfy the intelligence requirement?)
- Assessing technical performance. (Is the imagery system working as planned?)

PROCEDURE FOR ASSIGNING THE NATIONAL IMAGERY INTERPRETABILITY RATING SCALE RATING LEVELS CRITERIA

The NIIRS criteria are expressed in terms of how one is able to *detect*, *identify*, or *distinguish between* objects, features, or activities. *Detect* is the capability to find or discover the presence or existence of an installation, object, activity, or item of intelligence interest based on its general

shape (configuration) and on other contextual information in the scene. Some level of identification is implied in detection, so that the relatively gross feature or item detected can be properly named or classified. *Identify* is the capability to name an object by type or class based primarily on its configuration and detailed components. As used in NIIRS, identification is based on the observation of actual physical detail and not through information from other sources. *Distinguish between* is the capability to determine that two detected objects are of different types or classes based on one or more distinguishing features.

The following guidelines allow NIIRS to be used to communicate image interpretability, evaluate mission performance, and plan for new imagery systems:

- When assigning an NIIRS level, the imagery analyst should evaluate a target within an imagery segment or the entire area on the segment, as necessary, to meet the imagery analyst's task. The imagery analyst will assign an NIIRS level that best characterizes the overall interpretability of the target or area.
- The imagery analyst should neither ignore nor emphasize exceptionally good or poor portions of the image segment.
- When considering clouds, shadows or other localized degradations, the imagery analyst should rate the target or area with NIIRS level 0 only when the degradation precludes using it for interpretation. If the AOI is degraded but interpretable, the imagery analyst should assign an NIIRS that best represents its interpretability.
- The imagery analyst should ignore shadows cast by individual items of intelligence interest.

PANCHROMATIC NATIONAL IMAGERY INTERPRETABILITY RATING SCALE, OCTOBER 2008

Air Order of Battle

Rating Level 0: not applicable.

Rating Level 1: not applicable.

Rating Level 2:

- Distinguish between taxiways and runways at medium to large airfields.
- Identify individual revetments/hardened aircraft bunkers.
- Detect the presence of large airfields by the configuration of the facility (e.g., petroleum, oils, and lubricants [POL] storage, major support facilities, and runways).

Rating Level 3:

- Identify the wing configuration (e.g., straight, swept, delta) of all large aircraft (e.g., 707, 747, BEAR, BLACK JACK).
- Detect the presence of small fighter aircraft.

- Detect weapons storage areas by their physical security and configuration (e.g., 5 or more buildings/bunkers).
- Identify a control tower at an airfield.
- Detect radar sites (e.g., ground control intercept, ground controlled approach, and instrument landing system) at an airfield.

Rating Level 4: identify a BADGER, BACKFIRE, or CANBERRA by overall configuration.

Rating Level 5:

- Identify the propellers on transport aircraft (e.g., RS-COOT, COKE, CURL; CA-DASH 7, BUFFALO; INT-F27).
- Detect canvas covering on small fighter aircraft.
- Identify small fighter aircraft by type (e.g., RS-FLOGGER, FISHBED; US F-16; INT-TORNADO, JAGUAR; FR-SUPER ENTENDARD, MIRAGE).
- Identify medium helicopters (e.g., RS-HIP, HIND; US-Blackhawk; FR-SUPER FRELON, PUMA).

Rating Level 6:

- Identify dummy fighter aircraft by observation of discrepancies in wing sweep, root chord, or other features.
- Detect the presence of missiles loaded onto medium or large fighter aircraft.
- Distinguish between FITTER-A and other FITTER models by the number of wing fences.
- Identify individual approach lights at the end of a runway.

Rating Level 7:

- Detect canard on missiles carried on fighter aircraft.
- Distinguish between fairings, bulges, and antennas on fighter-sized aircraft.
- Identify the individual steps on a mobile passenger stairway.
- Detect canopy seam on small fighter aircraft (e.g., RS-FLOGGER, FISHBED; US F-16; INT-TORNADO, JAGUAR; FR-SUPER ENTENDARD, MIRAGE).
- Identify all structural lines, including butt joints, lap joints, rivet lines, and weld seams on large commercial or military transports (e.g., 747, Condor, C-5, AIRBUS 340).

Rating Level 8:

- Identify separate rungs on cockpit ladders.
- Detect elements internal to the cockpit (e.g., seat, other cockpit components).

Rating Level 9: not applicable.

Cultural Order of Battle

Rating Level 0: interpretability of the imagery is precluded by obscuration, degradation, or very poor resolution.

Rating Level 1: identify a small cluster of houses in a rural area by overall pattern.

Rating Level 2: detect individual two or three story buildings.

Rating Level 3:

- Detect trains or strings of standard rolling stock on railroad tracks (not individual cars).
- Detect large vehicles (e.g., trucks/buses) on highways.
- Detect rows of vehicles parked in a parking area.

Rating Level 4:

- Distinguish between rail tank cars, box cars, and gondola cars.
- Distinguish between large trucks and buses.

Rating Level 5:

- Identify the front windshield on a light-colored automobile.
- Identify trucks as cab-over-engine or engine-in-front.
- Detect (but not necessarily distinguish) cattle, camels, horses, and similar sized animals in open areas.

Rating Level 6:

- Detect a sunroof on a light-colored automobile.
- Detect people on sidewalks or market areas (including the shadows cast by people).
- Detect individual oil drums/55-gallon barrels.

Rating Level 7:

- Determine the presence of a luggage rack on the roof of a light colored vehicle.
- Determine the direction a railroad switch is set based upon rail position.

Rating Level 8:

- Identify the arms and legs on an individual.
- Distinguish between a person on a motorcycle and a person on a motor scooter.
- Identify the ribbing in the bed of a pick-up truck.

Rating Level 9:

- Distinguish hands/feet from limbs.
- Distinguish between types of military small arms being carried by an individual (e.g., rifle or rocket propelled grenade [RPG]).
- Identify farm or construction tools by general shape (e.g., shovel, pitchfork, pick, ax, sledge hammer).

Electronic Order of Battle

Rating Level 0: not applicable.

Rating Level 1: not applicable.

Rating Level 2: not applicable.

Rating Level 3: identify radar/guidance areas of a SAM site, based on configuration.

Rating Level 4: identify the presence of a SATCOM site (Orbit A) by the presence of large SATCOM dishes (10 m or greater in size).

Rating Level 5:

- Detect civilian SATCOM dish (approx 1.62 m) on a rooftop.
- Detect a building-mounted VHF communication antenna.
- Identify the individual posts in a rhombic or quadrant array.
- Distinguish between TALL KING A, B, C, and D radars.

Rating Level 6:

- Distinguish between an ODD PAIR and an ODD GROUP by the antenna placement on the van.
- Detect the leveling/transport equipment on a TIN SHIELD radar.
- Identify the leveling/transport equipment on a BARLOCK or BACKTRAP radar.
- Distinguish between a SPOON REST C/D by the number of elements.

Rating Level 7:

- Identify the DATA LINK ANTENNA on BILL BOARD EW radar.
- Identify the feed structure of the target acquisition radar on the 2S6 when deployed.
- Distinguish between the individual FEED HORNS on a SQUARE PAIR radar.
- Identify whip antennas on box body vans and trailers.
- Detect individual elements of a Yagi array on a mobile electronics van.

Rating Level 8:

- Identify feed horn on small dish antenna (1.7 m or smaller in size).
- Identify framework on rear sides of CLAM SHELL parabolic dish.

Rating Level 9: not applicable.

Ground Order of Battle

Rating Level 0: not applicable.

Rating Level 1: not applicable.

Rating Level 2: not applicable.

Rating Level 3: identify the areas of a ground forces installation (e.g., living areas, athletic fields, motor pools, parade grounds, obstacle course).

Rating Level 4:
- Identify riveted bunkers at a ground forces facility.
- Identify an AAA gun site.
- Detect a small convoy of civilian vehicles (cars, pick-ups, sport utility vehicles).

Rating Level 5:
- Identify tracked vehicles by general type, when in groups.
- Detect the gun tube on large field artillery guns.

Rating Level 6: identify the shape of a tank turret as round, elliptical, or angular.

Rating Level 7:
- Identify gun barrels on 2S6.
- Distinguish between tracks made by wheeled and tracked vehicles.
- Identify a ZSU-23/4 self-propelled antiaircraft gun by the GUN DISH radar.

Rating Level 8:
- Detect a stack of military small arms (e.g., rifles, shoulder-fired weapons).
- Identify type of muzzle brake on towed field guns as multiple baffles.
- Identify individual grates in engine vents on tanks and armored personnel carriers.
- Identify the muzzle brake perforations on a D-30 howitzer.
- Detect a person carrying military small arms (e.g., rifle, RPG).

Rating Level 9:
- Identify the type of clothing (e.g., civilian attire or military uniform) on an individual.
- Identify shoulder-fired weapons (e.g., RPG/SA-7/14, REDEYE, STINGER).
- Detect whether an individual is wearing external body armor.
- Read tactical vehicle markings.
- Distinguish between types of military small arms (e.g., rifle or RPG) being carried by an individual.

Missile Order of Battle

Rating Level 1: not applicable.

Rating Level 2: not applicable.

Rating Level 3:
- Detect a mobile intercontinental ballistic missile (ICBM) or an intermediate-range ballistic missile base by patterns of buildings and roads.

- Detect a SAM support facility for SA-2/CSA-1 missiles on the basis of its configuration.
- Identify a major missile test range (e.g., Tyuratam) by the presence of roads with wide radius curves, railroad loading docks, and the presence of heavy equipment, such as missile gantries.
- Detect a launch complex at a known missile test range.
- Identify a SA-10 A/B launch site based on site configuration.
- Identify radar and guidance areas at a SAM site by the site configuration, mounds, and presence of numerous concrete aprons.

Rating Level 4:

- Distinguish between an occupied and an unoccupied fixed SAM site.
- Detect a security fence erected around a missile launch site or transporter.
- Detect a field deployed SAM unit on the basis of equipment types present (e.g., launcher, missile, transloader).
- Detect individual single-bay garages at SS-25/27 bases.

Rating Level 5:

- Detect an erected missile on a short-range ballistic missile (SRBM)/medium-range ballistic missile transporter-erector-launcher (TEL) missile platform.
- Distinguish between open and closed sliding roofs on a single-bay garage at an SS-25/27 mobile missile base.
- Identify propellant/warhead/oxygen (26-m), hydrogen (44-m), fuel and oxidizer containers/ canisters/tanks.
- Distinguish between mobile missile TELs and missile support vans in a known support base, when not covered by camouflage.
- Identify missile transporter vehicles with prime movers.

Rating Level 6:

- Identify individual SA-3, missiles on launchers.
- Identify an SA-2/CSA-1 transporter by overall configuration and details of chassis construction.
- Distinguish between SA-6 TEL and its associated STRAIGHT FLUSH radar when in travel mode.
- Identify mobile-tracked/wheeled SAM equipment by model (e.g., RS SA-6, SA-13, SA-9, SA-8; US-CHAPARRAL; FR-CROTALE; INT-ROLAND).
- Identify an SA-2 or CSA-1 missile by the presence and relative positions of wings and control fins.

Rating Level 7:

- Identify exhaust nozzle on an SA-5 solid fuel booster.
- Detect support bands on a SA-12 (types A and B) canister.
- Identify the hinge line on the control surface of sustainer fins of an SA-3.
- Identify a MOD III or IV SA-2 missile by sustainer fin tip chord variations.

Rating Level 8:

- Identify joints and welds on a TEL and radar.
- Identify seams, welds, joints, and construction lines on a No-Dong class medium-range ballistic missile.
- Identify factory markings on a missile canister to determine possible model number or dummy SA-5 missile.
- Identify screws and bolts on missile components.

Rating Level 9: not applicable.

Naval Order of Battle

Rating Level 1: not applicable.

Rating Level 2:

- Detect the presence of a large ocean-going vessel in open water.
- Detect a large shallow-water marina.
- Detect a mid-sized port facility.

Rating Level 3:

- Detect small boats (e.g., fishing vessels, small combatants, patrol boats).
- Distinguish between naval and civilian port facilities by type and configuration of large functional areas.
- Identify a dry dock at a known port facility.
- Identify a large surface ship in port by type (e.g., auxiliary ship, combatant, noncombatant/merchant).
- Identify aircraft carriers by the size of the ship and the shape of the deck.

Rating Level 4:

- Identify a Soviet ship as either a cruiser or a destroyer by its relative size and hull shape.
- Identify a TYPHOON in port or at anchorage.
- Determine if ship holds are open or closed.
- Detect aircraft on an aircraft carrier.
- Distinguish between a freighter and a tanker on the basis of equipment on deck.
- Identify cranes at a port by type (e.g., jib, gantry, shear leg).

Rating Level 5:

- Distinguish between fleet ballistic missile submarines and other classes of submarines (e.g., attack submarine, nuclear attack submarine, cruise missile submarine).
- Identify a KASHIN-class destroyer by the twin pair of square smoke stacks.
- Detect the presence of a medium-caliber bow gun on a destroyer.

Rating Level 6:

- Identify SAM launch tubes or canisters on combatants (e.g., SA-N-3 GOBLET).
- Detect a BANDSTAND communications system on a SOVREMENNYY-class ship.
- Identify missile tracking and control radars on guided missile cruisers/destroyers (e.g., RS – TOP DOME, FRONT DOME, KITE SCREECH).
- Identify the 12 individual hatch covers of inclined launched SA-N-6 forward of superstructure on KIROV [Soviet tank]-class.
- Identify individual gun barrels on a KIROV.
- Identify missile doors on cruise missile submarines, nuclear or fleet ballistic-missile submarines.

Rating Level 7:

- Detect the gun turret hatches.
- Detect the presence of personnel on deck.
- Identify individual posts and rails of protective railing around the perimeter of the deck.
- Identify the hull numbers on a Iranian COMBATTANTE IIB-class PTG [guided-missile patrol craft] (also known as: KAMAN P-227 SHAMSHIR).
- Identify detail on torpedo tubes (e.g., banding).
- Identify individual elements of weapons and electronics systems (e.g., feed horns, muzzle breaks, screens, feed mounts).
- Identify winch cables on deck-mounted cranes.
- Identify the configuration (e.g., shape, number of blades) of a submarine propeller in dry dock.

Rating Level 8:

- Identify mounting rings on the life support/rescue canisters.
- Identify ship's pendant number on life rings mounted on bulkheads.
- Identify individual rungs on between-deck ladders.

Rating Level 9: not applicable.

INFRARED NATIONAL IMAGERY INTERPRETABILITY RATING SCALE, APRIL 1996

Rating Level 0: interpretability of the imagery is precluded by obscuration, degradation, or very poor resolution.

Rating Level 1:

- Distinguish between runways and taxiways on the basis of size, configuration, or pattern at a large airfield.
- Detect a large (e.g., greater than 1 square km) cleared area in dense forest.
- Detect large oceangoing vessels (e.g., aircraft carrier, supertanker, KIROV) in open water.
- Detect large areas (e.g., greater than 1 square km) of marsh/swamp.

Rating Level 2:

- Detect large aircraft (e.g., C141, 707, BEAR, CANDID, CLASSIC).
- Detect individual large buildings (e.g., hospitals, factories) in an urban area.
- Distinguish between densely and sparsely wooded and open fields.
- Identify an SS-25 base by the pattern of buildings and roads.
- Distinguish between naval and commercial port facilities based on type and configuration of large functional areas.

Rating Level 3:

- Distinguish between large (e.g., C141, 707, BEAR, A300 AIRBUS) and small aircraft (e.g., FISHBED, L39).
- Identify individual thermally active flues running between the boiler hall and smokestacks at a thermal power plant.
- Detect a large air warning radar site based on the presence of mounds, revetments, and security fencing.
- Detect a driver training track at a ground forces garrison.
- Identify individual functional areas (e.g., launch sites, electronics area, support area, missile handling area) of an SA-5 launch complex.
- Distinguish between large (e.g., greater than 200 m) freighters and tankers.

Rating Level 4:

- Identify the wing configurations of small fighter aircraft (e.g., FROGFOOT, F-16, FISHBED).
- Detect a small (e.g., 50-m square) electrical transformer yard in an urban area.
- Detect large (e.g., greater than 10 m in diameter) environmental domes at an electronics facility.
- Detect individual thermally active vehicles in garrison.
- Detect thermally active SS-25 missile support vehicles in garrison.
- Identify individual closed-cargo hold hatches on large merchant ships.

Rating Level 5:

- Distinguish between single tail (e.g., FLOGGER, F-16, TORNADO) and twin tailed (e.g., F-15, FLANKER, FOXBAT) fighters.
- Identify outdoor tennis courts.
- Identify the metal lattice structure of large (e.g., approximately 75 m) radio relay towers.
- Detect armored vehicles in a revetment.
- Detect a deployed transportable electronics tower at an SA-10 site.
- Identify the stack shape (e.g., square, round, oval) on large (e.g., greater than 200 m) merchant ships.

Rating Level 6:

- Detect wing-mounted stores (e.g., air-to-surface missiles, bombs) protruding from the wings of large bombers (e.g., B-52, BEAR, BADGER).
- Identify individual thermally active engine vents atop diesel locomotives.
- Distinguish between a FIX FOUR and FIX SIX site based on antenna pattern and spacing.
- Distinguish between thermally active tanks and armored personnel carriers.
- Distinguish between a two-rail and four-rail SA-3 launcher.
- Identify missile tube hatches on submarines.

Rating Level 7:

- Distinguish between ground attack and interceptor versions of the MIG-23 FLOGGER based on nose shape.
- Identify automobiles as sedans or station wagons.
- Identify antenna dishes (smaller than 3 m in diameter) on a radio relay tower.
- Identify the missile transfer crane on an SA-6 transloader.
- Distinguish between an SA-2/CSA-1 and a SCUD-B missile transporter when missiles are not loaded.
- Detect mooring cleats or bollards on piers.

Rating Level 8:

- Identify the ram air scoop on the dorsal spine of FISHBED J/K/L.
- Identify limbs (e.g., arms, legs) on an individual.
- Identify individual horizontal and vertical ribs on a radar antenna.
- Detect closed hatches on a tank turret.
- Distinguish between fuel and oxidizer multisystem propellant transporters based on twin or single fitments on the front of the semitrailer.
- Identify individual posts and rails on deck edge life rails.

Rating Level 9:

- Identify access panels on fighter aircraft.
- Identify cargo (e.g., shovels, rakes, ladders) in an open bed, light-duty truck.
- Distinguish between BIRDS EYE and BELL LACE antennas based on the presence or absence of small dipole elements.
- Identify turret hatch hinges on armored vehicles.
- Identify individual command guidance strip antennas on an SA-2/CSA-1 missile.
- Identify individual rungs on bulkhead-mounted ladders.

RADAR NATIONAL IMAGERY INTERPRETABILITY RATING SCALE, APRIL 1999

Rating Level 0: interpretability of the imagery is precluded by obscuration, degradation, or very poor resolution.

Rating Level 1:

- Detect field delineation based on vegetation differences.
- Identify golf courses.
- Detect natural surface runways (e.g., grass, bare earth) in open terrain.
- Detect shoreline quays outside of a port facility in absence of ships.
- Detect vessel (~300 ft long) at suspected narcotics transshipment point in open ocean.

Rating Level 2:

- Identify natural drainage pattern in tidal flats.
- Detect extent of recent flooding based on soil moisture differences.
- Detect windbreaks/hedgerows between fields.
- Identify composition of runway/taxiways/parking aprons (e.g., concrete, asphalt).
- Detect wetland areas unsuitable for mobile ICBM traffic.
- Detect submerged spoil field from dredging operations near a port facility.
- Detect the presence of offshore surface vegetation along a beach LZ.

Rating Level 3:

- Distinguish between fallow and abandoned fields.
- Detect effluent discharge into water from industrial facility.
- Distinguish between an open pit coal mine and a limestone quarry.
- Identify large cargo aircraft as military or commercial based on paint color/scheme.
- Detect rows of vehicles in a parking area.
- Identify beach terrain suitable for amphibious landing operations.

Rating Level 4:

- Detect vegetation stress/aging in narcotics crops in reported eradication area.
- Identify tennis court composition (grass, clay, or rubber/composite).
- Detect CCD efforts (cut vegetation, camouflage netting) at suspected coca processing facilities.
- Identify azimuth markings (numbers) on runway.
- Detect tanks and self-propelled guns in revetted positions.
- Detect blast marks from mobile- or silo-based ICBM launches on concrete.
- Detect presence of sea land containers on a ship’s deck.
- Distinguish between coal and sand loaded onto a dumb barge.

Rating Level 5:

- Detect individual trees with indications of vegetation stress.
- Identify color of unfurled sails on sailboats (20 to 30 ft long).
- Distinguish between military and civilian helicopter paint schemes.
- Identify large ground forces' equipment by type (e.g., tanks, self-propelled guns, armored recovery vehicles).
- Detect foxholes by ring of spoil outlining hole.
- Detect the presence of sailors in formation on the deck of a large combatant during parade/ review.
- Identify colors of stripes/deck markings on major surface combatants.

Rating Level 6:

- Detect a foot trail through tall grass.
- Identify colored bands on rail cars.
- Identify support personnel performing maintenance while on an aircraft.
- Identify the colors of stack markings on merchant ships.
- Detect the presence of an algae line on the dark surface of a submarine hull.

Rating Level 7:

- Identify medium farm animals by type (e.g., sheep, hogs, goats).
- Distinguish road safety signs by color.
- Detect wing flaps and other articulating surfaces on fighter aircraft.
- Distinguish between open and closed hatches on the turret of an MTLB [Russian transport combat vehicle] chassis.
- Detect windsock on helicopter deck.
- Identify canvas covering the muzzles of an ADMG630 gun.

Rating Level 8:

- Detect different species of trees based on color variation.
- Detect a soccer ball in play at a sports field.
- Detect a person (with helmet) in a fighter aircraft with the canopy open.
- Identify turret-mounted smoke grenade dischargers on an M1 main battle tank.
- Detect color-pattern-of-life rings on surface vessels.

Rating Level 9:

- Identify rock layers in sedimentary outcropping.
- Identify and count cleats on a civilian ski boat.
- Detect red/green wing lights on fighter aircraft.
- Distinguish between armed soldiers and armed civilians based on clothing.
- Identify the draft marks numbers on submarine bows.

MULTISPECTRAL NATIONAL IMAGERY INTERPRETABILITY RATING SCALE, JANUARY 2001

Rating Level 0: interpretability of the imagery is precluded by obscuration, degradation, or very poor resolution.

Rating Level 1:

- Detect field delineation based on vegetation differences.
- Identify golf courses.
- Detect natural surface runways (e.g., grass, bare earth) in open terrain.
- Detect shoreline quays outside of a port facility in absence of ships.
- Detect vessel (~300 ft long) at suspected narcotics transshipment point in open ocean.

Rating Level 2:

- Identify natural drainage pattern in tidal flats.
- Detect extent of recent flooding based on soil moisture differences.
- Detect windbreaks/hedgerows between fields.
- Identify composition of runway/taxiways/parking aprons (e.g., concrete, asphalt).
- Detect wetland areas unsuitable for mobile ICBM traffic.
- Detect submerged spoil field from dredging operations near a port facility.
- Detect the presence of offshore surface vegetation along a beach LZ.

Rating Level 3:

- Distinguish between fallow and abandoned fields.
- Detect effluent discharge into water from industrial facility.
- Distinguish between an open pit coal mine and a limestone quarry.
- Identify large cargo aircraft as military or commercial based on paint color/scheme.
- Detect rows of vehicles in a parking area.
- Identify beach terrain suitable for amphibious landing operations.

Rating Level 4:

- Detect vegetation stress/aging in narcotics crops in reported eradication area.
- Identify tennis court as being composed of grass, clay, or rubber/composite.
- Detect CCD efforts (cut vegetation camouflage netting) at suspected coca processing facilities.
- Identify azimuth markings (numbers) on runway.
- Detect tanks and self-propelled guns in revetted positions.
- Detect blast marks from mobile or silo-based ICBM launches on concrete.
- Detect presence of sea land containers on a ship's deck.
- Distinguish between coal and sand loaded on dumb barge.

Rating Level 5:

- Detect individual trees with indications of vegetation stress.
- Identify color of unfurled sails on sailboats (20 to 30 ft long).
- Distinguish between military and civilian helicopter paint schemes.
- Identify large ground forces' equipment by type (e.g., tanks, self-propelled guns, armored recovery vehicles).
- Detect foxholes by ring of spoil outlining hole.
- Detect the presence of sailors in formation on the deck of a large combatant during parade/ review.
- Identify colors of stripes/deck markings on major surface combatants.

Rating Level 6:

- Detect a foot trail through tall grass.
- Identify colored bands on rail cars.
- Identify support personnel performing maintenance while on an aircraft.
- Identify the colors of stack markings on merchant ships.
- Detect the presence of an algae line on the dark surface of a submarine hull.

Rating Level 7:

- Identify medium farm animals by type (e.g., sheep, hogs, goats).
- Distinguish road safety signs by color.
- Detect wing flaps and other articulating surfaces on fighter aircraft.
- Distinguish between open and closed hatches on the turret of an MTLB chassis.
- Detect windsock on helicopter deck.
- Identify canvas covering the muzzles of an ADMG630 gun.

APPENDIX E
VIDEO NATIONAL IMAGERY INTERPRETABILITY RATING SCALE

The Video NIIRS is used to document the subjective quality scale for airborne motion imagery in the visible spectrum. When used in this context, "quality" refers to the interpretability or "intelligence value" of a video clip; it is not a measure of esthetic value. The Video-NIIRS is designed to account for differences in resolution, sampling rate (frame-rate), scene complexity, and human activity or behavior (see Motion Imagery Standards Board (MISB) Recommended Practice, Video-National Imagery Interpretability Rating Scale, RP0901.1, approved for public release, NGA Case 09-13715, June 2011).

SCALE DESIGN

The Video-NIIRS is designed to be log-linear in resolution space, meaning that each successive Video-NIIRS level from zero (lowest) to nine (highest) represents a halving of ground sampling distance (i.e., doubling the resolution from Video-NIIRS 3 to Video-NIIRS 4 and so on). It provides criteria tasks for the seven orders of battle or content domains: air forces, ground forces, electronics, missile, naval forces, culture, and security. Some Video-NIIRS levels have more than one criterion example per OOB/content domain.

Each written criterion contains specific components separated by a bullet point to add clarity and aid readers understanding of the content. These components are arranged for each criterion as follows:

- Analyst task. (Verbs like 'track' or 'confirm' infer an analyst's ability to do so consistently over an ensemble of clips of equal quality.)
- Object of interest.
- Associated activity or behavior.
- Environment.
- Object reference examples.

The analyst rates a video clip by determining if he or she can perform the most relevant criteria listed for a particular Video-NIIRS level, but cannot do the same for the next higher level. In other words, if an analyst can perform the Video-NIIRS 4 criteria on a video clip, but cannot perform the Video-NIIRS 5 criteria, the analyst rates the video clip Video-NIIRS level 4.

USING THE VIDEO NATIONAL IMAGERY INTERPRETABILITY RATING SCALE IN ANALYST EVALUATIONS

Video-NIIRS ratings are a measure of interpretability (intelligence value). The ability (or inability) to perform the tasks provided in Video-NIIRS criteria is either possible or it is not possible; therefore, the rating should be given using a whole number. There can and will be significant differences in the visual preferences an analyst may have regarding videos of the same Video-NIIRS rating level. While these preferences may be undefined, they are, by definition, not measures of interpretability. They do, however, represent human factors that can impact the quality of analysis and should be addressed.

These undefined visual preferences are not task based and can be assessed in quality studies using the double-stimulus continuous quality scale method described in International Telecommunications Union-Radiocommunication Sector BT.500-12, *Methodology for the Subjective Assessment of the Quality of Television Pictures*. Any study using Video-NIIRS to extract analyst ratings that are fractional or decimal in nature may not meet the criteria for construct validity.

MOTION IMAGERY DEFINED

Motion imagery is defined as imagery [a likeness or representation of any natural or man-made feature or related object or activity] utilizing sequential or continuous streams of images that enable observation of the dynamic, temporal behavior of objects within the scene. Motion imagery temporal rates are nominally expressed in frames per second and must be sufficient to characterize the desired dynamic phenomena. Motion imagery is defined as including metadata and nominally beginning at frame rates of 1-frame per second (expressed here in Hertz) or higher within a common field of regard. Full motion video falls within the context of these standards (see *Motion Imagery Standards Profile (MISP), version 6.4*).

VIDEO NATIONAL IMAGERY INTERPRETABILITY RATING SCALE CRITERIA BY QUALITY LEVEL

Video National Imagery Interpretability Rating Scale: Level 2

At Video-NIIRS level two, motion imagery data lacks sufficient spatial and/or temporal resolution for intelligence surveillance. For example, high EO-NIIRS still imagery would be rated Video-NIIRS two regardless of spatial resolution, as it provides no dynamic content. High frame-rate video of a resolution too low to discern most human activity would be rated Video-NIIRS zero because it provides insufficient spatial content.

Assuming a suitably wide field of view, gross spatial and temporal resolution motion imagery data could support monitoring of commercial sea lanes (tracking tankers and other large surface ships) as well as conducting macro-pattern analysis of populated regions. Such data may also support dynamic earth sciences, such as oceanography and meteorology.

Video National Imagery Interpretability Rating Scale: Levels 3–11

Table E-1 explains levels 3 through 11 of the Video-NIIRS, according to the Recommended Practice, Video-National Imagery Interpretability Rating Scale.

Order of Battle	Video NIIRS Level 3
AIR FORCES	Track movement of an identified heavy cargo/passenger aircraft during taxi or tow at a primary airfield/airport installation (aircraft length: 50 m or more, e.g., MD11, A300, B747, B767, DC8). Note: Under-resolved smaller aircraft may be evident based on movement or behavior.
ELECTRONICS	Track the movement of a convoy of unidentified radar/radar support vehicles in column formation or road march traveling on an open roadway in the vicinity of a known EW or SAM radar site (four to eight vehicles with total column length 50 m or longer). Note: Vehicles comprising the convoy and other under-resolved vehicles are evident based on movement or behavior.
GROUND FORCES	Track the movement of an unidentified military convoy company sized or larger consisting of armor or mechanized infantry in a column or “road march” on an open highway/roadway (four to eight vehicles with total column length 50 m or longer). Note: Vehicles comprising the convoy and other under-resolved vehicles are evident based on movement or behavior.
MISSILE	Track the movement of a convoy of ICBM transporter and support vehicles during deployment or road march on an improved road near missile base, launch site, or silo (Dong Feng 4, Taepodong 2, Agni V: transporter with support vans—convoy length 60 m or longer). Note: Support vehicles comprising the convoy and other under-resolved vehicles may be evident based on movement or behavior.
NAVAL FORCES	Track the movement of an unidentified coastal patrol craft conducting normal operations at sea several miles beyond a harbor or port (e.g., US Cyclone Class: average 58 m length, 8 m beam). Note: Under-resolved smaller craft may be evident based on movement, behavior, or wake.
CULTURE	Track the movement of an oversized heavy hauler tractor and trailer driving in a convoy on the open highway (movers of houses, cranes, drilling and large earth moving equipment), such as 100-ton, big-rig tractors with multiaxle lowboy special use trailer, total length 40 m to 50 m). Note: Under-resolved smaller trucks may be evident based on behavior.
	Track the movement of an oversized container carrying flatbed railcar in motion at a rail yard (46 m length flatbed rolling stock). Note: Under-resolved smaller trucks or rolling stock may be evident based on behavior.
SECURITY	Track the movement of an unidentified convoy of three or more sea/land containers driving in a column formation exiting a rail yard or port facility, such as big-rig tractors hauling sea/land containers, total convoy length 50 m or more. Note: Under-resolved smaller trucks may be evident based on behavior.

Order of Battle	Video NIIRS Level 4
AIR FORCES	Track movement of an identified large fighter/attack aircraft during taxi or tow at a primary airfield/airport installation (aircraft length: 15 m or longer; e.g., F-15, F-16, Eurofighter, F-22, MIG-29, F-35). Note: Under-resolved smaller aircraft may be evident based on movement or behavior.
	Confirm rotor wash effects of an unidentified light/medium helicopter on tall grass, sand, or dirt during takeoff or landing in the field, at a tactical LZ or forward arming and refueling point (diameter of disturbance: 25 m to 50 m). Note: The helicopter causing rotor wash, as well as other under-resolved aircraft or ground support vehicles may be evident based on movement or behavior.
ELECTRONICS	Confirm movement of large EW radar or signal intercept vehicles and vans with trailers in column/convoy or deploying at or near a known improved electronics site (large flatbed tractor-trailer with mast mounted antennas: 20 m vehicle length). Note: Under-resolved smaller vehicles (vans or cars) may be evident based on behavior.
GROUND FORCES	Track the movement of individual, tracked engineering vehicles and wheeled prime mover/trailer combinations during tactical road march/deployment in the field or on an unpaved road (e.g., engineer recovery vehicles, scissor bridges, tank carriers: average length 15 m to 25 m). Note: Under-resolved smaller vehicles (light trucks, support vehicles) may be evident based on behavior.
MISSILE	Track the movement of an individual ICBM while being transported overland on an improved road near missile base, launch site or silo (Dong Feng 4, Taepodong 2, Agni V: airframe length approximately 20–30 m). Note: Under-resolved smaller support vehicles may be evident based on behavior.
NAVAL FORCES	Track the movement of an unidentified small near-shore or inter-coastal patrol boat conducting normal operations in the coastal or near-shore littoral environment (e.g., US Mark V Special Operations Craft: approximately 85 ft in length, 6 m beam). Note: Under-resolved smaller boats may be evident based on movement, behavior, or wake.
	Track movement of an identified large fighter/attack aircraft during shipboard air operations on the deck of an attack aircraft carrier (aircraft length: 15 m or more, e.g., F-18, Harrier, F-35). Note: Under-resolved smaller aircraft or deck handling equipment may be evident based on movement or behavior.
CULTURE	Track the movement of a large freight/transport vehicle type: 18-wheel tractor-trailer rig, metro-bus, large recreational vehicle driving independently on an urban road in light traffic (commercial freight and public transports: 15 m to 23 m in length). Note: Under-resolved smaller vehicles (cars, sport utility vehicles) may be evident based on behavior.
SECURITY	Track the movement of an individual sea/land container tractor-trailer rig driving independently on a highway in light traffic (commercial freight transports: 15 m to 23 m long). Note: Under-resolved smaller vehicles (cars, sport utility vehicles) may be evident based on movement or behavior.

Order of Battle	NIIRS Level 5
AIR FORCES	Confirm rotation of main rotor blades on an identified medium helicopter during warm up or taxi at a primary airfield/airport installation (rotor-blade diameter: 12 m to 18 m; e.g., RAH66, KA50, AH64, NH90, UH60). Note: Under-resolved ground crew or grouped dismounts may be evident based on movement or behavior.
ELECTRONICS	Confirm movement of a large electronics vehicle's mast and mast-mounted antenna while being raised or lowered at a known improved electronics site (vehicle-/trailer- mounted mast and antenna: mast height 20 m or more). Note: Under-resolved crew members or grouped dismounts may be evident based on movement or behavior.
GROUND FORCES	Confirm the rotation of the turret on a main battle tank as the main gun slews during training, live fire exercise, or combat at a gunnery range, field deployment site, or battle zone (e.g., M1-A2, Challenger-2, Leopard-2, T-80: average chassis 9 m long by 3.5 m wide). Note: Under-resolved dismounts may be evident based on movement or behavior.
MISSILE	Track the movement of an individual mobile SRBM while being transported or during launch preparations on or near a road in the vicinity of a surveyed launch site (mobile Fajr-5 or SCUD: airframe length approximately 10 m to 15 m). Note: Under-resolved dismounts may be evident based on movement or behavior.
NAVAL FORCES	Track the movement of a light riverine/deep inter-coastal patrol boat during operations/patrol in the riverine environment (e.g., light patrol boat or rigid inflatable boat 8 m to 11 m long, 2.5 m to 3 m beam). Note: Under-resolved personal water-craft or swimmers may be evident based on movement, behavior, or wake.
CULTURE	Track the movement of a car, sport utility vehicle, van, or light truck driving independently on roadways in medium traffic (mid and full size cars and trucks: 5 m to 6 m in length). Note: Under-resolved two-wheeled vehicles or dismounts may be evident based on movement or behavior.
SECURITY	Track the movement of a suspect car, sport utility vehicle, or light truck driving erratically/aggressively or employing evasive driving measures on roadways in light traffic (mid and full size cars and trucks: 5 m to 6 m in length). Note: Under-resolved two-wheeled vehicles or dismounts may be evident based on movement or behavior.
Order of Battle	**Video NIIRS Level 6**
AIR FORCES	Confirm movement of control surfaces on an identified heavy cargo/passenger aircraft during preflight checkout or taxi at a primary airfield/airport installation (flaps and ailerons on aircraft having wingspan of 112 m or more; e.g., MD11, A300, B747, B767, DC8).
ELECTRONICS	Confirm the movement of a vehicle- or building- mounted parabolic mesh antenna as it slews or rotates at a known improved electronics site (e.g., parabolic mesh antennas, approximate diameter of 30 ft).
GROUND FORCES	Confirm the movement/operation of crew-served or vehicle-mounted antiaircraft systems as the launchers/guns slew to an aimed firing position during operation at a riveted, defensive field position (e.g., Avenger, Tunguska M1, Rapier: launcher pods average 2 m–3 m long).
MISSILE	Confirm the movement of vans, cranes/hoists supporting a mobile SRBM during maintenance, transloading, deployment preparation at a garrison or field maintenance facility (e.g., support vans and equipment lengths approximately 3 m to 5 m).

Order of Battle	Video NIIRS Level 6–Continued
NAVAL FORCES	Confirm the movement of a deck-mounted defensive armament as it slews and elevates to aim and fire on the surface combatant, cruiser, or frigate (e.g., 20 mm and 40 mm guns and mounts/ turrets, average diameter of 5 m to 6 m).
CULTURE	Track the movement of a full sized motorcycle driving independently on roadways in medium traffic (large cruising motorcycle, 2.5 m in length). Note: Under-resolved dismounts may be evident based on behavior.
SECURITY	Track the general movement of groups (25+) of under-resolved dismounts as they cross the street at a busy intersection in an open public square or pedestrian thoroughfare (i.e., commuters, shoppers, or event participants).
Order of Battle	**Video NIIRS Level 7**
AIR FORCES	Confirm the movement of control surfaces on an identified light transport aircraft during preflight checkout or taxi at an international or municipal airfield/airport installation (flaps and ailerons on aircraft having wingspan of 18 m or less; e.g., Beech Model 200 Super King Air, flaps approximately 0.75 m to 2.5 m in length).
	Confirm heat distortion waves/effects from the exhaust plume of a large fighter jet during warm up or taxi at a secondary/dispersal airfield (diameter of visible distortion approximately 5 m to 10 m).
ELECTRONICS	Confirm movement of large access panels as they are opened or closed on a site or field deployed electronics/radar van or mobile hut (individual panels of 2 m to 2.5 m diameter).
GROUND FORCES	Confirm the movement/operation of crew-served or vehicle-mounted antiarmor weapons as the launcher is aimed or slews to its firing position during live fire exercise or combat at a gunnery range, field deployment site, or battle zone (TOW 2, Milan, Javelin: launcher 1 m to 1.5 m in length).
MISSILE	Confirm the movement of the crew supporting a mobile SRBM during maintenance or launch preparations at a maintenance facility or launch site (individuals of average height and weight).
NAVAL FORCES	Confirm the movement of unidentified deckborne objects as they are dumped over the side or stern of any surface ship or fishing vessel at sea (e.g., container drums, bales, crab traps 2 m to 2.5 m diameter).
CULTURE	Confirm the movement of a car hood/bonnet or deck-lid/trunk/boot as it is opened or closed while stopped along a roadway or street (conventionally hinged midsize car hood or deck-lid).
SECURITY	Isolate pockets of unrest/potential violence in large groups (50+) of otherwise peaceful dismounts as they demonstrate or protest in an open public square or pedestrian thoroughfare (i.e., political demonstrators, bystanders, observers, security forces).
Order of Battle	**Video NIIRS Level 8**
AIR FORCES	Confirm the movement of individual pilot(s) or flight crew conducting external pre-flight checkout at a tactical/dispersal airfield or forward operating base (individuals of average height and weight).
ELECTRONICS	Confirm movement of individual crewmembers entering or exiting hatches or climbing ladders on a site- or field-deployed electronics/radar van or mobile hut (individuals of average height and weight).
GROUND FORCES	Confirm the movement of an individual holding a shoulder fired antiaircraft missile as the launcher is raised to the aimed firing position in the field, in a defensive position, or in the vicinity of an airfield or airport approaches (Stinger, SA-16/18-IGLA: launch tube average length is 1.7 m).
MISSILE	Track the movement of an individual member of a Katyusha rocket crew during transportation and deployment en route to/near a launch site (individuals of average height and weight).

Order of Battle	Video NIIRS Level 8–Continued
NAVAL FORCES	Confirm the movement of individual deck crew handling seaborne mines as they are readied for deployment off the stern of any surface ship/boat, especially a noncombatant modified/co-opted for terrorist or military use (seaborne mines, approximate 1 m in diameter).
CULTURE	Confirm the movement of a car door as it is opened or closed while stopped along a roadway or street (conventionally hinged midsized car door).
SECURITY	Isolate and track the movement of small subgroups (associates) in a larger crowd of people as they walk in an open public area or pedestrian walkway (i.e., subgroups of 2 to 5 individual pedestrians in a crowd of 20 or more, based on movement and proximity).
Order of Battle	**Video NIIRS Level 9**
AIR FORCES	Consistently track the movement of the body and arms of ground/flight crew member hand lock/unlock an external panel, hatch or compartment on any aircraft at any airfield or base (individuals of average height and weight).
ELECTRONICS	Consistently track the movement of an individual's body and arms while using an unidentified portable handheld communications device in an open public area or pedestrian walkway (individual of average height and weight holding device up to ear or bringing hands together for text entry).
GROUND FORCES	Consistently track the movement of the body and arms of an individual holding a long rifle or sniper rifle as the weapon is raised to an aimed firing position—either standing, sitting, or prone at a practice range, during live fire exercise, or during an engagement (e.g., Barrett M82-A1, Remington Model 700 series: 1 m to 2 m in overall length).
MISSILE	Consistently track the movement of an individual Katyusha crew member's body and arms during set up and launch preparation at a tactical launch site in a rural or urban environment (Individuals of average height and weight).
NAVAL FORCES	Consistently track the movement of an individual deck crew's body and arms as they conduct a patrol or operations on a light surface combatant; i.e., patrol boat (individual of average size and weight).
CULTURE	Consistently track the movement of a pedestrian's body and arms as he walks in a busy public area, market, or walkway (individual of average height and weight).
SECURITY	Confirm a conversation is underway based on the movement of the body and arms of participants as they walk or stand in an open public area or pedestrian walkway (i.e., subgroups of two to three individual pedestrians speaking among a meandering crowd of 20 or more).
Order of Battle	**Video NIIRS Level 10**
AIR FORCES	Confirm the movement of the hands and forearms of a ground crew/mechanic using an identified hand tool or power tool while servicing any aircraft or support vehicle at any airfield, base, or aircraft maintenance facility (individual of average size using socket wrench or power driver with length of 0.15 m to 0.3 m).
ELECTRONICS	Confirm movement of an individual's hands and forearms holding a visible handheld communications device in the process of sending/receiving information (e.g., speaking, text-messaging) in an busy public area or pedestrian walkway (cell phone or personal data assistant average diameter 0.1 m to 0.15 m).
GROUND FORCES	Confirm the movement of the hands and forearms of an individual holding a compact assault weapon or large frame handgun as the weapon is raised to an aimed firing position—either standing, crouched, or prone—at a practice range, during live fire exercise, or during an engagement (MP-5, AK74, Colt Commando, UZI, M-1911: 0.25 m to 0.8 m overall length).
MISSILE	Confirm the movement of an individual Katyusha crew member's hands and forearms while connecting leads/wires between rockets and trigger mechanism at a tactical launch site in a rural or urban environment (individuals of average height and weight).

Order of Battle	Video NIIRS Level 10–Continued
NAVAL FORCES	Confirm the movement of individual deck crew member's forearms and hands as he performs weapons check of pedestal mounted arms on a patrol boat in a riverine environment (individual of average size and weight manning a mounted .50 cal. or MK19 grenade launcher).
CULTURE	Confirm the movement of a pedestrian's forearms and hands as they make a purchase from a street vendor in a busy open market or square (individual of average height and weight, exchanging payment for goods).
SECURITY	Confirm an individual is speaking based on the movement of an individual's head and mouth as they engage in a conversation in an open public area or pedestrian walkway (i.e., determine if a person is speaking based on head and mouth movement).
	Confirm the movement of an individual's forearms and hands as they gesture or sign in an open public area or pedestrian walkway (i.e., confirm/read gestures or body language while subject is conversing, or partially interpret sign language).
	Confirm the functions of individuals based on the movement of body, head, forearms, and hands as a protected individual is moved to or from a vehicle/motorcade or in an open public area (i.e., isolate behavior to determine the function of individuals in a small group: armed security, principals, and VIPs).
	Confirm the exchange of a parcel based on the movement of the hands and forearms of two individual pedestrians as one walks past the other in a crowded public area or pedestrian walkway (i.e., confirm the exchange of a letter-sized envelope between two pedestrians in a crowd).
Order of Battle	**Video NIIRS Level 11**
AIR FORCES	Confirm the movement of the fingers/hand of a ground crew/mechanic changing the socket on a ratchet/socket wrench while servicing any aircraft or support vehicle at any airfield, base, or aircraft maintenance facility (socket able to fit in palm of workers hand).
ELECTRONICS	Confirm movement of an individual's mouth/jaw while speaking into a Bluetooth wireless mobile phone earpiece in a crowded public area or pedestrian walkway (average-sized person wearing an over the ear device with internal or boom microphone, average diameter: 2.5 cm to 5.0 cm).
GROUND FORCES	Confirm the movement of the fingers and hands of an individual holding a fragmentation grenade as the weapon's safety is released and the device is readied at a practice range, during live fire exercise, or during an engagement (spherical or cylindrical device, palm sized with metal pull ring/pin and spring loaded spoon: 6 cm to 8 cm diameter).
MISSILE	Confirm the movement of individual's fingers and hands while aiming a shoulder-fired antitank missile as they release safeties and arm the device at a tactical position in a rural or urban environment (individuals of average height and weight holding AT-4 or RPG).
NAVAL FORCES	Confirm the movement of an individual combat swimmer's hands and fingers as they check out and test scuba equipment on a light surface combatant; i.e., patrol boat near the littoral zone (individual of average size and weight).
CULTURE	Confirm the movement of a pedestrian's hands and fingers as they make change or sort coins in a busy open market or square (individual of average height and weight, sorting coins in a change purse or the palm of one hand).
	Confirm the movement of a pedestrian's hands and fingers as they communicate through sign language in an open public area (i.e., fully interpret sign language to include the spelling out of individual letters).

Order of Battle	Video NIIRS Level 11–Continued
SECURITY	Isolate and investigate an individual or group based on the movement of their hands, fingers, and face as they observe the movement of a protected individual from a crowd behind a rope line or police barrier (i.e., isolate behavior to determine if an individual or individuals pose an immediate threat to a VIP).
	Isolate and investigate an individual apparently burdened with significant concealed weight, based on his gait, posture, hands, fingers, and overall body language as he meanders into a crowd in a public square, market, or shopping mall (i.e., based on gait, determine if an individual is a public threat or concealing an explosive vest or belt).
	Isolate suspicious movement/behavior of the hands and fingers of a suspect individual or known operative as they leave an inconspicuous signal or message on a light pole or mailbox in a crowded urban street (i.e., traditional espionage tradecraft: a chalk mark or sticker on a predetermined location to signal a meeting or dead drop).

Legend:
cal–caliber
cc–cubic centimeter
LCAC–landing craft air cushion
VIP–very important person

(O) PART III. OTHER RESULTS

(P) Mission Requirements

(Q) Categorization of Target Entries. An introductory statement is written here categorizing a set of like items to increase readability. Defense Intelligence Agency Manual (DIAM) 57-5, *DOD Exploitation of Multisensor Imagery*, contains more detailed information on the structure of part III.

(R) PART IV. COLLECTION OBJECTIVES SATISFIED AND NOT SATISFIED

Paragraph Instructions for Initial Photographic Interpretation Report and Supplemental Photographic Interpretation Report Format

The following are instructions for completing each paragraph of an IPIR and SUPIR.

> ***Note:*** Information in parentheses is shown for explanation only. Line identification is not shown on an actual message. The IPIR/SUPIR/ multimission imagery photo interpretation report (MIPIR) format has been revised to accommodate the growth of automated intelligence systems. However, as a user's guide to understanding the reports, the following definitions are provided.

Cable Line.

References.

(A) Self-explanatory.

(B) Self-explanatory.

(C) Report type identifies the following:

- Reporting organization.
- Report number: reports will be numbered sequentially by the producing unit. (A two-character alpha unit identifier followed by a four-digit sequential number.)
- Reconnaissance project identification: Two characters indicating the project of which this mission is part. This stands for mission independent.
- Mission number.
- Date/time zone.

(D) General Mission Statement. Free text reporting information applying to the entire mission, such as graphic reference, sensors, sensor on/off times and coordinates, overall image quality, overall image scale range, other general mission data, or any other information deemed useful. If the objectives of the mission and the requesting authority can be given (consider length and classification), these will be included. The general mission statement will be written as the interpreted mission and appropriate data will be reported.

(E) Part I. MISSION HIGHLIGHTS. Title for first major division of the report.

(F) Textual Data for Mission Highlights. Part I, Mission Highlights allow for a concise free text statement of the significant information derived from the mission. It may be used to highlight individual items reported elsewhere in the message and to summarize information relative to a category of targets. Mission highlights may also be utilized for summations of trends of individual categories, such as logistic studies or combat information of a significant nature.

(G) Part II. SIGNIFICANT RESULTS. Title for second major division of the report.

(H) Categories of Items That May be Reported.

1. Perishable Items. This section is for items of perishable intelligence value, including transitory targets.

2. New Items. This section is for items upon which the reporting organization has no previous image-derived data.

3. Change and OOB Items. This section is for items that reflect significant changes since the last available interpretation and targets for which OOB is required. For DOD combat reconnaissance programs, this section includes mission requirement objectives. A mission objective could also be reported under perishable items of damage assessment.

4. Bonus Items. This section includes significant changes to any known installation that is not a specified mission requirement objective.

5. Damage Assessment. This section is for the description of damage to targets from nonnuclear attacks. This section includes known strike objectives not damaged.

(I) Identification data:

- Item number.
- Basic encyclopedia (BE) number or imagery basic encyclopedia number.
- Functional classification code. See DIA Publication 5210.002-M, *Standard Coding Systems Functional Classification Handbook*.
- Installation name or description of object imaged.

(J) Other identification data:

- Requirement number.
- Country code.
- Geographic coordinates.
- Universal transverse mercator coordinates.
- Military district. Entered when applicable.

(K) Status/activity data:

- NEG. Negated (nonexistent). Target/installation does not exist at or near the coordinates given in the requirement.
- UCO. Under construction.
- COM. Complete. The target/installation appears to be externally complete. Appears capable of operating but operational status cannot be determined.

- UNK. Unknown. Status of the target cannot be determined.
- NOP. Not operational. Essential elements of a target/installation are observed not to be in operation; equipment essential to the operation of the installation is either missing or observed as not to be operational.
- OPR. Operational.
- OCC. Occupied.
- DEC. Deception.
- UNP. Unoccupied.
- ABN. Abandoned.
- RMV. Removed. Target/Installation has been razed, dismantled, or moved.
- TRN. Transitory. Fleeting targets or targets that appear to be only temporarily situated.
- DMG. Damaged. Target is damaged to some extent, but it may be restored to usable condition.
- DST. Destroyed. Target is so damaged that it cannot function as intended or be restored to usable condition.
- CNA. Coverage not available.

Exploitation Level:

- AI - IPIR
- AS - SUPIR
- MI - MIPIR

Significance. The significance code indicates the interpreter's assessment of the degree of change in the installation status, capability, or function since previous mission coverage. If a significance code in entered, the reference mission number and date will be entered. Codes are as follows:

- NEW. Newly detected activity.
- SIG. Significant change has occurred.
- UNK. Significance of change is not known or change, if any, cannot be determined.
- NAC. No apparent change.

Reference Graphic. When a national basic reference graphic exists, the number may be required for specific programs. In all other cases, it will be left blank.

(L) Additional Interpretation Data. Additional photo interpretation data will be organized under one of the following codes:

- DES. Physical description. A DES will be accomplished when an installation is covered for the first time, a basic description of the installation has not been previously written, the installation reflects a significant physical change, or first reporting an installation as abandoned or destroyed.
- RMK. Remarks. This prefix will be used when providing less than a complete description of a known target/additional explanatory comments relating to status/activity. Only a DES or RMK

will be used for each entry, not both. If NAC is entered on the status line, a DES will not be used. The remark will include the project code and mission numbers of the coverage used to prepare the report in those cases where more than one mission is used. For MIPIR, the actual OOB count will be taken from a representative mission flown during the reporting period.

Order of Battle Designations:

- MIS. Missile and missile related equipment.
- AOB. Air OOB.
- NVL. Naval and merchant vessels.
- GFW. Ground force weapons and equipment.
- ELC. Electronic OOB.
- AAA. Antiaircraft OOB.
- DMY. Dummy.
- OBJ. Associated objects. Information relative to objects and equipment not reported under OOB entries.

Area Delineation. Refers to area delineation of the national basic reference graphic or other descriptive location data. When reference graphics are not available, location reporting is permitted (e.g., assembly area). Multicoverage dates may be included following each location entry or as unique entries.

(M) Imagery Reference Data (IMR). A minimum of one IMR line is required; however, more lines may be required to indicate different coverage. For MIPIR, only those missions that contributed to a specific degree are entered on the IMR line. Initial information in the IMR line may include date of coverage, project code, mission number, and camera station. The following coded items may then be used:

- IMR. Frame number.
- SLR. Side-looking radar.
- INF. Thermal.
- URG. Universal reference grid. Six position URG coordinates.
- AID. Additional imagery data. AID is used to provide interpretability data. Interpretability codes are as follows:
  - E-Excellent.
  - G-Good.
  - F-Fair.
  - P-Poor.

Extent of Coverage and Mode:

- A-Complete coverage/stereo.
- B-Complete coverage/partial stereo.

- C-Complete coverage/mono.
- D-Partial coverage/stereo.
- E-Partial coverage/partial stereo.
- F-Partial coverage/mono.

Type of Coverage:

- O-Oblique.
- V-Vertical.

Weather Conditions:

- CL-Clear.
- SC-Scattered.
- HC-Heavy Clouds.
- HA-Haze.

Other Conditions:

- SN-Snow.
- SH-Shadow.
- OL-Degrading obliquity.
- SD-Semidarkness.
- BL-Blurred image.
- TR-Terrain masking.
- HD-Heavy smoke/dust.

Type of Film:

- B-Black and white.
- C-Natural color.
- G-Green record.
- I-Color rear infrared.
- R-Red record.
- T-Thermal.
- S-Radar.
- N-Nonstandard.

> ***Note:*** For stereo or partial stereo, two letters will be used, one for the first frame and one for the second frame; e.g., BB, black and white on both frames.

- FRM. Additional frame reference for a given target.
- TOT. Time on target.
- IDC. Imagery derived coordinates, derived from comparing imagery with a map or chart.
- MPR. Map reference.
- PPC. Precision photo derived coordinates.

(O) Part III. OTHER RESULTS. Third major division of the report, as indicated by the sample; part III may be omitted.

(P) Mission Requirements. Provides for reporting items/targets not properly placed in part II.

(Q) Categorization of Target Entries. The format in part IV will contain collection objectives satisfied and not satisfied, plus a textual statement indicating any reasons for nonsatisfaction. Items contained in part IV can be understood from the codes listed earlier.

(R) Part IV. COLLECTION OBJECTIVES SATISFIED AND NOT SATISFIED. Part IV of the format will contain collection objectives satisfied and not satisfied, plus a textual statement indicating any reasons for nonsatisfaction. Items contained in part IV can be understood from the codes listed earlier.

APPENDIX G
EXAMPLE OF A MARINE UNMANNED AERIAL VEHICLE SQUADRON EQUIPMENT AND PERFORMANCE CHARACTERISTICS

SHADOW UNMANNED AIRCRAFT SYSTEM

The Shadow UAS consists of the following:

- Shadow UAS aircraft (see fig. G-1 on page G-2).
- Ground control station (see fig. G-2 on page G-2). The ground control station provides control of air vehicle and payload out to 125 km.
- Pneumatic launcher (see fig. G-3 on page G-3).
- Portable ground control station.
- Ground data terminal tracking system consists of track control unit on a pedestal antenna assembly and an interrogator unit. This system provides communication between aircraft and ground control station.
- Tactical automatic landing system. The airborne system consists of transponder onboard aircraft. This system provides for automatic landing guidance and control of the aircraft.
- Portable ground data terminal.
- Remote video terminal.
- Modular mission payload.

Figure G-1. Shadow Aircraft with Unmanned Aircraft System.

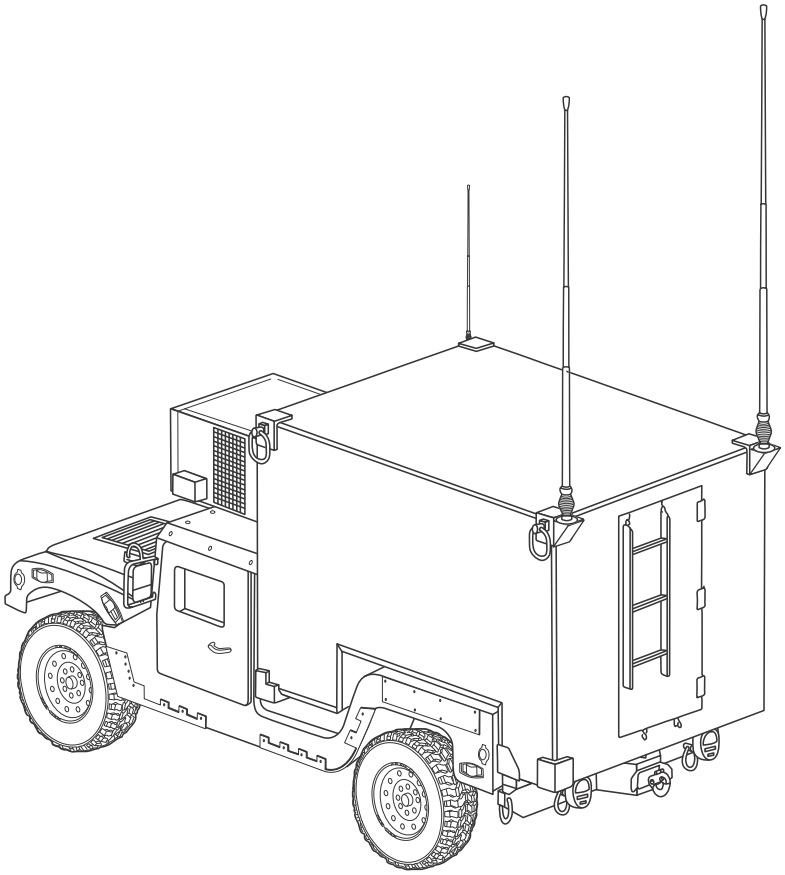

Figure G-2. Shadow Ground Control Station.

SHADOW UNMANNED AIRCRAFT SYSTEM CHARACTERISTICS

Figure G-3. Shadow Unmanned Aircraft System on Pneumatic Launcher.

Table G-1. Shadow Unmanned Aircraft System Characteristics.

Engine Limitations	
Maximum Operational	8,000 RPM for 2 minutes
Maximum Continuous Climb	7,800 RPM
Maximum Continuous Cruise	7,500 RPM
Minimum In-Flight	3,800 RPM
Maximum Static Full Throttle	7,200 RPM
Minimum Static Full Throttle	6,300 RPM
Rotor Temperature Operating Range	64°C–175°C
Maximum Continuous Cylinder Head Temperature	259°C for 2 minutes in a climb
Maximum Transient Cylinder Head Temperature	249°C
Minimum Cylinder Head Temperature	80°C
Static Idle RPM (Payload and IFF On)	3,600 RPM–3,840 RPM
Bus Voltage	
Bus Voltage (with engine operating)	26V–30 volts
Battery Fail	less than 19 volts
Airspeed Limitations	
TALS Automatic Abort High	78 kts for 2 seconds
TALS Automatic Abort Low	52 kts for 2 seconds
Low Airspeed Alert	55 kts
Turbulence (Rough Air)	70 kts
Maximum Airspeed Limits	60 kts–110 kts
Altitude Envelope	
Minimum Safe FTS Deploy	1,000 ft AGL
Minimum Altitude	Electric line of sight
Service Ceiling	15,000 MSL
Maximum Launch Altitude	9,000 density altitude
Wind Limitations (Takeoff and Landings)	
Maximum Headwind/Crosswind	20 kts gusting 25 kts
Maximum Tailwind For Launch	IAW maximum tailwind for launch and minimum precharge pressure tables
Maximum Tailwind Upon Selecting “Land AV”	0 kts
Maximum Tailwind During TALS Auto Recovery	5 kts

Legend:
AV–air vehicle
AGL–above ground level
°C–degrees Celsius
FTS–flight termination system
IAW–in accordance with
IFF–identification, friend or foe
kts–knots
MSL–modified surf limit
RPM–revolutions per minute
TALS–tactical automated landing system

Note: Designate minimum mandatory items for immediate requests. An * indicates use as applicable or when known. The format provided has been published as STANAG 3277 and has been approved by NATO as a

standard format for aerial requests. The letters A through K have special significance for certain organizations and are purposely omitted. When submitting message JTAR/S, the paragraph headings are not required, but the alpha-numeric paragraphs will not be changed. Instructions for completing a JTAR/S follow in this appendix.

Paragraph Instructions

The following are instructions for paragraphs L through U of a JTAR/S request.

L. REQUEST NUMBER: As directed.

A&C Priority: Use numerical designation below to define the tactical urgency for preplanned and immediate requests.

PRIORITY: It is the responsibility of the requestor to establish the priority.

Priority No.	Definition:
1	Takes precedence over all other requests except previously assigned Priority 1 requests. The results of these requests are of paramount importance to the immediate battle situation or objective.
2	The results of these requirements are in support of the general battle situation and will be accomplished as soon as possible after Priority 1 requests. These are requested to gain current battle information.
3	The results of these requests update the intelligence database but do not affect the immediate battle situation.
4	The results of these requests are of a routine nature and will be fulfilled when the reconnaissance effort permits.

M. DATE/TIME FACTORS

1. Self-explanatory.

2. State the TOT only when required and justify U2.

3. Indicate the LTIOV, if it is a factor. Deliver prior to this date/time.

4. Self-explanatory.

N. TYPE RECONNAISSANCE REQUESTED

1. Type of Mission (self-explanatory).

2. Type of Coverage.

   a. Pinpoint (self-explanatory).

   b. Strip/LOCs (search continuous photography of a route of LOC).

   c. Route Reconnaissance (visual reconnaissance of a route of LOC with photo of targets of military significance).

d. Area Search (visual search of a specified area with photos of targets of military significance).

e. Area Coverage (photographic coverage of a specified area).

f. Afloat (reconnaissance of vessels afloat).

Numbers 3, 4, and 5 are self-explanatory. These lines should be left blank unless it is fully understood what the selected sensor, photo, and film can accomplish.

O. MAP REFERENCE (self-explanatory).

P. TARGET COORDINATES. Provide reference system used and indicate actual coordinates.

Q. TARGET CATEGORY/PRIORITY INTELLIGENCE REQUIREMENT(S). Provide the appropriate category and indicate the desired PIR by selecting the number(s) from the target list category below.

CATEGORY 1—AIRFIELD

A. Activity: number, type, and location of aircraft.

B. Runways: number, orientation, and surface type.

C. Taxiway and parking areas: location and shape.

D. POL: number, size, and location.

E. Ammunition storage areas: number and location.

F. Hangars: number, size, and type of construction.

G. Electronic facilities: number, type, and location.

H. Defenses: number, type, and location.

I. Other: (specify).

CATEGORY 2—ARMOR/ARTILLERY/TROOPS/VEHICLES

A. Type: infantry, armor, engineering, artillery, etc.

B. Number and type of vehicles.

C. Number and type of armor.

D. Number and type of artillery.

E. Activity: direction of movement, dug in, etc.

F. Terrain: description.

G. Other: (specify).

CATEGORY 3—BRIDGE

A. Purpose: flood, rail, over road, etc.

B. Type: railroad, vehicular, agricultural, etc.

C. Construction: wood, steel, concrete, etc.

D. Construction: piers, abutments, approaches, stringers, beam, truss, etc.

E. Number of spans.

F. Length and width (height if significant).

G. Number of lanes/tracks.

H. Bypass in vicinity of bridge.

I. Activity.

J. Other: (specify).

CATEGORY 4—DEFENSIVE POSITIONS/STRONG POINTS/GUNS

A. Type and size of position or fortification.

B. Type weapons: number.

C. Fire control system.

D. Supporting positions.

E. Transportation access.

F. Routes of ingress and egress.

G. Nature of surrounding terrain and foliage barriers.

H. Activity.

I. Other: (specify).

CATEGORY 5—ELECTRONIC SITE

A. Type of site: microwave relay, EW, etc.

B. Antennas: number and type.

C. Mobile or permanent.

D. Primary buildings and support equipment.

E. Activity.

F. Security measures.

G. Size of area.

H. Other: (specify).

CATEGORY 6—HARBOR/PORT FACILITIES

A. Type port: maritime or inland waterway.

B. Activity.

C. Berthing and cargo handling facilities.

D. POL facilities: type, number, and locations.

E. Storage facilities.

F. Shipbuilding and repair facilities.

G. Transportation.

H. Defenses.

I. Other: (specify).

CATEGORY 7—INDUSTRIAL SITE

A. Type of industry.

B. Size of area.

C. Buildings: number, size, and construction.

D. Open storage: quantity by type.

E. Activity.

F. Transportation facilities.

G. Source of power.

H. Defenses.

I. Other: (specify).

CATEGORY 8—LINE OF COMMUNICATIONS

A. Type: road, rail, canal, etc.

B. Description of the route.

C. Chokepoints.

D. Significant activity.

E. Significant static targets.

F. Other: (specify).

CATEGORY 9—MILITARY INSTALLATIONS/STORAGE AREAS

A. Function: assembly, administration, barracks, depot, etc.

B. Activity: number of vehicles and/or personnel.

C. Size of the area.

D. Number of buildings: predominant construction only.

E. Storage: type and location.

F. Transportation.

G. Defenses.

H. Other: (specify).

CATEGORY 10—MISSILE SITE

A. Type.

B. Launch site: mobile/fixed, number of pads, etc.

C. Number and orientation of launchers/number loaded.

D. Control center: location and construction.

E. Number, type, and location antenna(s).

F. Auxiliary equipment.

G. Activity.

H. Defenses.

I. Other: (specify).

CATEGORY 11—POWER PRODUCTION FACILITY

A. Type: nuclear, coal, oil, hydroelectric, etc.

B. Size and construction.

C. Boiler/generators: number and location.

D. Transformer yard: size and location.

E. Cooling towers: number and location.

F. Penstock/turbine outlet (hydroelectric).

G. Activity.

H. Defenses.

I. Other: (specify).

CATEGORY 12—RAILROAD YARD

A. Type: classification, repair, other.

B. Length and width: chokepoint to chokepoint.

C. Number of tracks.

D. Facilities: repair shops, roundhouses, other.

E. Rolling stock.

F. Defenses.

G. Other: (specify).

CATEGORY 13—SHIPS

A. Class/type/number.

B. Heading/movement.

C. Nationality.

D. Identification.

E. Cargo.

F. Activity.

G. Other: (specify).

CATEGORY 14—OTHER

Narrative report is rendered under this heading in sufficient detail to ensure that the request or purpose of the mission is satisfied.

R. REPORTS.

1. In-flight report to friendly units.

2. Mission report of the results and significant sightings gathered.

3. Reconnaissance exploitation report, a brief, concise, high priority report on time-sensitive targets of significant tactical importance of a perishable nature.

4. IPIR that contains intelligence on mission objectives and additional significant intelligence.

5. SUPIR that provides detailed intelligence acquired through a comprehensive study of imagery.

S. IMAGERY PRODUCTS (specify type and quantity of imagery products required. Only mission essential imagery products should be requested).

T. DELIVERY ADDRESS.

1. Unit (delivery address for mission essential imagery products).

2. Air drop (coordinates, call sign, frequency, and run-in heading for aerial delivery of imagery products).

U. REMARKS/SPECIAL INSTRUCTIONS.

1. Target area control (indicate, when applicable, the call sign and radio frequency of the control element. Control of the mission will require close coordination with ground forces).

2. Other (self-explanatory, use this space to specify scale if required and to request specific TOT).

APPENDIX I
TARGET FOLDERS

A target folder contains intelligence that provides the location and components of a target or target complex and indicates its vulnerabilities and relative importance. It also contains related materials prepared for planning and executing actions against a specific target. A major prerequisite for starting a target folder is the relative degree of permanence of the potential target. In addition, local command SOPs will provide guidance as to targets needed to have folders maintained.

IMAGERY ANALYSIS

Imagery intelligence is often the definitive information source of intelligence support to targeting. Imagery intelligence input is reliable, accurate, and current and often forms the basis for targeting decisions. Imagery analysis is a vital component in the tactical and strategic targeting process. It is often the imagery analyst, during the analysis of imagery, who—

- Discovers potential targets and draws them to the attention of the command (CMD section).
- Conducts the target study that is an analysis of the proposed target from imagery and other pertinent sources.
- Takes the information provided by the target analysis and puts it into a target folder format.

TARGET ANALYSIS

The ISC is responsible to the AC/S G-2 for imagery intelligence efforts supporting the MEF's targeting process. Before a possible target can be selected for possible engagement, it must be developed such that its composition, strengths, and vulnerabilities are well known.

The analysis of a target requires the collection and evaluation of many items of information. The target folder is an instrument for the compilation and organization of relevant data produced by the target analysis. Decisions by the force fires coordinator and fire support coordinators regarding whether to attack a proposed target and which weapon system to select are critically influenced by the information in the target folder.

Once a possible target has been identified and approved for inclusion in the target intelligence data base, the imagery analyst and all-source intelligence analysts will prepare a target folder.

This analysis presents all available pertinent information on the proposed target from the following sources:

- *Reference materials*. Perform a thorough check of all available intelligence reference materials, such as interrogation, counterintelligence, ground reconnaissance, and SIGINT reports. All may be useful.
- *GEOINT*. Ensure current maps (latest editions) and other GEOINT materials of the target area are available.
- *Mission coverage*. Examine comparative coverage of the target area from past and ongoing imagery collections missions. If the latest available coverage is old, incomplete, poor quality, or the installation is under construction or renovation, then new collection missions may be required.

Specifications

A target folder is a reference file on permanent potential targets in the AO and AOI that has been created and maintained by the unit. It contains the results of the target study (analysis) and any updates or collateral intelligence. Target folders—

- May be used as a pre-mission briefing aid for aircrews to orient them on target location, recognition, defenses, and obstacles. Imagery analysts may use target folders strictly as reference files on important intelligence targets within the unit's AO. Such folders can be compiled to show an installation's development or an enemy unit's organization.
- Have common characteristics and contain a minimum of important elements.
- Are for permanent targets. A permanent C2 node, troop training area, warehouse area, port facility, or fixed missile site is a good potential target for target folders. Temporary targets, such as troops in the field, supply dumps, and ships in port or truck convoys, are usually not proper subjects for target folders.
- Are current. Because the information within a target folder may be used for target planning, it must be kept current. The target folder must be updated to reflect changes in defenses, physical characteristics, unit reorganization, important equipment, and so on.
- Are concise. Target folders are compact; only intelligence and other information pertinent to the commander's PIRs or intelligence requirements are included.
- Are accurate. Intelligence and other information within a target folder must be accurate to allow realistic targeting plans to be made. Answers to intelligence requirements must be specific to provide maximum value. For example, explicitly describe enemy defenses, target dimensions, shape, construction, use, and capacities.

> ***Note:*** Target folders should be reviewed periodically—or with each new imagery mission (intelligence priorities, resources, and time permitting)—and their contents should be checked against new information or intelligence requirements.

Format and Components

Enclosure F of CJCSI 3370.01, *Target Development Standards*, provides standards for developing electronic target folders (ETFs), hard copy target folders, and target materials.

Marine Corps imagery analysts will adhere to these guidelines and, within technological limitations, provide a product tailored to meet all supported commanders' target intelligence requirements. Although the contents of a target folder may vary slightly according to unit SOP, they will be in accordance with the Military Targeting Intelligence Committee guidelines and contain, at minimum, the following components:

- Heading.
- Target summary.
- Supporting materials.
- Weaponeering support.
- Assessment.
- Associated/collocated targets.
- Objectives and guidance.
- Folder notes/other related information.

Electronic target folders may be expanded to meet specific MAGTF or unit requirements. Additional information, such as supplemental graphics, vector (shapefile) overlays, capability specific supporting materials, three dimensional graphics, and other analytical or source documentation, may be entered into the ETF. The structure of ETFs will be standard across all target types and is intended to support use by all CCMDs, Services, CSAs, and allied producers in a joint/combined environment. Enclosure F of CJCSI 3370.01 provides details on ETF structure and content.

Heading. The heading contains the general identification details for each target entity and will include the following information:

- Classification and release (self-explanatory).
- Entity identifier (EID). (Use the EID, such as the BE number or communications transmission identifier, for the entity from the modernized integrated database [MIDB], when available. If an MIDB EID is not available, the target analyst must coordinate with the appropriate responsible analytic center to obtain a suitable unique EID.)
- Name. (Use the entity [i.e., facility] name as it appears in MIDB. If no record is available, the target analyst must liaise with the appropriate responsible analytic center to develop a suitable name using an approved naming convention.)
- Category and function code:
  - Installation/facility. If available, use the category code from the MIDB or consult DIA Publication 5210.002-M, which contains the complete numbering breakdown.
  - Other entity types (See appendix B to enclosure E of CJCSI 3370.01.).
- O-suffix (facilities only) (as assigned by MIDB).
- Location:
  - Latitude/longitude.
  - Military grid reference system.
  - Datum.

- Country code. (Use the country code from MIDB.)
- Original production date/last update. (Note the year, month, and day the ETF was produced or last updated in a nine-digit format, e.g., YYYYMMMDD.)

Target Summary. The target summary has the following characteristics:

- *Significance statement (basic)*. Use the data from the MIDB to state the significance of the target. For example, "Destruction of this target will deny the enemy 100,000 barrels of POL."
- *Target description (intermediate)*. Producers will identify the target type and provide a comprehensive description of the target, including any EEIs and any associated critical elements.
- *Functional characterization (intermediate)*. This statement elaborates on the function of the target.
- *Expectation statement (intermediate)*. When feasible, use data from MIDB.
- *Collateral concerns (intermediate)*. For facility/installation target types, if the nearest collateral object falls within the collateral damage estimation (CDE) level 1 collateral effects radius, it must be functionally characterized and identified by distance and direction from the target. The CDE is documented in the weaponeering section of the ETF.

Supporting Materials. At minimum, all ETFs produced on installations or facilities will include both an installation outline graphic and a facility (O-suffix) outline graphic. All details and supporting examples of imagery required form ETFs are detailed in appendix D, enclosure F of CJCSI 3370.01.

Weaponeering Support. Weaponeering support will include the following information:

- *Aimpoint (advanced)*. An aimpoint is a weapon placement term that applies to a variety of capabilities (e.g., a joint desired point of impact is a type of aimpoint).
- *Unique target characteristics*. The EFT should provide a detailed description of unique target/element/aimpoint or joint desired point of impact characteristics that would support weaponeering for all weapons/weapon types.
- S*uggested weaponeering solutions (advanced)*. Force fires center or FSCC personnel will complete in this section.
- *Collateral damage estimate*. The CDE will be accomplished in accordance with CJCSI 3160.01A, *No-Strike and the Collateral Damage Estimation Methodology*. The force fires center or FSCC personnel will complete in this section.

Assessment. At minimum, the assessment section will include areas for physical damage/change and functional damage assessments.

Physical Damage/Change Assessment. Physical damage assessment estimates the quantitative extent of physical damage (through munitions blast, fragmentation, and/or fire damage effects) to a target resulting from the application of military force. (JP 1-02) Change assessment is the identification and assessment of measurable change/damage to the target resulting from nonlethal methods or weapons.

Functional Damage Assessment. Functional damage assessment estimates the effect of military force to degrade or destroy the functional or operational capability of the target to perform its intended mission and on the level of success in achieving operational objectives established against the target. (JP 1-02)

Munitions Effectiveness Assessment. The munitions effectiveness assessment is the assessment of the military force applied in terms of the weapon system and munitions effectiveness to determine and recommend any required changes to the methodology, tactics, weapon system, munitions, fusing, and/or weapon delivery parameters to increase force effectiveness. (JP 1-02)

Reattack Recommendation. The reattack recommendation is an assessment that is derived from the results of the BDA and munitions effectiveness assessment, providing the commander systematic advice on reattack of targets and further target selection to achieve objectives. The reattack recommendation is a combined operations and intelligence recommendation.

Associated/Collocated. The associated/collocated section provides a textual list of entities collocated to the primary installation or facility that the ETF was produced to support. At minimum, this list should provide a name, BE number, category code, O-suffix, and coordinates for each entity. These entities could include, but are not limited to, the following:

- Units.
- Equipment.
- Facilities.
- Individuals/personnel.
- Groups/organizations.
- Resources.

Objectives and Guidance. The objectives and guidance section should include any associated strategic, operational, or tactical objectives or tasks related to the target on which the ETF was produced. This section should also include target damage and change objectives for the target.

Related Information. The related information section is an open section for additional information or intelligence that targeteers assess as important to complete or augment the ETF.

APPENDIX J
NATIONAL IMAGERY TRANSMISSION FORMAT COMPRESSION

COMPRESSION BASICS

Compression is a process used to decrease imagery file sizes so that usable images can be transmitted as quickly as possible. The national imagery transmission format (NITF) uses Huffman coding which is statistically based and produces a single code for each symbol. Coding varies the length of the symbol in proportion to its information content. Symbols with a low probability of appearance are represented with a code consisting of many bits. Conversely, symbols with a high probability of appearance are represented with a code of fewer bits. Most compression applications are designed with predetermined quality settings. These settings are referred to as Q settings or Q levels. The lower the Q setting is, the greater the compression and, therefore, the greater potential loss of image quality.

Joint Photographic Experts Group Image Compression

Joint Photographic Experts Group (JPEG) image compression is one of the most popular and widely used compression algorithms. It was adapted for use in the NITF in the early 1990s. The complete specifications are contained in MIL-STD-188-198A, *Joint Photographic Experts Group (JPEG) Image Compression for the National Imagery Transmission Format Standard*. National Imagery Transmission Format JPEG's forward discrete cosine transform (FDCT) is a mathematical formula that divides the image into 8 by 8 minimum coding units or neighborhoods and then calculates the FDCT of each neighborhood. The quantizer *rounds off* or *smoothes* the FDCT coefficients according to the table specifications, and then the image is encoded.

For decompression, JPEG recovers the quantized FDCT coefficients from the compressed data stream, computes the inverse transform (using embedded tables), and displays the image. This description is simple; technical details are in the military standard. It is important, though, to understand how the various Q settings impact the quality of an image and the time available to transmit the compressed image.

The NITF JPEG provides several variants—discrete cosine transform (DCT) lossy (8- and 12-bit), downsample JPEG, and lossless.

Discrete Cosine Transform Lossy. In lossy compression some quality is sacrificed for increased compression ratios. When users employ DCT lossy, they can choose from five different Q levels (Q1–Q5). Level Q1 provides the greatest compression and, therefore, the greatest quality loss; while, Q5 provides the least compression and, consequently, the highest image quality (see table J-1).

Table J-1. Discrete Cosine Transform Joint Photographic Experts Group Results Summary.

Image	Original	Q1	Q2	Q3	Q4	Q5
Color	1:1 12:11	43:1 00:13	34:1 00:15	16:1 00:36	12.6:1 00:44	8.7:1 01:04
B&W	1:1 58:18	13.9:1 04:10	11.8:1 04:54	8:1 07:14	7:1 08:16	5.4:1 10:37
IR	1:1 08:32	43.6:1 00:11	33.9:1 00:15	25.9:1 00:19	14.6:1 00:35	5:1 01:35
SAR	1:1 13:21	9.9:1 01:20	7:1 01:53	6:1 02:10	4:1 03:03	2:1 06:11
UAS	1:1 17:05	25:1 00:39	17.9:1 00:57	17:1 00:59	8.7:1 01:57	2.5:1 06:41
Multi-spectral	1:1 21:50	17:1 01:16	10.5:1 02:04	6:1 03:36	3.8:1 05:41	2.1:1 10:23
Compression ration (n:1) Time to Transmit (mm:ss) @ 9600 bits per second						

Legend:
B&W–black and white
IR–intelligence requirement

Downsample Joint Photographic Experts Group. Downsample JPEG uses a compression technique that is essentially the same DCT JPEG compression applied to an image that has been downsampled. This means that the image size has been reduced by discarding image data. This process is illustrated in the figure J-1: the original 2,048 x 2,048 size is downsampled to 1,024 x 1,024 and then to 512 x 512. In this process the algorithm selectively throws away image data in both the X and Y axes to reach the next smaller file size until the smallest is reached. In the reverse process (upsampling), the image is restored to its original size.

Lossless Joint Photographic Experts Group. Lossless data compression techniques will generate exact duplicates of input data streams (or original images) once the data has been compressed. In other words, the data stream (or image) is decompressed back into its original form with no differences to be found. However, lossless compression rates are very small (approximately 2:1 or 2.5:1) and offer no significant reduction in image file sizes.

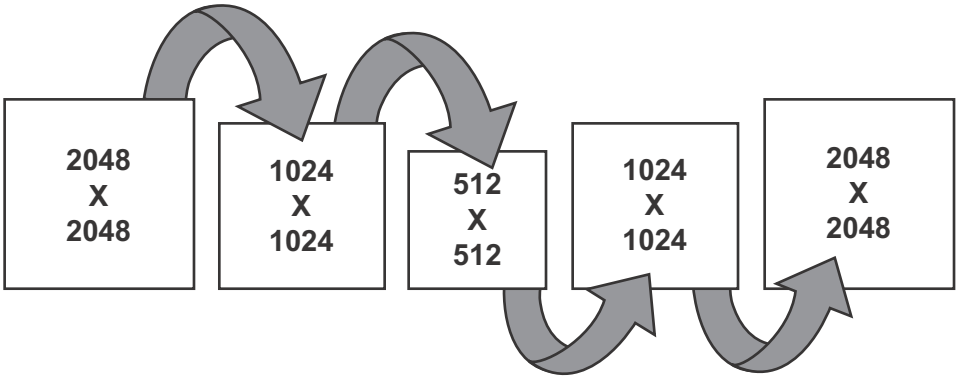

Figure J-1. Downsample and Upsample Process.

Bi-Level Image Compression

The NITF handles textual information as well. Bi-level compression uses the same algorithm that is used in commercial facsimile devices. If users must learn more about this type of lossless compression or facsimile devices, MIL-STD-188-161, *Interoperability and Performance Standards for Digital Facsimile Equipment*, and MIL-STD-188-196, *Department of Defense Interface Standard: Bi-Level Image Compression for the National Imagery Transmission Format Standard*, contain relevant technical information. The NITF implementation of bi-level compression provides three different modes of operation: mode 1 (one-dimensional coding); mode 2 (two-dimensional coding with standard vertical resolution), and mode 3 (two-dimensional coding with higher vertical resolution) (see fig. J-2). It is not necessary to know the details of bi-level compression. Users only need to know that the fundamental concept of this coding algorithm is to detect run lengths of one of two colors (for example, black or white) in an image. These run lengths are then replaced with Huffman codes. Synchronization codes that indicate the beginning of an image, the end of a line, or similar information are embedded.

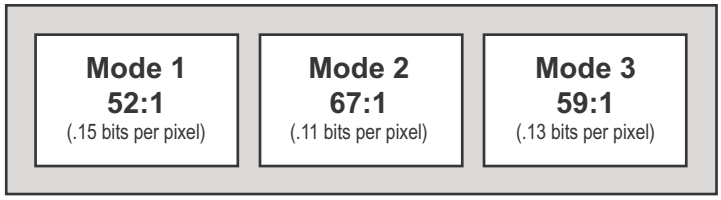

Figure J-2. Bi-Level Image Compression Results.

Video Compression

Motion imagery (or video imagery) is defined as imaging sensor/systems that generate sequential or continuous streaming images at specified temporal rates (normally expressed as frames per second). This type of imagery includes EO (video and television), infrared, complex waveforms based on radar imaging, MTI, and acoustic waterfalls. It is not within the scope of this publication to address all of these technologies, but it is necessary to know of their existence and that the NGA has published *MISP version 6.4*. This profile summarizes the results of work accomplished by the DOD/IC/NSG Motion Imagery Standards Board. The profile identifies MPEG [Motion Picture Expert Group]-2 as the standard video compression format. Additionally H.264 shall be the standard for applications constrained by low bandwidth channels (typically less than 1 megabyte per second that may not be adequately supported by MPEG-2). The MISP also allows the use of H.264 for higher bandwidth applications.

National Image Compression

The following are some of the items that are different in the national image compression arena:

- National compresses 8-, 11-, and 12-bit imagery data using both JPEG lossy and JPEG lossless compression (as well as other non-JPEG compression algorithms). The compressed data is transmitted in NITF format. Uncompressed national image data is stored in 2 bytes (11- and 12-bit data).
- For national systems, the term quality levels applies to the three different bit rates, plus lossless.
- In addition to image compression within national systems, there is a separate technique called pre-processing that is conducted to remap the pixel values in order to optimize the compression process. This requires the receiver to conduct a post-processing function after decompressing the image. Receivers of this data must understand the post-processing of this algorithm.

COMPRESSION STANDARDS

The following current standards are related to the aforementioned compression types:

- MIL-STD 188-161_.
- MIL-STD 188-196.
- MIL-STD 188-198A.
- MIL-STD 188-199, *Vector Quantization Decompression for the National Imagery Transmission Format Standard*.
- MIL-STD 2500C, *National Imagery Transmission Format (Version 2.1) for the National Imagery Transmission Format Standard*.
- MISP version 6.4.
- NGA Standard Identification (STDI)-0001 V1.3/CN2, *National Support Data Extension (SDE) (Version 1.3/CN2) for the National Imagery Transmission Format (NITF)*.
- NGA STDI-006, *National Imagery Transmission Format (NITF) Version 2.1 Commercial Dataset Requirements Document (NCDRD)*.

APPENDIX K
IMAGERY INTELLIGENCE APPENDIX FORMAT

The IMINT operations appendix should explain how IMINT and relevant imagery-related elements under the operational control of or supporting the MAGTF will be used to support this plan. It should also provide guidance to subordinate commanders for the conduct of IMINT operations and the support of IMINT elements and personnel identified to fulfill the IMINT requirements.

APPENDIX 7 TO ANNEX B (INTELLIGENCE) TO MAGTF OPORD XXX (U)
IMAGERY INTELLIGENCE (U)

(U) REFERENCES: Identify DOD, NGA, and other directives; combatant commander, JTF, or other higher authorities' OPORDs and TTP or SOP for intelligence and IMINT operations; pertinent maps and other geospatial information resources; and any other relevant references that pertain to anticipated IMINT operations.

1. (U) Situation

a. (U) Definition of the AO and AOI. Describe the limits of the AO and AOI. Summarize pertinent weather, terrain, and other AO's characteristics and conditions that may influence the conduct of IMINT operations.

b. (U) Enemy. Refer to annex B and current intelligence estimates for threat capabilities, limitations, vulnerabilities, and OOB pertinent to IMINT operations.

c. (U) Assigned MAGTF Organic and Supporting IMINT Assets. Identify organic and supporting forces available to perform IMINT and imagery-related functions.

d. (U) Facts and Assumptions. Derived during the mission analysis step of the MCPP.

e. (U) IMINT Considerations. List key IMINT, intelligence, or other considerations that impact this OPLAN or CONPLAN.

(1) (U) Availability of national source and commercial imagery.

(2) (U) IMINT support to and from JTF and other component headquarters.

(3) (U) Creation and manning of forward IMINT elements.

1

CLASSIFICATION

CLASSIFICATION

2. (U) Mission. State concisely the IMINT mission as it relates to the command's planned operation.

3. (U) Execution

a. (U) Concept of Operations. Reference the unit's intelligence SOP and Appendix 16 (Intelligence Operations Plan) to annex B. Restate as appropriate the commander's intent and pertinent aspects of the unit's overall CONOPS as they relate to IMINT operations. Outline the purpose and concept of IMINT operations; specify priorities; and summarize the means and agencies to be employed in planning and directing, collecting, processing and exploiting, analyzing and producing, disseminating, and using IMINT during execution of the OPORD. Address the integration of JTF, other components, theater, national, and allied forces' IMINT operations.

b. (U) Tasks for IMINT and Related Units and Organizations, Subordinate Units, and Task Force Commanders/OICs

(1) (U) Orders to Subordinate, Attached, and Supporting Units. Use separate numbered subparagraphs to list detailed instructions for each unit conducting IMINT operations, including the originating headquarters, subordinate commands, and separate intelligence support units.

(a) (U) Major subordinate commanders.

(b) (U) Commanding officer, intelligence battalion.

1 Platoon commander, IIP.

2 MTI section.

3 Staff noncommissioned officers in charge (SNCOICs), direct support teams.

4 OIC, support cell.

5 OIC, surveillance and reconnaissance cell.

6 OIC, P&A cell.

7 Others, as appropriate.

CLASSIFICATION

(c) (U) Commanding officer, VMU.

(d) (U) Commanding officer, force reconnaissance company.

(2) (U) Requests to Higher, Adjacent, and Cooperating Units. Provide separate numbered subparagraphs pertaining to each unit not organic, attached, or supporting and from which IMINT support is requested, including other components, JTF headquarters, allied or coalition forces, theater and national operational and intelligence elements.

c. (U) Coordinating Instructions. Reference Appendix 16 (Intelligence Operations Plan) and command and other pertinent forces' and organizations' intelligence and counterintelligence SOPs. Detail key changes to SOPs here or in supporting tabs. Additional topics to include or emphasize here include requesting IMINT support; direct liaison among subordinate commanders, MAGTF IMINT units, staff officers, and pertinent external organizations and agencies; and routine and time-sensitive reporting procedures and formats.

4. (U) Administration and Logistic

a. (U) Logistics. Reference Annex D (Logistics). Identify IMINT unique logistic requirements and concerns, such as any unique combat service support requirements, procedures, and other guidance to support MAGTF IMINT units and operations or procedures for specialized technical logistic support necessary from external organizations.

b. (U) Personnel. Identify intelligence unique IMINT personnel requirements and concerns.

5. (U) Command and Control

a. (U) Command Relationships. Reference Annex J (Command Relationships). Provide any instructions necessary regarding MAGTF command relationships that will influence unit IMINT operations.

b. (U) Information Management. Reference Annex U (Information Management), Annex C (Operations), and Appendix 16 (Intelligence Operations Plan). Provide any necessary instructions regarding information management (e.g., time-sensitive and routine reporting criteria, intelligence databases, reports) that will influence MAGTF IMINT operations.

c. (U) Communications and Information Systems. Reference Appendix 16 (Intelligence Operations Plan) and Annex K (Communications and Information Systems). Provide any instructions necessary regarding CIS that will influence MAGTF IMINT operations.

CLASSIFICATION

d. (U) Intelligence C2 Nodes and Facilities. Reference the unit's intelligence SOP and Appendix 16 (Intelligence Operations Plan). Provide guidance and necessary instructions regarding the establishment and operations of intelligence and IMINT C2 nodes and facilities (e.g., the surveillance and reconnaissance cell).

GLOSSARY

Section I. Acronyms

AAA ..... antiaircraft artillery
AC/S ..... assistant chief of staff
ACE ..... aviation combat element
AFP ..... all-source fusion platoon
ALT ..... altitude
AMC ..... air mission commander
AO ..... area of operations
AOI ..... area of interest
ATARS ..... advanced tactical airborne reconnaissance system
ATF ..... amphibious task force
ATO ..... air tasking order

BDA ..... battle damage assessment
BE ..... basic encyclopedia
BLS ..... beach landing site

C2 ..... command and control
CCD ..... camouflage, concealment, and deception
CCIR ..... commander's critical information requirement
CCMD ..... combatant command
CDE ..... collateral damage estimation
CDL ..... common data link
CGS ..... common ground station
CIA ..... Central Intelligence Agency
CIC ..... combat intelligence center
CIS ..... communications and information systems
CJCSI ..... Chairman of the Joint Chiefs of Staff instruction
CLS ..... contractor logistics support
cm ..... centimeter(s)
CM ..... collection manager
CM/DO ..... collection management/dissemination officer
CMD ..... command
COA ..... course of action
COC ..... combat operations center
CONOPS ..... concept of operations
CONPLAN ..... concept plan
COP ..... common operational picture
CSA ..... combat support agency
CTP ..... common tactical picture

DASC ..... direct air support center
DCGS ..... distributed common ground/surface system
DCGS-MC ..... distributed common ground/surface system-Marine Corps
DCT ..... discrete cosine transform
DIA ..... Defense Intelligence Agency
DIB ..... distributed common ground/surface system integration backbone
DIRINT ..... Director of Intelligence
DMRF ..... denominator of the map representative scale factor
DNI ..... Director of National Intelligence
DOD ..... Department of Defense
DODIPP ..... Department of Defense Intelligence Production Program
DPRF ..... denominator of the photo representative scale factor
DRO ..... departmental requirements office
DZ ..... drop zone

EEI ..... essential element of information
EID ..... entity identifier
EO ..... electro-optical
ETF ..... electronic target folder
EW ..... electronic warfare

FDCT ..... forward discrete cosine transform
FLIR ..... forward-looking infrared
FMV ..... full motion video
FOC ..... future operations cell
FoS ..... family of systems
FSCC ..... fire support coordination center
FSR ..... field service representative
ft ..... foot (feet)
FTI ..... fixed target indicator

G-1 ..... manpower or personnel staff officer
G-2 ..... intelligence staff officer
G-3 ..... operations staff officer
G-4 ..... logistics staff officer
G-5 ..... assistant chief of staff, plans
G-6 ..... command, control, communications, and computer systems staff officer
GD ..... ground distance
GDT ..... ground data terminal
GEOINT ..... geospatial intelligence
GI&S ..... geospatial information and services

HD ..... horizontal distance
HLZ ..... helicopter landing zone
HQMC ..... Headquarters, Marine Corps
HQMC-IPI ..... Headquarters, Marine Corps-Imagery & Geospatial Intelligence Branch
HUMINT ..... human intelligence

I&W ..... indications and warning
IAS ..... intelligence analysis system
IC ..... intelligence community
ICBM ..... intercontinental ballistic missile
ICR ..... intelligence collection requirement
IIP ..... imagery intelligence platoon
IMINT ..... imagery intelligence
IMR ..... imagery reference
IOC ..... intelligence operations center
IPB ..... intelligence preparation of the battlespace
IPIR ..... initial photographic interpretation report
ISC ..... intelligence support coordinator
ISR ..... intelligence, surveillance, and reconnaissance

J-2 ..... intelligence staff section
JAS ..... JSTARS antenna suite
JFC ..... joint force commander
JIOC ..... joint intelligence operations center
JISE ..... joint intelligence support element
JP ..... joint publication
JPEG ..... Joint Photographic Experts Group
JSTARS ..... Joint Surveillance Target Attack Radar System
JTAR/S ..... joint tactical air reconnaissance/surveillance
JTF ..... joint task force
JWICS ..... Joint Worldwide Intelligence Communications System

km ..... kilometers
kts ..... knots

LAN ..... local area network
LCE ..... logistics combat element
LOC ..... line of communications
LOS ..... line of sight
LP ..... landing point
LSI ..... lead systems integrator
LSRS ..... littoral surveillance radar system
LTIOV ..... latest time information is of value
LZ ..... landing zone

m ..... meter(s)
MACCS ..... Marine air command and control system
MACG ..... Marine air control group
MAGTF ..... Marine air-ground task force
MARFORRES ..... United States Marine Corps Forces Reserve
MASINT ..... measurement and signature intelligence
MAW ..... Marine aircraft wing
MC ..... MOVINT client

MCIA ..... Marine Corps Intelligence Activity
MCISR-E .....Marine Corps Intelligence, Surveillance, and Reconnaissance-Enterprise
MCO .....Marine Corps order
MCPP ..... Marine Corps Planning Process
MCRP .....Marine Corps reference publication
MARCORSYSCOM..... Marine Corps Systems Command
MCWP .....Marine Corps warfighting publication
MEF .....Marine expeditionary force
METOC .....meteorological and oceanographic
METT-T .....mission, enemy, terrain and weather, troops and support available-time available
MEU .....Marine expeditionary unit
MIDB .....modernized integrated database
MIPIR ..... multimission imagery photo interpretation report
MISP .....Motion Imagery Standards Profile
MLG..... Marine logistics group
MOJT ..... managed on-the-job training
MOS ..... military occupational specialty
MOUT..... military operations on urbanized terrain
MSC .....major subordinate command
MSN ..... mission
MTI ..... moving target indicator
MTI OS ..... moving target indicator operation suite

NATO .....North Atlantic Treaty Organization
NGA.....National Geospatial-Intelligence Agency
NIIRS ..... National Imagery Interpretability Rating Scale
NIPRNET.....Nonsecure Internet Protocol Router Network
NIST..... national intelligence support team
NITF.....national imagery transmission format
NRO .....National Reconnaissance Office
NRT .....near real time
NSA .....National Security Agency
NSG ..... National System for Geospatial Intelligence
NST ..... National Geospatial-Intelligence Agency support team

OIC..... officer in charge
OOB .....order of battle (also known as OB)
OPLAN .....operation plan
OPORD ..... operation order

P&A .....production and analysis
PD ..... photo distance
PIR .....priority intelligence requirement
POL ..... petroleum, oils, and lubricants

RECCEXREP .....reconnaissance exploitation report
RFI .....request for intelligence

RPG ..... rocket propelled grenade
RVT ..... remote video terminal

S-2 ..... intelligence staff officer
S-3 ..... operations staff officer
S-4 ..... logistics staff officer
S-6 ..... communications system officer
SALUTE ..... size, activity, location, unit, time, and equipment
SAM ..... surface-to-air missile
SAR ..... synthetic aperture radar
SARC ..... surveillance and reconnaissance center
SATCOM ..... satellite communications
SCDL ..... surveillance control data link
SIDS ..... secondary imagery dissemination system
SIGINT ..... signals intelligence
SIPRNET ..... SECRET Internet Protocol Router Network
SL ..... percent of slope
SOP ..... standing operating procedure
SRBM ..... short-range ballistic missile
SUPIR ..... supplemental photographic interpretation report

TACC ..... tactical air command center
TACTEX ..... tactical analysis and combat tracking exploitation
TCPED ..... tasking, collection, processing, exploitation, and dissemination
TDN ..... tactical data network
TEG ..... tactical exploitation group
TEG-RWS ..... tactical exploitation group-remote workstation
TEL ..... transporter-erector-launcher
TOT ..... time on target
TTP ..... tactics, techniques, and procedures

UAS ..... unmanned aircraft system
US ..... United States
UTM ..... universal transverse mercator

VADER ..... vehicle and dismount exploitation radar
VAS ..... vantage ascent software
VD ..... vertical distance
VHF ..... very high frequency
VIP-MC ..... virtual imagery processing-Marine Corps
VMFA(AW) ..... Marine fighter/attack (all weather) squadron
VMU ..... Marine unmanned aerial vehicle squadron

WAN ..... wide-area network

Section II. Definitions

airfield—An area prepared for the accommodation (including any buildings, installations, and equipment), landing, and takeoff of aircraft. See also **departure airfield**; **landing area**; **landing site**. (JP 1-02)

all-source intelligence—1. Intelligence products and/or organizations and activities that incorporate all sources of information, most frequently including human intelligence, imagery intelligence, measurement and signature intelligence, signals intelligence, and open-source data in the production of finished intelligence. 2. In intelligence collection, a phrase that indicates that in the satisfaction of intelligence requirements, all collection, processing, exploitation, and reporting systems and resources are identified for possible use and those most capable are tasked. (JP 1-02)

amphibious force—An amphibious task force and a landing force together with other forces that are trained, organized, and equipped for amphibious operations. Also called **AF**. (JP 1-02)

area of interest—That area of concern to the commander, including the area of influence, areas adjacent thereto, and extending into enemy territory. This area also includes areas occupied by enemy forces who could jeopardize the accomplishment of the mission. Also called **AOI**. (JP 1-02)

area of operations—An operational area defined by the joint force commander for land and maritime forces that should be large enough to accomplish their missions and protect their forces. Also called **AO**. (JP 1-02)

assessment—3. Analysis of the security, effectiveness, and potential of an existing or planned intelligence activity. 4. Judgment of the motives, qualifications, and characteristics of present or prospective employees or "agents." (JP 1-02) (Parts 3 and 4 of a 4-part definition.)

attach—1. The placement of units or personnel in an organization where such placement is relatively temporary. 2. The detailing of individuals to specific functions where such functions are secondary or relatively temporary. (JP 1-02)

aviation combat element—The core element of a Marine air-ground task force (MAGTF) that is task-organized to conduct aviation operations. The aviation combat element (ACE) provides all or a portion of the six functions of Marine aviation necessary to accomplish the MAGTF's mission. These functions are antiair warfare, offensive air support, assault support, electronic warfare, air reconnaissance, and control of aircraft and missiles. The ACE is usually composed of an aviation unit headquarters and various other aviation units or their detachments. It can vary in size from a small aviation detachment of specifically required aircraft to one or more Marine aircraft wings. In a joint or multinational environment, the ACE may contain other Service or multinational forces assigned or attached to the MAGTF. The ACE itself is not a formal command. Also called **ACE**. (MCRP 5-12C)

battle damage assessment—The estimate of damage composed of physical and functional damage assessment, as well as target system assessment, resulting from the application of lethal or nonlethal military force. (JP 1-02) The timely and accurate estimate of the damage resulting from the application of military force. Battle damage assessment estimates physical damage to a

particular target, functional damage to that target, and the capability of the entire target system to continue its operations. Also called **BDA**. (MCRP 5-12C)

battlespace—The environment, factors, and conditions that must be understood to successfully apply combat power, protect the force, or complete the mission. This includes the air, land, sea, space, and the included enemy and friendly forces; facilities; weather; terrain; the electromagnetic spectrum; and the information environment within the operational areas, areas of interest, and areas of influence. (MCRP 5-12C)

beach—1. The area extending from the shoreline inland to a marked change in physiographic form or material, or to the line of permanent vegetation (coastline). 2. In amphibious operations, that portion of the shoreline designated for landing of a tactical organization. (JP 1-02)

beachhead—A designated area on a hostile or potentially hostile shore that, when seized and held, ensures the continuous landing of troops and materiel, and provides maneuver space requisite for subsequent projected operations ashore. (JP 1-02)

beach width—The horizontal dimensions of the beach measured at right angles to the shoreline from the line of extreme low water inland to the landward limit of the beach (the coastline). (JP 1-02)

collection—(See JP 1-02 for core definition. Marine Corps amplification follows.) The gathering of intelligence data and information to satisfy the identified requirements. (MCRP 5-12C)

collection management—In intelligence usage, the process of converting intelligence requirements into collection requirements, establishing priorities, tasking or coordinating with appropriate collection sources or agencies, monitoring results, and retasking, as required. (JP 1-02)

collection plan—A plan for collecting information from all available sources to meet intelligence requirements and for transforming those requirements into orders and requests to appropriate agencies. (JP 1-02)

collection requirement—2. An established intelligence need, validated against the appropriate allocation of intelligence resources (as a requirement) to fulfill the essential elements of information and other intelligence needs of an intelligence consumer. (JP 1-02) (Part 2 of a 2-part definition.)

combatant commander—A commander of one of the unified or specified combatant commands established by the President. Also called **CCDR**. (JP 1-02)

command and control—(See JP1-02 for core definition. Marine Corps amplification follows.) The means by which a commander recognizes what needs to be done and sees to it that appropriate actions are taken. Command and control is one of the six warfighting functions. Also called **C2**. (MCRP 5-12C)

command element—The core element of a Marine air-ground task force (MAGTF) that is the headquarters. The command element is composed of the commander, general or executive and special staff sections, headquarters section, and requisite communications support, intelligence, and reconnaissance forces, necessary to accomplish the MAGTF's mission. The command element provides command and control, intelligence, and other support essential for effective planning and execution of operations by the other elements of the MAGTF. The command element varies in size and composition; and, in a joint or multinational environment, it may contain other Service or multinational forces assigned or attached to the MAGTF. Also called **CE**. (MCRP 5-12C)

commander's critical information requirement(s)—(See JP1-02 for core definition. Marine Corps amplification follows.) Information regarding the enemy and friendly activities and the environment identified by the commander as critical to maintaining situational awareness, planning future activities, and facilitating timely decisionmaking. The two subcategories are priority intelligence requirements and friendly force information requirements. Also called **CCIRs**. (MCRP 5-12C)

commander's intent—(See JP1-02 for core definition. Marine Corps amplification follows.) A commander's clear, concise articulation of the purpose(s) behind one or more tasks assigned to a subordinate. It is one of two parts of every mission statement which guides the exercise of initiative in the absence of instructions. (MCRP 5-12C)

contingency—A situation requiring military operations in response to natural disasters, terrorists, subversives, or as otherwise directed by appropriate authority to protect US interests. (JP 1-02)

control—1. Authority that may be less than full command exercised by a commander over part of the activities of subordinate or other organizations. 2. In mapping, charting, and photogrammetry, a collective term for a system of marks or objects on the Earth or on a map or a photograph, whose positions or elevations (or both) have been or will be determined. 3. Physical or psychological pressures exerted with the intent to assure that an agent or group will respond as directed. 4. An indicator governing the distribution and use of documents, information, or material. Such indicators are the subject of intelligence community agreement and are specifically defined in appropriate regulations. (JP 1-02)

coordination—The action necessary to ensure adequately integrated relationships between separate organizations located in the same area. Coordination may include such matters as fire support, emergency defense measures, area intelligence, and other situations in which coordination is considered necessary. (MCRP 5-12C)

counterintelligence—(See JP1-02 for core definition. Marine Corps amplification follows.) The active and passive measures intended to deny the enemy valuable information about the friendly

situation, to detect and neutralize hostile intelligence collection, and to deceive the enemy as to friendly capabilities and intentions. (MCRP 5-12C)

countermeasures—That form of military science that, by the employment of devices and/or techniques, has as its objective the impairment of the operational effectiveness of enemy activity. (JP 1-02)

current intelligence—One of two categories of descriptive intelligence that is concerned with describing the existing situation. (JP 1-02)

damage assessment—1. The determination of the effect of attacks on targets. 2. A determination of the effect of a compromise of classified information on national security. (JP 1-02)

detachment—1. A part of a unit separated from its main organization for duty elsewhere. 2. A temporary military or naval unit formed from other units or parts of units. (AAP-06)

dissemination—Conveyance of intelligence to users in a suitable form. (MCRP 5-12C)

drop zone—A specific area upon which airborne troops, equipment, or supplies are airdropped. Also called **DZ**. (JP 1-02)

essential elements of friendly information—(See JP1-02 for core definition. Marine Corps amplification follows.) Specific facts about friendly intentions, capabilities, and activities needed by adversaries to plan and execute effective operations against our forces. Also called **EEFI**. (MCRP 5-12C)

fires—(See JP1-02 for core definition. Marine Corps amplification follows.) Those means used to delay, disrupt, degrade, or destroy enemy capabilities, forces, or facilities as well as affect the enemy's will to fight. Fires is one of the six warfighting functions. (MCRP 5-12C)

force protection—(See JP1-02 for core definition. Marine Corps amplification follows.) Actions or efforts used to safeguard own centers of gravity while protecting, concealing, reducing, or eliminating friendly critical vulnerabilities. Force protection is one of the six warfighting functions. (MCRP 5-12C)

fusion—In intelligence usage, the process of examining all sources of intelligence and information to derive a complete assessment of activity. (JP 1-02)

global sourcing—A process of force provision or augmentation whereby resources may be drawn from any location/command worldwide. (MCRP 5-12C)

ground combat element—The core element of a Marine air-ground task force (MAGTF) that is task-organized to conduct ground operations. It is usually constructed around an infantry organization but can vary in size from a small ground unit of any type to one or more Marine divisions that can be independently maneuvered under the direction of the MAGTF commander. It includes appropriate ground combat and combat support forces, and in a joint or multinational environment, it may also contain other Service or multinational forces assigned or attached to the

MAGTF. The ground combat element itself is not a formal command. Also called **GCE**. (MCRP 5-12C)

helicopter landing zone—A specified ground area for landing assault helicopters to embark or disembark troops and/or cargo. A landing zone may contain one or more landing sites. Also called **HLZ**. (JP 1-02)

human intelligence—A category of intelligence derived from information collected and provided by human sources. Also called **HUMINT**. (JP 1-02)

human intelligence operations—Operations that cover a wide range of activities encompassing reconnaissance patrols, aircrew reports and debriefs, debriefing of refugees, interrogations of prisoners of war, and the conduct of counterintelligence force protection source operations. Also called **HUMINT operations**. (MCRP 5-12C)

imagery—A likeness or presentation of any natural or man-made feature or related object or activity, and the positional data acquired at the same time the likeness or representation was acquired, including: products produced by space-based national intelligence reconnaissance systems; and likeness and presentations produced by satellites, airborne platforms, unmanned aerial vehicles, or other similar means (except that such term does not include handheld or clandestine photography taken by or on behalf of human intelligence collection organizations). (JP 1-02)

imagery exploitation—The cycle of processing and printing imagery to the positive or negative state, assembly into imagery packs, identification, interpretation, mensuration, information extraction, the preparation of reports, and the dissemination of information. (JP 1-02)

imagery intelligence—The technical, geographic, and intelligence information derived through the interpretation or analysis of imagery and collateral materials. Also called **IMINT**. (JP 1-02)

imagery interpretation—1. The process of location, recognition, identification, and description of objects, activities, and terrain represented on imagery. 2. The extraction of information from photographs or other recorded images. (AAP-6)

indications—In intelligence usage, information in various degrees of evaluation, all of which bear on the intention of a potential enemy to adopt or reject a course of action. (JP 1-02)

indications and warning—Those intelligence activities intended to detect and report time-sensitive intelligence information on foreign developments that could involve a threat to the United States or allied and/or coalition military, political, or economic interests or to US citizens abroad. It includes forewarning of hostile actions or intentions against the United States, its activities, overseas forces, or allied and/or coalition nations. Also called **I&W**. (JP 1-02)

indicator—In intelligence usage, an item of information which reflects the intention or capability of an adversary to adopt or reject a course of action. (JP 1-02)

information—Unprocessed data of every description which may be used in the production of intelligence. (AAP-06)

information requirements—In intelligence usage, those items of information regarding the adversary and other relevant aspects of the operational environment that need to be collected and processed in order to meet the intelligence requirements of a commander. (JP 1-02)

infrared imagery—That imagery produced as a result of sensing electromagnetic radiations emitted or reflected from a given target surface in the infrared position of the electromagnetic spectrum (approximately 0.72 to 1,000 microns). (JP 1-02)

integration—3. In photography, a process by which the average radar picture seen on several scans of the time base may be obtained on a print, or the process by which several photographic images are combined into a single image. (JP 1-02) (Part 3 of a 3-part definition.)

intelligence—(See JP1-02 for core definition. Marine Corps amplification follows.) Knowledge about the enemy or the surrounding environment needed to support decisionmaking. Intelligence is one of the six warfighting functions. (MCRP 5-12C)

intelligence data—Data derived from assets primarily dedicated to intelligence collection such as imagery systems, electronic intercept equipment, human intelligence sources, etc. (MCRP 5-12C)

intelligence discipline—A well-defined area of intelligence planning, collection, processing, exploitation, analysis, and reporting using a specific category of technical or human resources. There are seven major disciplines: human intelligence, geospatial intelligence, measurement and signature intelligence, signals intelligence, open-source intelligence, technical intelligence, and counterintelligence. (JP 1-02)

intelligence estimate—The appraisal, expressed in writing or orally, of available intelligence relating to a specific situation or condition with a view to determining the courses of action open to the enemy or adversary and the order of probability of their adoption. (JP 1-02)

intelligence preparation of the battlespace—(See JP1-02 for core definition. Marine Corps amplification follows.)The systematic, continuous process of analyzing the threat and environment in a specific geographic area. Also called **IPB**. (MCRP 5-12C)

intelligence-related activities—Those activities outside the consolidated defense intelligence program that: respond to operational commanders' tasking for time-sensitive information on foreign entities; respond to national intelligence community tasking of systems whose primary mission is support to operating forces; train personnel for intelligence duties; provide an intelligence reserve; or are devoted to research and development of intelligence or related capabilities. (Specifically excluded are programs that are so closely integrated with a weapon system that their primary function is to provide immediate-use targeting data.) (JP 1-02)

intelligence report—A specific report of information, usually on a single item, made at any level of command in tactical operations and disseminated as rapidly as possible in keeping with the timeliness of the information. Also called **INTREP**. (JP 1-02)

intelligence reporting—The preparation and conveyance of information by any means. More commonly, the term is restricted to reports as they are prepared by the collector and as they are transmitted by the collector to the latter's headquarters and by this component of the intelligence structure to one or more intelligence-producing components. Thus, even in this limited sense, reporting embraces both collection and dissemination. The term is applied to normal and specialist intelligence reports. (JP 1-02)

intelligence requirement(s)—(See JP1-02 for core definition. Marine Corps amplification follows.) Questions about the enemy and the environment, the answers to which a commander requires to make sound decisions. Also called **IRs**. (MCRP 5-12C)

interpretation—(See JP1-02 for core definition. Marine Corps amplification follows.) A part of the production phase in the Marine Corps intelligence cycle that supports the commander's decisionmaking process. (MCRP 5-12C)

joint force—A general term applied to a force composed of significant elements, assigned or attached, of two or more Military Departments operating under a single joint force commander. (JP 1-02)

joint force commander—A general term applied to a combatant commander, subunified commander, or joint task force commander authorized to exercise combatant command (command authority) or operational control over a joint force. Also called **JFC**. (JP 1-02)

joint intelligence—Intelligence produced by elements of more than one Service of the same nation. (JP 1-02)

joint intelligence operations center—An interdependent, operational intelligence organization at the Department of Defense, combatant command, or joint task force (if established) level, that is integrated with national intelligence centers, and capable of accessing all sources of intelligence impacting military operations planning, execution, and assessment. Also called **JIOC**. (JP 1-02)

Joint Worldwide Intelligence Communications System—The sensitive, compartmented information portion of the Defense Information Systems Network. It incorporates advanced networking technologies that permit point-to-point or multipoint information exchange involving voice, text, graphics, data, and video teleconferencing. Also called **JWICS**. (JP 1-02)

landing area—1. That part of the operational area within which are conducted the landing operations of an amphibious force. It includes the beach, the approaches to the beach, the transport areas, the fire support areas, the airspace above it, and the land included in the advance inland to the initial objective. 2. (Airborne) The general area used for landing troops and materiel either by airdrop or air landing. This area includes one or more drop zones or landing strips. 3. Any specially prepared or selected surface of land, water, or deck designated or used for takeoff and landing of aircraft. See also **airfield**; **amphibious force**; **landing beach**; **landing force**. (JP 1-02)

landing beach—That portion of a shoreline usually required for the landing of a battalion landing team. However, it may also be that portion of a shoreline constituting a tactical locality (such as the shore of a bay) over which a force larger or smaller than a battalion landing team may be landed. (JP 1-02)

landing force—A Marine Corps or Army task organization formed to conduct amphibious operations. The landing force, together with the amphibious task force and other forces, constitute the amphibious force. Also called **LF**. (JP 1-02)

liaison—That contact or intercommunication maintained between elements of military forces or other agencies to ensure mutual understanding and unity of purpose and action. (JP 1-02)

logistics—(See JP1-02 for core definition. Marine Corps amplification follows.) 1. The science of planning and executing the movement and support of forces. 2. All activities required to move and sustain military forces. Logistics is one of the six warfighting functions. (MCRP 5-12C)

logistics combat element—The core element of a Marine air-ground task force (MAGTF) that is task-organized to provide the combat service support necessary to accomplish the MAGTF's mission. The logistics combat element varies in size from a small detachment to one or more Marine logistics groups. It provides supply, maintenance, transportation, general engineering, health services, and a variety of other services to the MAGTF. In a joint or multinational environment, it may also contain other Service or multinational forces assigned or attached to the MAGTF. The logistics combat element itself is not a formal command. Also called **LCE**. (MCRP 5-12C)

main effort—The designated subordinate unit whose mission at a given point in time is most critical to overall mission success. It is usually weighted with the preponderance of combat power and is directed against a center of gravity through a critical vulnerability. (MCRP 5-12C)

maneuver—The movement of forces for the purpose of gaining an advantage over the enemy. Maneuver is one of the six warfighting functions. (MCRP 5-12C)

Marine air-ground task force—The Marine Corps' principal organization for all missions across a range of military operations, composed of forces task-organized under a single commander capable of responding rapidly to a contingency anywhere in the world. The types of forces in the Marine air-ground task force (MAGTF) are functionally grouped into four core elements: a command element, an aviation combat element, a ground combat element, and a logistics combat element. The four core elements are categories of forces, not formal commands. The basic structure of the MAGTF never varies, though the number, size, and type of Marine Corps units comprising each of its four elements will always be mission dependent. The flexibility of the organizational structure allows for one or more subordinate MAGTFs to be assigned. In a joint or multinational environment, other Service or multinational forces may be assigned or attached. Also called **MAGTF**. (MCRP 5-12C)

Marine Corps Planning Process—A six-step methodology which helps organize the thought processes of the commander and staff throughout the planning and execution of military operations. It focuses on the mission and the threat and is based on the Marine Corps philosophy

of maneuver warfare. It capitalizes on the principle of unity of command and supports the establishment and maintenance of tempo. The six steps consist of problem framing, course of action development, course of action war game, course of action comparison and decision, orders development, and transition. Also called **MCPP**. *(Note: Tenets of the MCPP include top-down planning, single-battle concept, and integrated planning.)* (MCRP 5-12C)

Marine expeditionary force—The largest Marine air-ground task force (MAGTF) and the Marine Corps' principal warfighting organization, particularly for larger crises or contingencies. It is task-organized around a permanent command element and normally contains one or more Marine divisions, Marine aircraft wings, and Marine logistic groups. The Marine expeditionary force is capable of missions across the range of military operations, including amphibious assault and sustained operations ashore in any environment. It can operate from a sea base, a land base or both. In a joint or multinational environment, it may also contain other Service or multinational forces assigned or attached to the MAGTF. Also called **MEF**. (MCRP 5-12C)

Marine expeditionary unit—A Marine air-ground task force (MAGTF) that is constructed around an infantry battalion reinforced, a composite squadron reinforced, and a task-organized logistics combat element. It normally fulfills Marine Corps' forward sea-based deployment requirements. The Marine expeditionary unit provides an immediate reaction capability for crisis response and is capable of limited combat operations. In a joint or multinational environment, it may contain other Service or multinational forces assigned or attached to the MAGTF. Also called **MEU**. (MCRP 5-12C)

measurement and signature intelligence—Intelligence obtained by quantitative and qualitative analysis of data (metric, angle, spatial, wavelength, time dependence, modulation, plasma, and hydromagnetic) derived from specific technical sensors for the purpose of identifying any distinctive features associated with the emitter or sender, and to facilitate subsequent identification and/or measurement of the same. The detected feature may be either reflected or emitted. Also called **MASINT**. (JP 1-02)

multispectral imagery—The image of an object obtained simultaneously in a number of discrete spectral bands. Also called **MSI**. (JP 1-02)

National Imagery Transmission Format Standard—The suite of standards for formatting digital imagery and imagery-related products and exchanging them among members of the Intelligence Community (IC) as defined by the Executive Order 12333, and other United States Government departments and agencies. Also called **NITFS**. (MIL-STD-2500C)

national intelligence—All intelligence, regardless of the source from which derived, and including that which is gathered within or outside the United States, that pertains to more than one agency, and involves (1) threats to the United States, its people, property, or interests, (2) the development, proliferation, or use of weapons of mass destruction, or (3) any other matter bearing on US national or homeland security. (JP 1-02)

near real time—Pertaining to the timeliness of data or information which has been delayed by the time required for electronic communication and automatic data processing. This implies that there are no significant delays. Also called **NRT**. (AAP-06)

operational control—Command authority that may be exercised by commanders at any echelon at or below the level of combatant command. Operational control is inherent in combatant command (command authority) and may be delegated within the command. Operational control is the authority to perform those functions of command over subordinate forces involving organizing and employing commands and forces, assigning tasks, designating objectives, and giving authoritative direction necessary to accomplish the mission. Operational control includes authoritative direction over all aspects of military operations and joint training necessary to accomplish missions assigned to the command. Operational control should be exercised through the commanders of subordinate organizations. Normally this authority is exercised through subordinate joint force commanders and Service and/or functional component commanders. Operational control normally provides full authority to organize commands and forces and to employ those forces as the commander in operational control considers necessary to accomplish assigned missions; it does not, in and of itself, include authoritative direction for logistics or matters of administration, discipline, internal organization, or unit training. Also called **OPCON**. (JP 1-02)

order of battle—The identification, strength, command structure, and disposition of the personnel, units, and equipment of any military force. Also called **OOB**. (JP 1-02)

priority intelligence requirement—(See JP1-02 for core definition. Marine Corps amplification follows.) An intelligence requirement associated with a decision that will critically affect the overall success of the command's mission. Also called **PIR**. (MCRP 5-12C)

production management—Encompasses determining the scope, content, and format of each intelligence product; developing a plan and schedule for the development of each product; assigning priorities among the various production requirements; allocating processing, exploitation, and production resources; and integrating production efforts with intelligence collection and dissemination. (MCRP 5-12C)

radar imagery—Imagery produced by recording radar waves reflected from a given target surface. (JP 1-02)

reachback—(See JP1-02 for core definition. Marine Corps amplification follows.) The ability to exploit resources, capabilities, expertise, etc., not physically located in the theater or a joint operations area, when established. (MCRP 5-12C)

rear area—That area extending forward from a command's rear boundary to the rear of the area assigned to the command's subordinate units. This area is provided primarily for the performance of combat service support functions. (MCRP 5-12C)

security—1. Measures taken by a military unit, activity, or installation to protect itself against all acts designed to, or which may, impair its effectiveness. 2. A condition that results from the establishment and maintenance of protective measures that ensure a state of inviolability from hostile acts or influences. 3. With respect to classified matter, the condition that prevents unauthorized persons from having access to official information that is safeguarded in the interests of national security. (JP 1-02)

sensitive compartmented information—All information and materials bearing special community controls indicating restricted handling within present and future community intelligence collection programs and their end products for which community systems of compartmentation have been or will be formally established. (These controls are over and above the provisions of DOD 5200.1-R, Information Security Program Regulation.) Also called **SCI**. (JP 1-02)

sensor data—Data derived from sensors whose primary mission is surveillance or target acquisition, such as air surveillance radars, counterbattery radars, and remote ground sensors. (MCRP 5-12C)

signals intelligence—1. A category of intelligence comprising either individually or in combination all communications intelligence, electronic intelligence, and foreign instrumentation signals intelligence, however transmitted. 2. Intelligence derived from communications, electronic, and foreign instrumentation signals. Also called **SIGINT**. (JP 1-02)

situational awareness— Knowledge and understanding of the current situation that promotes timely, relevant, and accurate assessment of friendly, enemy, and other operations within the battlespace in order to facilitate decisionmaking. An informational perspective and skill that foster an ability to determine quickly the context and relevance of events that are unfolding. Also called **SA**. (MCRP 5-12C)

source—1. A person, thing, or activity from which information is obtained. 2. In clandestine activities, a person (agent), normally a foreign national, in the employ of an intelligence activity for intelligence purposes. 3. In interrogation activities, any person who furnishes information, either with or without the knowledge that the information is being used for intelligence purposes. (JP 1-02)

special operations—Operations requiring unique modes of employment, tactical techniques, equipment and training often conducted in hostile, denied, or politically sensitive environments and characterized by one or more of the following: time sensitive, clandestine, low visibility, conducted with and/or through indigenous forces, requiring regional expertise, and/or a high degree of risk. Also called **SO**. (JP 1-02)

surveillance—(See JP1-02 for core definition. Marine Corps amplification follows.) The systematic visual or aural observation of an enemy force or named area of interest or an area and the activities in it to collect intelligence required to confirm or deny adversary courses of action or identify adversary critical vulnerabilities and limitations. (MCRP 5-12C)

sustained operations ashore—The employment of Marine Corps forces on land for an extended duration. It can occur with or without sustainment from the sea. Also called **SOA**. (MCRP 5-12C)

synthetic aperture radar—A radar in which a synthetically long apparent or effective aperture is constructed by integrating multiple returns from the same ground cell, taking advantage of the Doppler effect to produce a phase history film or tape that may be optically or digitally

processed to reproduce an image. Also called **SAR** and known as **radar, synthetic aperture**. (MIL-HDBK-850)

tactical intelligence—(See JP1-02 for core definition. Marine Corps amplification follows.) Intelligence concerned primarily with the location, capabilities, and possible intentions of enemy units on the battlefield and the tactical aspects of terrain and weather within the battlespace. (MCRP 5-12C)

target—1. An entity or object considered for possible engagement or other action. 2. In intelligence usage, a country, area, installation, agency, or person against which intelligence operations are directed. 3. An area designated and numbered for future firing. 4. In gunfire support usage, an impact burst that hits the target. (JP 1-02)

target intelligence—Intelligence that portrays and locates the components of a target or target complex and indicates its vulnerability and relative importance. (JP 1-02)

technical control—The performance of specialized/professional service or the exercise of professional guidance/direction through the establishment of policies and procedures. Also called **TECHON**. (MCRP 5-12C)

validation—1. A process associated with the collection and production of intelligence that confirms that an intelligence collection or production requirement is sufficiently important to justify the dedication of intelligence resources, does not duplicate an existing requirement, and has not been previously satisfied. 3. In computer modeling and simulation, the process of determining the degree to which a model or simulation is an accurate representation of the real world from the perspective of the intended uses of the model or simulation. (JP 1-02) (Parts 1 and 3 of a 4-part definition.)

warfighting functions—The six mutually supporting military activities integrated in the conduct of all military operations. The six warfighting functions are command and control, fires, force protection, intelligence, logistics, and maneuver.

To Our Readers

Changes: Readers of this publication are encouraged to submit suggestions and changes through the Universal Need Statement (UNS) process. The UNS submission process is delineated in Marine Corps Order 3900.15_, *Marine Corps Expeditionary Force Development System*, which can be obtained from the on-line Marine Corps Publications Electronic Library:

http://www.marines.mil/News/Publications/ELECTRONICLIBRARY.aspx.

The UNS recommendation should include the following information:

- Location of change
  - Publication number and title
  - Current page number
  - Paragraph number (if applicable)
  - Line number
  - Figure or table number (if applicable)
- Nature of change
  - Addition/deletion of text
  - Proposed new text

Additional copies: If this publication is not an electronic only distribution, a printed copy may be obtained from Marine Corps Logistics Base, Albany, GA 31704-5001, by following the instructions in MCBul 5600, *Marine Corps Doctrinal Publications Status*. An electronic copy may be obtained from the United States Marine Corps Doctrine web page:

https://www.doctrine.usmc.mil.

Unless otherwise stated, whenever the masculine gender is used, both men and women are included.

CHANGES No. 2

WAR DEPARTMENT,
WASHINGTON, December 28, 1942.

FM 30–21, November 1, 1940, is changed as follows:

SECTION VII (ADDED)

GRAPHICAL REPRESENTATION OF INFORMATION

■ 57. RECORDING CHANGE.—*a.* In the G–2 section of any unit, information on enemy activity is obtained by a number of different types of studies. A means of recording changes should be used which fits both the situation and the purpose for which the information is obtained.

b. In forward positions, changes in such activities as entrenchments, obstacles, antitank fortifications, barbed wire, communications, supply installations, and dummy positions must be recorded. The most common means of recording such information is by conventional signs and symbols on maps or overlays. However, in the case of installations far to the rear or in the event of stabilization in a forward area, there are certain types of information which may best be recorded graphically.

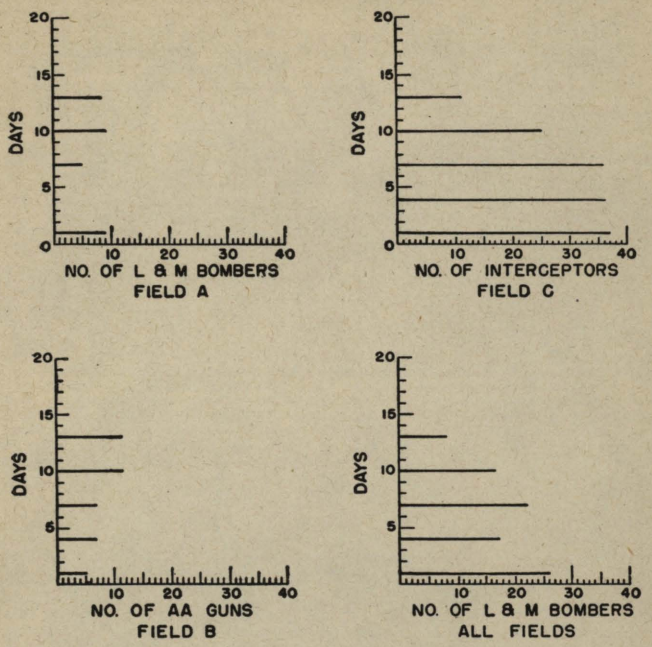
■ 58. GRAPHICAL REPRESENTATION.—Quantitative changes in enemy installations which occur over a period of time are best recorded graphically. Examples of such installations are dumps, camps, and landing fields. Graphic representation gives the degree of use of such installations, whereas indicating them on a map merely shows their presence.

■ 59. EXAMPLE.—The following is an example of the use of graphic representation: In a given theater three advance landing fields have been located and all have been photographed from 25,000 feet. The intelligence mission requires photographing

499962°—42

those fields every 3 days in order to determine enemy activity there. At the end of 13 days the following information is available from interpretation of the aerial photographs:

	Planes present			Dumps	Anti-aircraft		Vehicles	Buildings		Tents
RECORD—FIELD A										
Day	L. & M. bombers	Interceptors	Others	Present	Guns	Machine guns	Present	Under construction	Present	Present
1st	9	10	2	2	12	15	15	0	0	2
4th	0	0	2	2	12	15	12	0	0	2
7th	6	0	2	2	12	15	8	0	0	2
10th	9	10	1	2	12	15	13	0	0	2
13th	9	8	1	2	12	15	12	0	0	0
RECORD—FIELD B										
1st	0	0	1	1	4	12	3	0	1	6
4th	0	3	0	1	8	12	8	0	1	6
7th	0	9	1	1	8	12	5	0	1	6
10th	0	9	3	2	12	24	23	4	1	18
13th	0	8	2	2	12	24	17	4	1	18
RECORD—FIELD C										
1st	18	36	5	5	20	30	23	0	8	3
4th	18	35	5	5	20	30	27	0	8	0
7th	18	35	3	5	20	30	19	0	8	0
10th	9	24	0	5	12	24	14	0	7	0
13th	0	10	0	5	12	24	11	0	4	0
RECORD—ALL FIELDS										
1st	27	46	8	8	36	57	41	0	9	11
4th	18	38	7	8	40	57	47	0	9	8
7th	24	44	6	8	40	57	32	0	9	8
10th	18	43	4	9	36	63	50	4	8	20
13th	9	26	3	9	36	63	40	4	5	18



The line graphs shown above give one method of plotting graphically the information in the preceding table. Anyone interested in any particular installation or operation can tell at a glance by the length of the horizontal lines what change or progress is taking place.

BASIC FIELD MANUAL

MILITARY INTELLIGENCE

ROLE OF AERIAL PHOTOGRAPHY

(The matter contained herein supersedes TR 210–10, January 4, 1926.)

SECTION I

GENERAL

■ 1. PURPOSE.—The purpose of this manual is to prescribe the procedure for the coordination of aerial photography, to furnish a guide for the determination and interpretation of military information shown on aerial photographs, and to serve as a reference in the training of personnel in the tactical study of aerial photographs.

■ 2. SCOPE.—In addition to providing the necessary coordination between ground and air troops in the production and utilization of aerial photographs, this manual covers the fundamentals of tactical interpretation of aerial photographs to the extent needed by military intelligence personnel. The manual does not duplicate the information contained in FM 21–25 and FM 21–26 (now published as TM 2180–5). Those manuals cover the more detailed instruction needed by all map users, while this manual is confined to the coordination and tactical aspects only.

■ 3. IMPORTANCE OF PHOTOGRAPHS.—Aerial photographs are one of the most important sources of information available to a commander as well as to all echelons of command. As a source of combat intelligence they are of paramount importance to all intelligence sections, for when successfully interpreted they frequently reveal the most carefully guarded secrets in hostile territory. When properly titled, they are a

type of map showing innumerable details and later information not shown on the best topographic maps. When examined stereoscopically, they are of the greatest importance in studying the terrain. In the field of counterintelligence, they are important as a check upon the use of natural and artificial concealment and of camouflage discipline.

■ 4. VERTICAL AERIAL PHOTOGRAPHS.—*a. General.*—A vertical aerial photograph is one which is taken when the lens axis of the camera is approximately perpendicular to the earth's surface. Such photographs are very useful in making terrain studies and in gaining information of enemy activity, in the preparation and revision of maps, and, when suitably marked, as map substitutes.

b. Pinpoints.—Two or more stereoscopic vertical photographs of an isolated object or spot constitute a pinpoint. Airdromes, supply depots, dumps, road crossings, bridges, or other bottlenecks on lines of communication requiring detailed study are suitable objects for pinpoint photography. (Fig. 1.)

c. Mosaics.—An aerial mosaic is an assembly of two or more overlapping vertical photographs as described in FM 30–20. The mosaic is the most common form of photomap which will be encountered. In intelligence studies, the mosaic is especially useful in studying features that cannot be followed out completely on one photograph, such as paths, roads, railroads, etc. The principal purpose is to show an entire area in one photograph for use as a check upon new information, and to assist examining officers in comparing data on photographs with data shown on existing maps.

d. Stereo-pairs.—(1) *General.*—For details concerning stereoscopic photography and stereoscopic examination of aerial photographs see FM 21–26 (now published as TM 2180–5).

(2) *Use.*—As it is customary to make vertical aerial photographs, with an overlap, stereoscopic examination of any photographed area is possible. This should be the normal procedure in studying aerial photographs for military information. In addition to furnishing valuable information concerning the topography of a given area, stereo-pairs supply

still more valuable information concerning enemy activities. They are useful in overcoming the effect of camouflage and in locating various installations. They facilitate the detection of numerous details which could not otherwise be recognized on the ground. A stereoscopic examination makes it possible to determine in advance the effect of the terrain upon the location of defensive positions and of covered routes thereto, upon lines of supply and evacuation, upon tanks, upon observation and command posts, and upon axes of signal communication.

e. Scale.—(1) *General.*—Vertical photographs for intelligence purposes should be made of small, medium, or large scale, depending upon the purpose for which required.

(2) *Small.*—Small scale aerial photographs (1:15,000 or smaller) cover a large area but show comparatively little detail. They are of value, for they furnish considerable information concerning camps, dumps, railway activity, large demolitions such as the destruction of bridge spans 150 feet or more in length, and heavy mine craters, trench systems in open terrain, new road and rail construction, and large bodies of troops except in wooded or brush-covered country. They are also used in the preparation and revision of maps. (Figs. 12 and 50.)

(3) *Medium.*—Medium scale aerial photographs (1:10,000 to 1:15,000) show sufficient detail for ordinary intelligence and counterbattery purposes. Partly organized trench systems, airplanes on the ground, outlines of airdromes and airfields, railroad trains, columns in close formation on roads, partly concealed dumps and depots, areas upon which heavy artillery concentrations have been placed, battery positions, detail of trenches, and other field works may be seen. (Fig. 28.)

(4) *Large.*—Large scale aerial photographs (1:5,000 to 1:10,000) show great detail and are of use in distinguishing between genuine and dummy gun positions, in locating camouflage work, tank mine fields, railway cars, motorized and horse-drawn vehicles, shell holes and exploded tank mines, observation and command posts, machine gun emplacements, road barriers, demolitions of small bridges and culverts, indications of troop concentrations, such as tracks, paths,

poorly concealed equipment, pole lines carrying telegraph and telephone circuits, open wire and cable lines, bands of wire entanglements, and many other details. Large scale photographs should be limited to pinpoints. (Figs. 1 and 17.)

■ 5. OBLIQUE AERIAL PHOTOGRAPHS.—*a. General.*—Any aerial photograph which is not a true vertical is an oblique. In an oblique photograph the perspective is somewhat distorted due to the inclination of the lens, and the scale varies rapidly from the foreground to the rear. Information obtained from such photographs should always be carefully checked against a vertical photograph or map or both; otherwise the distorted perspective may cause serious errors in the location of points.

b. High oblique photographs.—A high oblique photograph is an oblique which shows the terrain up to the line of the horizon. It is very useful to the command, showing clearly the general form of the terrain and the succession of enemy organizations just as one would see them from a very high point of observation. (Fig. 2.)

c. Low oblique photographs.—Low oblique photographs, particularly those taken close to the ground, cover less terrain than high obliques but give more detail. They facilitate a correct understanding of relief, make slopes and sunken roads stand out, and reveal the breaks and gaps not visible on single vertical photographs. (Fig. 3.)

■ 6. NIGHT PHOTOGRAPHS.—Under favorable conditions, vertical photographs can be taken at night with the aid of auxiliary lighting equipment at elevations up to about 8,000 feet above the ground. Because of the fleeting nature of the light, night photographs are usually limited to single exposures, although small strip mosaics can be made. There is little difference between the detail shown on night and daylight photographs, but because the former must be taken at a comparatively low altitude one exposure necessarily covers a smaller area. (Fig. 4.)

■ 7. INFRARED PHOTOGRAPHY.—Infrared photography is taken on a special film which, while it is somewhat sensitive to most colors, is especially sensitive to infrared light. On this film,

objects register in black, white, or gray, primarily according to the amount of infrared light they reflect. Thus the relative shades of gray in which objects register on infrared film differ from the relative shades of gray in which they register on panchromatic film.

■ 8. COLOR PHOTOGRAPHY.—Color transparencies render colors in approximately their true values from altitudes of about 5,000 feet. At very low altitudes, color film requires such long exposure that motion is apparent. At altitudes in the vicinity of 10,000 feet and higher, color pictures are far too blue to be of great value. Color transparencies, except Dufay color transparencies, are slow and difficult to make and reproduce. However, because they give a grainless, easily interpreted picture and under suitable conditions render colors about as seen by the human eye, they will be used in war. Increased use may be expected as color photography is improved.

■ 9. QUICK WORK PHOTOGRAPHY.—Aerial photographs can be produced in whole or in part in the airplane by the quick work process and delivered direct to appropriate headquarters. In this type of photography no negatives are prepared, the image being recorded directly on the print itself. Normally, the photographic quality of the print will not be equal to that of a print processed in the usual manner. Neither can reproductions be made without rephotographing the picture. Quick work photography will have its greatest application during the actual progress of maneuver warfare, when time does not permit the orderly processing of films and the printing and distribution of the prints. This process makes possible the delivery of photographic information to the intelligence officer a matter of minutes only.

■ 10. SPECIALIST EXAMINERS OF AERIAL PHOTOGRAPHS.—*a.* In divisions and higher echelons of command, the intelligence section may include one or more specialists in the examination of aerial photographs. These specialists should have a thorough knowledge of the organization, marching and bivouacking characteristics, transportation, methods of combat, field fortifications, supply system, disposition of aviation units

on the ground, camouflage, and intelligence procedure of our own Army. In addition, they should have a thorough knowledge of the same things in the enemy's army. They should be patient and persevering and possess keen, observant, analytical minds.

b. The examiner should have, in proper working order, all necessary equipment and material for his work. Among essential items in all echelons should be included the enemy's or our own field fortification and camouflage regulations, maps and aerial photographs of the area, drafting equipment, stereoscope, mimeoscope, rubber cement, and files. The lower echelons will have only simple equipment.

c. The examiners should collaborate closely with intelligence personnel charged with the examination of prisoners, repatriates, and captured documents; with terrestrial and aerial observation agencies; and with sound and flash ranging troops. In this way it will frequently be possible to clarify doubtful items. As assistant intelligence officers, these specialists should be familiar with the intelligence plan and the essential elements of information of the unit to which they pertain. In the course of operations they should be kept fully informed concerning the enemy's organization, plans, activities, fortifications, and movements.

d. During the progress of operations, the specialist examiner should make a detailed study of terrain, objects, and defenses captured from the enemy. If practicable, he should be accompanied by a Signal Corps photographer for the purpose of securing close-up ground photographs of items shown on aerial photographs. In this way he perfects his knowledge of the enemy and completes a working album to assist him in his future work. Whenever possible, he should also study the appearance of identified enemy objects and works from the air.

■ 11. REFERENCES.—Field Manuals pertaining to aerial photography, mapping, and camouflage are listed in the Appendix.

SECTION II

COORDINATION OF AERIAL PHOTOGRAPHY

■ 12. RESPONSIBILITY.—*a.* The *commanding officer* of an organization to which Air Corps units are assigned or attached is responsible for the coordination of photographic missions within his own and subordinate units. He is also responsible for policies relative to the distribution of aerial photographs to all subordinate echelons within the command. In the performance of these duties he is assisted by his assistant chief of staff, G–2.

b. The assistant chief of staff, G–2 of the organization to which photographic aviation is assigned or attached, acting under the authority of the commanding officer thereof, is directly responsible for the coordination between Air Corps units and available topographic engineers, and, with due regard to the essential elements of information announced by the commander, for the coordination of photographic missions of the aviation of his own and subordinate echelons. He is also responsible for the coordination of aerial photography with the other collecting agencies and for making the necessary aerial photographs available to them.

■ 13. PHOTOGRAPHIC RECONNAISSANCE.—*a.* Aerial photographs may be made by aviation units while engaged on combat or reconnaissance missions without specific instructions from higher headquarters. Such photographs are frequently of great importance in making studies of certain activities or terrain features.

b. Photographic reconnaissance missions may be directed by higher headquarters. As far as practicable, such missions must be executed as prescribed in order that the results expected may be obtained.

c. Photography as a means of securing military information has certain definite advantages and disadvantages as compared with visual reconnaissance. It furnishes an exact and convenient document for study and a detailed, accurate, and complete record, since nothing escapes the lens of the camera. However, it is quite sensitive to atmospheric conditions and enemy antiaircraft activities, and the resulting information is delayed in reaching the user by the technical

processes incident to developing and titling the negative and making and delivering the prints. Before making requests for photographs, all responsible officers should take these considerations into account.

d. For the successful accomplishment of aerial photographic missions, it is imperative that all training emphasize the necessity for speed during the several steps in processing while maintaining a high technical quality in the finished product. The necessity of reducing to the minimum the time between exposure of the negative and the delivery of the print must be appreciated by all observation personnel.

■ 14. PHOTOGRAPHIC CAPABILITIES OF AVIATION UNITS.—*a.* The GHQ reconnaissance squadrons and army and corps observation squadrons are provided with trailer laboratory facilities. Working at maximum speed under favorable conditions, a trained photographic section is capable of the following photographic production:

Photographs	Time requisite to produce		Remarks
	From trailer laboratory	From trailer laboratory and other facilities	
Negatives	*Hours*	*Hours*	
15 (5 prints each)	2	1½	Prints partially dried; titled but not interpreted.
50 (5 prints each)	4	3	Do.
100 (5 prints each)	5	4	Do.
Prints			
1,500–2,000	24		Do.
3,000–5,000		24	Do.

b. All agencies making requests for photographs should understand these capabilities.

■ 15. REQUESTS FOR AERIAL PHOTOGRAPHS.—*a.* Requests for aerial photographs will be made through normal channels to the commander of a unit to which observation aviation is attached or assigned. They may be made in writing or

orally, but in any case must contain the following essential information:

(1) Map area or point to be photographed.

(2) Approximate hour of exposure.

(3) For oblique photograph, direction from which to be taken and elevation.

(4) For vertical photograph, the scale expressed as R. F.

(5) Purpose for which the photograph is desired.

(6) Number of prints desired and time and place of delivery.

b. Acting under the authority of the commander thereof, the assistant chief of staff, G–2, of a unit will coordinate all requests for aerial photographic missions and assign a priority to each, taking into account the essential elements of information and the needs of other sections of the general staff and of subordinate units. Requests which remain unexecuted at the end of the day will be considered in connection with later requests and assigned a new priority in conformity with their urgency.

■ 16. TITLING OF NEGATIVES.—*a. General.*—The titling of negatives is the responsibility of the Air Corps. The method employed must be uniform and must include data necessary for ready identification of the area represented, both on the map and on the ground. All prints should be made from the full negative without masks, so that every portion of the negative, including title, will show on the print.

b. Grid systems.—(1) AR 300–15 prescribes various types of grid systems applicable to military maps. All personnel concerned with the production and use of aerial photographs should be familiar with the various systems.

(2) The coordinates of the center of photographs will be indicated (*c* below). If the military grid appears on any of the maps existing for the theater, it will be used in expressing these coordinates. If the military grid is not available, the atlas grid shown on the largest scale map issued to the troops will then be substituted. If neither the military nor the atlas grid is available, a geographic grid will be improvised. For example, a point at 117°40′30″ west longitude; 50°38′00″ north latitude, should be expressed by coordinates

as: 11740W5038N, the nearest minute only being used to express the coordinates.

c. Method.—The titling of aerial photographs made for intelligence purposes in the theater of operations and in all tactical exercises will be in letters and numerals ⅛ inch in height along the black strip at the bottom, reading from left to right, as follows (figs. 6 and 7):

(1) An arrow ½ inch in length in lower left-hand corner of the negative indicating north, with letter N superimposed over center of the shaft.

(2) Name of locality or nearest locality.

(3) Approximate coordinates of the center of the photograph.

(4) Scale of the photograph expressed as representative fraction, in case of a vertical; altitude above the ground in feet and focal length of camera, in case of an oblique.

(5) Hour.

(6) Date arranged in the following order: day, in figures; month, in letters; and year, in figures.

(7) Designation of squadron.

(8) Serial number of the negative.

d. Reconnaissance strips.—The first photographs of a reconnaissance strip will be titled as prescribed in *c* above. The other photographs of the strip will only be numbered serially.

■ 17. EXECUTION OF PHOTOGRAPHIC MISSIONS.—*a. General.*—The commander of a designated observation squadron executes photographic missions in accordance with the priority and conditions specified on the approved request of the headquarters to which assigned or attached.

b. Preparation of photographs.—Upon the successful completion of a photographic mission, the negatives are developed and titled without delay, and a minimum of from 5 to 22 prints, except those made exclusively for mapping purposes, are prepared in accordance with the instructions of G–2.

c. Distribution of photographs.—One print is retained by the observation squadron, and the remaining prints and the negatives are sent to the G–2 of the unit to which the squadron pertains. The intelligence liaison officer from the corps

or army, if present, studies the retained print for information of immediate importance, which, if found, is transmitted to the G–2 of the higher unit by the most rapid means of communication available.

■ 18. ACTION OF G–2 UPON RECEIPT OF PHOTOGRAPHS.—*a. Redistribution.*—Upon the receipt of aerial photographs from the observation squadron, G–2 will ordinarily redistribute them as follows:

	Number of copies
Commander of next higher unit	1
Retained by G–2 of unit	2
Unit topographic company or battalion	1
Unit air officer	1
Unit artillery officer	1
Commander of subordinate unit requesting photograph [1]	([2])

[1] To be redistributed as directed by the commander concerned.
[2] Remaining copies (ordinarily not more than 15).

b. Final study for determination of military information.—One copy of each aerial photograph retained by G–2 should be studied in great detail, including stereoscopic examination if stereo-pairs are available, and in connection with other photographs of the same area and items of information made available by other collecting agencies, with a view of determining all possible military information shown on the photograph. The study should be coordinated with the specialized studies of other copies of the photograph made by the artillery intelligence section and the Air Corps intelligence service. Only when interpretation has been definitely made will items of information be reported as facts. All doubtful items will be referred to other collection agencies for verification. All items definitely determined will be disseminated by G–2 and considered by him in the preparation of estimates of the enemy capabilities and intentions. After this copy of the photograph has otherwise served its purpose, the area shown on the photograph and its serial number and date are entered on a graphic index map (fig. 5), and the photograph is then filed according to the area for future reference. The index of the 1:20,000 map will be the filing index. Each print will be filed in folders according to its coordinates, each folder to cover the area of one of the 1:20,000 map sheets.

c. Study to determine value as a map.—While the first copy of the aerial photograph retained by G–2 is being studied for military information, the second copy should be evaluated for its possible use by subordinate echelons of command as a map or as a supplement to existing maps. Based upon this study, G–2 will issue instructions to the appropriate topographic company or battalion for its reproduction by lithography or contact printing by the multiple rapid printer when available, and for its distribution to subordinate units. Each photograph will frequently be useful to subordinate units down to and including the infantry platoon and tank section. As many as 400 copies of such lithographs or contact prints may be required, and these must receive early distribution to be of maximum value. When this copy has otherwise served its purpose, it should be turned over to the officer charged with examination of enemy personnel, repatriates, and captured documents for possible use in connection with his work.

d. G–2 report.—In order that all elements of command may be informed of available photographs, a list of successful photographic missions will be included in each G–2 report.

■ 19. ACTION OF TOPOGRAPHIC ENGINEERS.—*a. Determination of topographic data.*—The copy of each aerial photograph furnished the topographic company or battalion should be studied in connection with the best available map, photomap, or mosaic with a view of determining topographic data that may be of value in any future revision of the map, photomap, or mosaic. When this study is completed, the print is filed for future reference in the same manner as prescribed in paragraph 18*b*.

b. Distribution of lithographs or contact prints.—From the negatives of each photograph furnished by G–2, the topographic company or battalion completes and distributes in the manner prescribed in FM 30–20 lithographs or contact prints of each aerial photograph as directed by the commanding officer.

■ 20. FILING OF NEGATIVES.—G–2 of the corps or army will maintain a file of negatives of aerial photographs. If requests are made for additional photographs, the topographic

company or battalion will be directed to reproduce as contact prints or as lithographs the necessary copies. Negatives will be retained by G–2 as long as required, ordinarily not longer than 3 months, and then sent to a central record section to be designated by the theater commander, where they will be filed for final disposition upon the termination of hostilities.

SECTION III

USE TO BE MADE OF AERIAL PHOTOGRAPHS

■ 21. GENERAL.—There are many uses for aerial photographs in modern warfare. They are of value not only in determining information of the enemy and the terrain but also in the preparation and execution of all types of operations. This section deals only with some of their more important uses as intelligence documents.

■ 22. AS A MAP.—*a.* Maps are graphic representations of the terrain; aerial photographs are detailed representations of the terrain as it appears at a particular time. Therefore, when properly titled, vertical photographs should be considered as maps, even though the exact scale is not known and some distortion of detail may exist. If taken shortly before the time of use they are extremely important as supplements to maps, showing all details at the time of exposure.

b. High oblique photographs taken in the direction of march are especially convenient and valuable as road maps. They are also of great value in the preparation of operation maps. However, there is a certain amount of danger involved in the use of the oblique as a map because of the distortion of scale and the false perception of increased elevation in the background of such a photograph.

■ 23. IN PREPARATION OF OBJECTIVE FOLDERS.—Aerial photographs of fixed installations, towns, bottlenecks on lines of communication, and important terrain features are extremely significant in air operations and should be included in objective folders whenever available. (Fig. 1.) They are also of great assistance in planning and executing mechanized operations.

■ 24. IN ENGINEERING PLANNING.—*a.* In planning the engineering work which will be required in territory held by the enemy, but over which an advance is planned, study of aerial photographs of the area is essential. The amount of destruction, actual or to be expected, can be estimated, width of structures or streams computed, amount of materials estimated, mine fields located, conditions of roads determined, location of engineering supplies revealed, and much other preliminary planning work completed, prior to occupation of the terrain.

b. Aerial photographs may be of great value in planning demolitions, particularly for demolitions over a large area. The photographs have greatest value in making detailed studies of demolitions in defiles and on river lines and in planning antitank mine fields. Since demolitions on a large scale are normally planned for terrain which is to be released to the enemy, photographs may frequently be secured at a larger scale than can be expected of terrain held by the enemy. In making the demolition plan, the study of these aerial photographs should supplement personal reconnaissance and assure that no important structures or works at critical points are overlooked. When time for personal reconnaissance is not available, aerial photographs are of maximum value and if of sufficiently large scale may reveal sufficient data on which to plan the demolition.

■ 25. IN PLANNING FOR ATTACK UPON FORTIFICATIONS.—Detailed information concerning defensive arrangements, areas that cannot be covered by the defender's fire, and camouflage, especially on lines of communication necessary for the attack of a fortification or fortified position, may be gained from a study of aerial photographs. Results of these studies should be confirmed by terrain studies and reconnaissance in force, if this is necessary. Based upon this information, the composition of the troops as well as the necessary equipment and material and the special training measures to insure the successful execution of the attack can be determined. (Fig. 8.)

■ 26. IN DETERMINING INFORMATION OF ENEMY.—*a.* If systematically exploited as a direct source and as a check upon

other sources, aerial photographs will disclose information about the enemy that can be obtained by no other means. Information derived from all sources should be coordinated and items from the various collecting agencies checked against each other and studied under the direction of the G–2 of the unit concerned. Latest aerial photographs should be compared with earlier ones to determine the most recent work or activities of the enemy.

b. An aerial mosaic of the area traversed by a prisoner of war or repatriated national is frequently of great value in the examination of such personnel. Based upon information which he furnishes, the route traversed by a prisoner prior to his capture is marked on a mosaic. The prisoner is then questioned concerning doubtful items shown on pinpoints along the route. In this way, much information is acquired concerning objects which otherwise cannot be identified. Information furnished by a prisoner or repatriate should be checked against items which are already known or verified by rephotographing and restudying the object. The accuracy of a prisoner's or repatriate's statements concerning items that have been definitely verified will establish the degree of credence to accord him.

c. Captured documents frequently constitute an excellent means of identifying objects on aerial photographs especially if made on the same date. Sketches should be carefully examined for notations of machine guns, mortars, fake works, and other items which can be checked by use of aerial photographs.

d. Appropriate artillery intelligence sections will study aerial photographs to determine enemy artillery activities and the location of bottlenecks on lines of communication, railheads, dumps, observation and command posts, and bivouac or assembly areas. The work of the artillery intelligence sections of subordinate echelons is reviewed and their findings compared with and incorporated in those of the artillery section of the higher unit. In this manner the enemy artillery situation on the front of the division, corps, army, and the entire front is established and kept up to date.

■ 27. By Artillery.—Aerial photographs are of particular value to the artillery in the determination of targets and the

effect of fire. (Figs. 9 and 10.) In the absence of an accurate map, they are indispensable as a means of planning fire support and of controlling unobserved fire. They are very useful in the reconnaissance and selection of positions and of routes thereto; by the use of suitable aerial photographs many artillery survey operations may be avoided. They are valuable in testing the effectiveness of artillery camouflage and are a means of verifying the reports of other information gathering agencies such as observation battalions.

■ 28. IN LANDING OPERATIONS.—*a.* Aerial photographs of beaches and the adjacent terrain made prior to a landing will prove of greatest value. (Fig. 11.) In good weather both natural and man-made obstructions to landing operations can be located from photographs. The nature of the beach, whether steeply shelving or gently shelving, which is very important to a landing force commander in his decision as to the feasibility of landing on a certain beach, can also be determined. A very accurate estimate of wave heights can also be made from a study of stereoscopic pairs. Color transparencies are especially valuable in studies of the beaches and frequently reveal the unobstructed channels and the nature of the bottom.

b. Photographs taken during and after landing, if completed by the quick work process, will prove of the greatest value in determining the enemy reaction and the progress of our own troops. They should be delivered to the troops ashore as well as to the higher command afloat.

■ 29. IN RIVER CROSSINGS.—In planning a river crossing, aerial photographs should be made of those reaches of the river for which crossings are contemplated. These photographs, particularly when examined stereoscopically, will facilitate the selection of ferrying points and bridge sites for the various crossings. They may reveal conditions existing on both sides of the river, the character of the river banks, the river bed, the location of underwater obstructions, both natural and man-made, the defensive arrangements of the enemy, and the location of shoal spots or rapids in the river. Cover for preliminary concentration of material may also be located by study of aerial photographs. (Fig. 12.)

■ 30. IN COUNTERINTELLIGENCE.—*a.* Aerial photographs of areas or positions occupied by our own troops furnish the very best evidence of success or failure of counterintelligence measures adopted for the protection of troops on the ground. Faulty camouflage work, breaches of camouflage discipline, and failure to utilize natural cover may be detected easily on photographs. (Figs. 13 and 14.) Photographs are also valuable in planning dummy works, installations, and airdromes and in checking their deceptive worth.

b. Photographs are of great importance to the engineers charged with the development of measures for the protective coloration and camouflage of individual and organizational equipment and matériel.

SECTION IV

IDENTIFICATION OF OBJECTS FROM AERIAL PHOTOGRAPHS

■ 31. GENERAL.—Man is accustomed to viewing objects horizontally or, if looking down from a height, obliquely. A vertical aerial photograph portrays military objects in an unfamiliar aspect. Objects which form regular lines, in general, are easy to identify on aerial photographs, but difficulties are encountered in identifying concealed or small objects which present no contrast of shade with surrounding objects, and in identifying deliberately concealed military features. The solution of these difficulties requires special knowledge, training, and experience.

■ 32. PURPOSE.—The purpose of identification is to determine the objects shown on an aerial photograph and to discover obscure or hidden features through related visible ones.

■ 33. BASIS OF IDENTIFICATION.—*a. General.*—To identify objects shown on aerial photographs, the examiner relies in general on familiarity with the characteristic appearance of certain objects on aerial photographs, shadows, texture, differences as compared with former photographs, and information from other intelligence sources.

b. Characteristic appearance.—Through experience gained in working with aerial photographs and by frequent flights

in the air, the interpreter should acquire a knowledge of the appearance of objects as viewed from above.

c. Light and shade.—(1) *General.*—Objects on aerial photographs are generally identified by a study of light and shadows. If not correctly understood, shadows will give a reversed impression, causing elevations to appear as depressions and depressions as elevations. *Vertical aerial photographs should be held so that the shadows fall toward the examiner.* In an oblique aerial photograph, shadows play no part. If observed in the direction of exposure, they will give a clear impression of what has been photographed.

(2) *Shadows and form.*—Shadows will show the shape of an object which is perhaps otherwise unrecognizable on a vertical photograph.

(3) *Shadows and size.*—The shadows cast by different objects will be in direct proportion to their height. The approximate size of objects may, therefore, be determined by comparing their shadows with those of objects of known height. This should be done with caution because of the effect of slope of ground upon length of shadow.

(4) *Shadows and relief.*—While gentle slopes usually cannot be distinguished on vertical aerial photographs, the crests of sharper slopes as a rule may be identified by the difference in light reflected by the two slopes. Ravines and the deeper depressions are indicated by the darker coloring of such areas. Hills may also be indicated by their shadows.

(5) *Shadows and camouflage.*—Shadows will reveal camouflage which otherwise might be invisible. Fake shadows which are sometimes employed in camouflage work should be easily identified on aerial photographs.

d. Texture.—The arrangement of the constituent parts of a material is known as "texture." A change in this arrangement has a direct effect upon the reflection or absorption of light and therefore upon photograph negatives. As footprints, trails, tracks, spoil, works, and sometimes camouflage itself cause a change in the texture of the earth's surface or the vegetation thereon, they will be revealed on aerial photographs and will establish a record of many activities in a given area.

e. Confirmation.—Information gleaned from aerial photographs should be confirmed by evidence from other collecting agencies whenever possible. Liaison between the specialist examiner of aerial photographs and assistant intelligence officers specializing in other fields should facilitate this work.

■ 34. METHOD OF EXAMINATION.—*a. General.*—Aerial photographs should be examined systematically and objectively. The examiner should concentrate on each detail of a photograph. He should avoid jumping at conclusions, but should bear in mind every possible identification of any particular detail. After considering the various probabilities, he should determine whether or not there is sufficient evidence to justify a definite decision. Photographs taken on a single mission may give little definite information, but if considered with other photographs, intelligence summaries, and statements of prisoners, much valuable positive or negative information may be obtained.

b. Procedure.—(1) *Preliminary examination.*—The preliminary examination begins with the orientation and location on the best available map of the area shown on the photograph. Conspicuous terrain features, such as stream lines, railways, highways, and villages, are oriented with the map. The photograph is first examined with the naked eyes. After this is completed, a detailed examination of the picture is made with a magnifying glass and with a stereoscope, if stereo-pairs are available, to determine information that might have been overlooked.

(2) *Comparison of old and new photographs.*—A comparison of old and new photographs of the same area will reveal changes which have been made in the intervening period. On arriving in a new area, it is advantageous to photograph the terrain to show its exact condition at the time of arrival. Later this will facilitate the gathering of information in the area. Upon relief, a unit should turn over its file of photographs to the relieving unit.

(3) *Study of area as a whole.*—The defensive organization of an area is generally based upon a plan which coordinates all defensive arrangements. Information derived from a study of an aerial mosaic of the area, supplemented by information from other sources, frequently makes it possible

to determine, at least partially, the enemy's plan of defense. The study is facilitated by low oblique photographs.

(4) *Study of details.*—Details are studied on vertical photographs and stereo-pairs, supplemented at times by oblique photographs. The actual examination of stereo-pairs should be made in a good light with the aid of a magnifying glass and a stereoscope. The examiner should study each object in detail, covering the whole photograph in a methodical manner. He should suspect all regular forms, as there are few geometrical figures or straight lines in nature. *He must try to establish facts and in doing so should confine himself to military essentials.* The examiner should be thoroughly familiar with the terrain and all available enemy information in the area under consideration. He should compare the photographs with a map of the area, for this will enable him to avoid serious errors.

(5) *Annotation.*—Aerial photographs should not be marked or annotated until they have been thoroughly examined and then only in such a way as not to obliterate detail. Objects should be indicated on the photograph without obliterating essential detail. A distinction should be made between objects actually identified and those located from prisoners' statements or otherwise. If markings are made on the photograph, the ordinary conventional signs should be used. The names of topographic features, such as villages, trenches, roads, and map coordinates, should rarely be shown on photographs. (Fig. 15.)

(6) *Report.*—The final report is made by noting the results of the study on the photograph by means of a sketch, or by sketching the items on tracing paper pasted to the aerial photograph. A complete report must answer the questions: What, where, and when?

SECTION V

IDENTIFICATION OF ENEMY ACTIVITIES FROM AERIAL PHOTOGRAPHS

■ 35. GENERAL.—*a.* Military operations have a profound effect upon the terrain of the area involved, depending, of course, upon their intensity and the size of the forces engaged.

These activities make marks upon the terrain which are reproduced on aerial photographs and thus become a source of valuable military information.

b. The methods used in studying enemy activities are similar to those employed in ordinary aerial photograph reading except that greater attention is paid to minute details, for the smallest detail on an aerial photograph taken during active operations may be of great importance.

■ 36. CAMOUFLAGE.—The enemy will try to make objects deceptive or invisible to the eye and camera, but generally it is not possible to accomplish both at the same time. Camouflage invisible to the eye is occasionally visible to the camera, and vice versa. Color effects are generally used to camouflage from the eye. To camouflage from the camera, nets may be used to break up shadows, and tracks and blast marks may be covered up or concealed by confining them to locations near roads or hedges or inside buildings where they cannot be seen. Spoil may be covered up, scattered, or disguised. Breaches of camouflage discipline tend to defeat the best efforts at concealment by means of artificial cover. Ordinary camouflage is more visible after a snowfall. With a white background a different type of camouflage is required. For more complete information see FM 5–20. (Figs. 14 and 16.)

■ 37. ROADS, TRACKS, AND PATHS.—*a.* Roads, tracks, and paths are among the most revealing features of enemy activities found on aerial photographs. Dead-end trails and roads are of especial significance. An abrupt ending usually means that some activity such as a dump, an observation post, or a machine-gun emplacement is near the end of the trail or path. Development and deployment for action will show up clearly in maneuver warfare in all but close terrain. In defensive operations, tracks and paths will disclose the enemy's activities in great detail, frequently furnishing the clue to the location of many defensive installations. The main communication trenches will generally be indicated by paths parallel to them, which are made by carrying parties at night. Trenches in bad condition are also frequently indicated by parallel paths. On quiet parts of the front the appearance of new tracks or the gradual disappearance of

tracks will frequently give positive or negative information of the enemy's activites in a locality. During artillery preparation, new tracks near dugouts under bombardment are sure signs that the dugouts have not been destroyed or that they have been reoccupied. Tanks and other mechanized weapons moving into assembly positions make unmistakable tracks. (Figs. 17, 20, 22, 23, and 25.)

b. The presence of troops may be disclosed by the cutting of new paths, trails, or roads, by fire or smoke, and by a general lightening of the appearance of the area. The presence of vehicles may be disclosed by the disruption of the road shoulder at the point at which they left the road, and the crushing of the vegetation incident to their movement into concealed positions which show very plainly in night as well as in day photographs. Troops deploying for action leave unmistakable trails and tracks as they fan out from march columns. Marching troops are easily detected on main roads but are more difficult to detect if they use the shoulders. Dust arising from dirt roads will reveal troop movements even in heavily wooded areas. (Fig. 25.)

■ 38. TYPES OF WORKS.—*a.* The works, installations, and tactical dispositions employed by various armies in different situations will vary in details of shape, appearance, and relative locations. The types of works used by the enemy must be carefully studied, especially those on ground recently captured. G–2's of higher echelons should keep an album of interpreted aerial photographs for use in studying new photographs.

b. The illustrations in this manual are largely from the World War and exemplify what was accomplished at that time with available means under the conditions of position warfare.

■ 39. TRENCHES.—*a.* Trenches are readily distinguished by their traversed or zigzag trace revealed by the shadow of trench walls or by spoil. Shadows indicate the depth; shallow, dummy, or incomplete trenches cast little shadow. The conspicuousness of spoil depends upon the type of soil and the newness of the work, chalky or light-colored spoil being very difficult to conceal. Recent work is generally indicated

by a different appearance than surrounding soil. Any unusual amount of spoil should be scrutinized carefully, as it may indicate subterranean work. When a trench system has been heavily shelled, the previous contrasts rapidly disappear, and the study of photographs becomes increasingly difficult. Trenches in use are generally more distinct in outline than those not being used because they are kept in condition, but aerial photographs can seldom be relied upon to indicate whether or not they are occupied. (Figs. 26 to 29, incl.)

b. Fire trenches usually have straight firing bays separated by variously shaped traverses, while communicating trenches generally zigzag.

c. Trenches can be analyzed in snow pictures, due to the contrast of the shadows against the white background. If the trenches are occupied, the repeated trackings of the men may show, and dummy trenches are easily identified from real trenches. (Fig. 30.)

■ 40. BREASTWORKS.—Breastworks are usually constructed in city streets or in marshy or swampy terrain where trenches would quickly fill with water. They may be identified by their regular trace and characteristic shadows.

■ 41. ORGANIZED SHELL HOLES.—*a.* Shell holes are frequently organized for defense. They may be prepared and organized prior to an offensive or consolidated quickly during a battle.

b. When systematically organized, shell holes will generally be in pairs, constructed in well-drained ground, and connected by underground passages leading to a common dugout. The sides of shell holes may be revetted and the tops roofed and camouflaged. Such shell holes are not difficult to find on large scale photographs, and may be distinguished from ordinary shell holes by their more definite outline, the spoil dumped in the vicinity, tracks, and the entrance to the dugout.

c. Makeshift shell hole systems are more difficult to detect, but may be distinguished from ordinary shell holes by their darker appearance if they have been deepened. Occupied shell holes are generally found on patches of dry ground, which should be scrutinized carefully. Tracks are by far the surest indication of occupancy.

■ 42. WIRE.—*a.* Broad wire entanglements show on photographs as a band or line varying from light to gray to almost black, depending upon the age of the entanglement and its contrast with the color and texture of the adjacent ground and vegetation. New wire is more difficult to detect than old wire, as grass and other vegetation growing in old areas give them a distinctive, darker appearance. The study of photographs to locate wire should include not only the trench system but also fortified shell holes, battery positions, villages, hedges, and ditches. (Figs. 27 to 29, incl.)

b. As ground is cut up by bombardment, wire becomes increasingly difficult to identify. It should not be concluded that no wire exists because there are no signs of it on a vertical photograph. An oblique photograph may reveal wire not visible on a vertical photograph. (Fig. 29.)

c. The presence of wire may be betrayed by the tracks of working parties on either side of it, or by paths which suddenly change direction in passing through the entanglement.

d. As wire appears as a black band in snow, it is then visible when not otherwise apparent. It is rarely possible to discover wire entanglements in woods. (Fig. 30.)

■ 43. DUGOUTS.—The first indication of a dugout is usually the spoil thrown up during its construction. Earlier photographs of a defensive system should be compared with more recent ones in order to discover fresh spoil, which should be carefully noted, as the actual location of the dugout may be concealed by scattering the spoil. Frequently the first indication of a new defensive position is the appearance of a line of dugouts. The position of these dugouts should be carefully plotted, as they may be so camouflaged as to be no longer visible in photographs taken after the trench has been completed. The size of dugouts may sometimes be estimated by the amount of spoil. Occupied dugouts are sometimes revealed by the melting of snow from the heat of the fires inside.

■ 44. MACHINE GUNS.—*a. General.*—Machine guns are so difficult to locate on photographs that as a rule they can be detected only by knowing where to look for them. Aerial

photographs should be used mainly to corroborate reports from front-line troops and information from other sources.

b. Mobile situations.—Because machine-gun emplacements are simple in type and utilize all available natural cover, it is extremely difficult to identify them in mobile situations. In the attack, machine guns are generally placed on high ground where they can furnish support by overhead fire or grouped in batteries on a reverse slope about 1,500 yards in rear of the front line. In the defense, they will be found in positions with a good field of fire and covering approaches, such as ravines, bridges, etc., or flanking the edges of woods or elevations. High ground is usually defended by guns posted on the flanks of the elevation instead of on the crest. Ground which offers the best positions for flanking strong points should be carefully studied, for machine guns are often posted about 1,000 yards from the defenses which they protect by flanking fire. Sometimes they are indicated by the absence of wire and grass in the field of fire. When a machine gun location is suspected—

(1) Look carefully for tracks between the position and the roads or paths.

(2) As a machine gun is rarely employed alone, look for indications of adjacent machine-gun positions.

(3) Draw an arc with the position as the center to determine the probable field of fire.

(4) Note if the field of fire of the machine gun covers the terrain effectively; if it does not, look for a probable new position.

c. Position warfare.—In position warfare, machine guns are generally located close to the trenches, so they can deliver cross fire along the front of wire belts or cover the flanks and rear of fortified areas. Open emplacements in a trench can usually be recognized by the firing platform cut into the parapet, and covered emplacements by the V-shaped embrasure. They may be found—

(1) Where an angle occurs in the trace.

(2) Within easy reach of a communication trench.

(3) At the end of a path in front of a trench.

(4) Outside the trench system where a small forward sap leads to an emplacement protected by a semicircle of wire or in excavations behind the front line.

(5) In wire or on higher ground behind first-line trenches.

■ 45. 37-MM GUNS OR SIMILAR WEAPONS.—In searching for the positions of 37-mm guns or similar weapons, the examiner should understand the characteristics of the weapon and then proceed in the same manner as outlined for machine guns.

■ 46. LISTENING, OBSERVATION, AND COMMAND POSTS.—*a. Listening posts.*—Listening posts appear on aerial photographs as small excavations either under the first belt of wire or just behind it. Their positions are generally disclosed by tracks and saps leading to them. Detached listening posts are frequently constructed in no man's land. They may be camouflaged, encircled by wire, and provided with a covered approach. If the contour of the ground permits, listening posts may also be used as machine-gun positions. (Fig. 31.)

b. Observation posts.—(1) Observation posts are usually carefully camouflaged. They should be looked for on commanding ground in the vicinity of deep shelter or in or near such objects as a group of trees, hedges, or structures. They are often near the end of a dead-end path and should be suspected whenever a trail or path ends.

(2) An observation post is indicated by tracks or paths, telephone lines, and in organized ground by small trenches leading off from the main system.

c. Command posts.—Command posts will generally be located in buildings, in protected positions on reverse slopes, and in sheltered woods. They will usually be revealed by the trails, paths, or telephone lines which converge upon them. Panels for communication with friendly aviation will frequently reveal the location of command posts. (Fig. 32.)

■ 47. ANTITANK OBSTACLES AND ROAD BLOCKS.—*a.* In an organized position, antitank obstacles may consist of ditches, wire rolls, concrete pillars connected by steel cables, concrete blocks, railroad rails embedded in the ground or in concrete, wooden piling, or rubble masonry. An antitank mine field, consisting of a broad band of contact mines either buried or laid checkerwise on the surface of terrain suitable for the movement of

tanks or mechanized vehicles, constitutes an effective obstacle. Such mine fields may be detected by spoil, paths, or vehicle tracks parallel to the front.

b. In mobile situations, tank traps, and road blocks will usually be found along roads, generally at defiles or at crossroads. In order to hold the vehicle under fire a barrier is built consisting of a ditch, a covered or uncovered crater with vertical sides, or a heavy obstacle. Antitank mines will normally be found in or flanking the exposed sides of the barrier. Crossroads, defiles, causeways, bridges, deep road cuts, and side hill road cuts, as well as adjacent fields, should be examined for these articles. (Fig. 33.)

■ 48. MINE SHAFTS.—Mine shafts are difficult to distinguish on an aerial photograph, because great care is usually taken to conceal the spoil, which is often carried some distance by light railways. Proper interpretation can best be made by experts who are familiar with the mining technique. The results of mining operations can be checked by means of aerial photographs. (Fig. 34.)

■ 49. CONCRETE FORTIFICATIONS.—As concrete fortifications are located with a view of avoiding observation, or are provided with artificial concealment, they are often difficult to identify until the whole area has been cleared by heavy shell fire. After intense bombardment they appear on a photograph as geometrical figures standing above the level of the ground, having in most cases survived the prevailing destruction due to their superior powers of resistance. Concrete fortifications under construction are often disclosed by the whiteness of the concrete and the appearance of the ground where the concrete was mixed, by tracks of vehicles, or by narrow gage lines which transported the material (Fig. 35.)

■ 50. LOCATION OF BATTERIES.—*a. Natural cover.*—The enemy will take every precaution to conceal battery emplacements, utilizing villages, hedges, ditches, orchards, woods, thickets, ravines, and sunken roads for the purpose. Positions in the open may be dug in. They are usually provided with camouflage. Emplacements in ravines and sunken roads are frequently dug in and so well hidden that they are difficult to

locate, as the roads, being used for other purposes, will not show any signs of extra activity near the batteries. The primary considerations in the location of batteries are to provide concealment and cover for men and guns. Unless the batteries are in or near a village where the personnel can be housed in adjacent buildings or cellars, each battery will usually have dugouts and ammunition dumps close to the gun positions. During an advance or withdrawal, however, battery positions will generally afford no protection either for the personnel or for the guns, although locations near a road or some natural feature of the ground may give some protection. For each battery position a number of dummy or alternate emplacements are usually constructed. (Fig. 36.)

b. Artificial cover.—Natural cover will be supplemented by camouflage designed to furnish the maximum protection from both ground and aerial observation. Positions in the open will be camouflaged if time permits. Alternate and dummy positions will be constructed for purposes of deception. (Fig. 37.) Antiaircraft artillery is difficult to camouflage from aerial view. Patches in woods which appear lighter or darker than their surroundings may indicate the location of artillery positions. Such areas should be carefully studied for additional indications, such as trails and paths.

c. Evidence of battery positions.—(1) Batteries are usually spotted on photographs by tracks leading to them, by increased traffic on nearby roads and trails, by faulty camouflage, by piles of ammunition, and by latrines, dugouts, bivouacs, and kitchens. Sometimes horse lines or vehicles can be seen. Guns are only a part of the evidence of the existence of a battery. Batteries concealed by overhead cover may be detected by trails or narrow gage railroads leading to them, or by the tracks of the gun crew. Even if the battery emplacement is hidden, it is difficult to conceal the activity in its vicinity. Blast marks made by the guns tend to defeat camouflage, showing up as white scores where the surface has been blown away by the discharge and as black smudges on snow. During dry weather, blast marks may be visible for some time after the position has been vacated, and so are

no proof that an emplacement is occupied, but rather that a position has been active—a distinction which is liable to be overlooked. A photograph revealing blast marks when snow is on the ground usually indicates an active emplacement but may be only a well-prepared dummy. (Figs. 38 to 40, incl.)

(2) Guns hidden by camouflage or protected by overhead cover and firing through embrasures may be detected by the shadow of the camouflage or by blast marks. Dummy batteries can usually be distinguished by the exaggerated blast marks and tracks of too regular a pattern. The stereoscope is essential in studying such positions.

(3) Batteries in the woods are revealed by slashings, by white marks on the ground due to construction of emplacements or to traffic around guns or shelters, and by trails, narrow gage railroads, and wire lines leading to battery positions.

(4) Antiaircraft guns are generally grouped by batteries of three or four guns in regular pattern. (Fig. 14.)

d. Study of our battery positions.—Examiners should study photographs of our own battery positions taken during both peace and war, so that they may be familiar with the appearance of batteries in different situations.

■ 51. STUDY OF EFFECT OF OUR OWN ARTILLERY FIRE.—Aerial photographs may be used in adjusting artillery fire and in studying its effects. Photographs taken for these purposes should be developed by quick work methods and made available at the earliest practicable moment. (Figs. 41 and 42.)

■ 52. BURIED CABLES AND OVERHEAD TELEGRAPH AND TELEPHONE LINES.—*a. Buried cables.*—Open cable trenches can usually be distinguished on photographs by their fairly straight course and construction, and by their irregular outline when filled in. They should be marked on a map when first discovered, as they are difficult to find after being established for some time. Cable trenches aid in discovering command posts, headquarters, telephone exchanges, camouflaged batteries, observation posts, and other important centers.

b. Overhead lines.—Overhead lines appear as regularly spaced white dots, these being the displaced earth where the

poles have been erected. These dots are connected by a thin white track made by the men walking from pole to pole when putting up the wire. Overhead lines in a cultivated field will frequently stand out clearly as small dark spots because the soil around the posts has not been disturbed. Overhead lines can be determined on clear photographs if the shadows thrown by the poles can be seen. In melting snow the overhead lines may appear as evenly spaced black dots.

c. Ground lines.—Advancing troops lay ground lines as they progress. These always lead from one important communications center to another. The repair of these lines caused by frequent breaks goes on constantly and results in the making of telltale tracks or paths.

■ 53. REAR INSTALLATIONS.—*a. General.*—Military operations require large concentrations of troops, ammunition, and supplies; the construction of airdromes and hospitals; the preparation of railheads, detraining points, and other facilities. All of these are generally revealed by aerial photographs. A study of the area in rear of the enemy's front lines is, therefore, highly important.

b. Reserves.—(1) Local reserves are held in concealed positions close to the front. Evidences of their presence which may be found on aerial photographs are huts or other temporary shelters, numerous paths and tracks, picket lines and motor or gun parks, watering places, and kitchens.

(2) General reserves are usually held well back from the front or in training camps still farther to the rear. Large billets, extensive training facilities, and considerable activity are evidences of their presence. (Fig. 43.)

c. Supply and ammunition dumps.—Depots and dumps are points of supply for front-line units. Their location depends upon the accessibility of railroads and highways. Points where various means of communication join should be carefully examined. If open storage is used, dumps can usually be identified by the regular segregation of the various types of property. Forward supply points are usually more carefully concealed or camouflaged than those in the rear. Because of the increased range and importance of aviation, it will be necessary to camouflage all supply installations. They may be detected on aerial photographs by signs of activity

in their vicinity. Supply points become smaller toward the front. Signs of unusual traffic at certain points will indicate the location of forward dumps even when concealed. Abandoned dumps will soon show lack of use. (Figs. 44 and 45.)

d. Detraining points.—Military activity at detraining points is difficult to conceal during daylight hours and may even be detected at night. Aerial photographs will frequently reveal not only the detrainment but also the composition of the forces detrained. They are also of value as a check on the results of aerial bombardment. (Figs. 46 and 47.)

e. Hospitals.—Hospitals are generally located on railroads or other lines of communication at points where there is no ammunition. They are usually identified by the Red Cross sign but in the forward areas may be concealed or camouflaged. (Fig. 44.)

f. Landing fields and airdromes.—(1) Enemy aviation will probably be widely scattered throughout his rear. On the ground the airplanes will be concealed by camouflage or natural cover and may be provided with overhead protection.

(2) Enemy airdromes and landing fields may be indicated by hangars; by landing devices, such as tees, smoke contrivances, lights, and wind vanes; by especially prepared landing areas and distinctive accessory buildings which are difficult to camouflage or conceal. (Figs. 48 to 50, incl.)

(3) Permanent airdromes may be built underground, and the landing fields may be concealed by natural planting supplemented by camouflage.

g. Balloon beds.—Captive balloons behind the enemy's front lines are extremely difficult to conceal except when deflated.

SECTION VI

INTERPRETATION

■ 54. GENERAL.—Information derived from aerial photographs and all other evaluated information will be given consideration by G–2 in the preparation of his conclusions relative to the enemy's capabilities. The procedure followed is outlined in FM 30–5.

■ 55. EVIDENCE OF ENEMY'S INTENTIONS AS REVEALED BY AERIAL PHOTOGRAPHS.—*a. General.*—The general attitude of the

enemy, whether offensive or defensive, can usually be ascertained by a study of aerial photographs in connection with information from other sources. The kind and degree of completion of enemy works, the number and location of dumps, and the amount and location of reserves, if shown on aerial photographs, will furnish evidence of the offensive or defensive plans of the enemy. Aerial photographs will be of greatest utility in these studies during periods of stabilization. In maneuver warfare it will be difficult to distinguish between offensive and defensive preparations.

b. Offensive preparations.—(1) *General.*—Offensive preparations by the enemy usually leave unmistakable marks upon the terrain, which, if properly interpreted in connection with information from other sources, furnish the commander advance notice of the enemy's intentions. Among the indications of an impending attack may be an increase in artillery and antiaircraft artillery battery positions, and a general forward displacement of mechanized units, artillery, reserves, airdromes, and supplies, and dumps of bridge material near a river. New or improved roads, deviations from existing roads, new or extended railroad lines, and a general increase in both road and railroad traffic may also be observed.

(2) *Position warfare.*—New and improved communication trenches, new and unusual trails, saps pushed in advance of the front line and linked up to form jumping-off trenches, new and improved dugouts and assembly trenches, new trench mortar emplacements, such as shell holes connected by trenches, new practice trenches, sometimes modeled after our own, and new gas projection emplacements may furnish indications of an attack.

c. Defensive preparations.—Defensive preparations are indicated by tank barriers or obstructions, by traverses and dugouts marking an intended new line, by strengthening and deepening of trenches, by additions to existing wire, by new switch trenches, and by an increase in battery positions especially toward the rear. After a defensive position has been well-defined, it will be studied for the distribution of defending troops, for details of organization, and for the probable routes by which reserves can be engaged. The study should include both front and rear, and should anticipate the en-

trance into line of division reserves and even of reinforcing divisions for sustained counterattacks. Therefore, all shelters, camps, roads, observation stations, and battery emplacements in the rear zone will be given the closest attention.

■ 56. INTERPRETATION DURING OUR OWN OFFENSIVE OPERATIONS.—*a.* In position warfare, interpretation during our own offensive operations falls into three distinct phases:

(1) Preparatory.

(2) Destruction of enemy's works.

(3) During and after an attack.

b. Preparatory.—The purpose of studying aerial photographs in conjunction with maps in preparation for offensive operations is to give the various elements of command detailed information concerning critical terrain features and bottlenecks on the enemy's lines of communications and the disposition of his troops on the ground and their defensive organization. Evaluated photographs are used by all elements as supplements to the designated maps. They are of particular importance to the Air Corps, parachute troops, air infantry, and mechanized troops and in operations incident to landing on a hostile shore or a river crossing.

c. Destruction of enemy's works.—(1) The aerial photograph is of real value in studying the destruction of enemy works. It shows the effect of our artillery and aerial bombardment and can be studied and compared with older photographs of the same area, thus facilitating the evaluation of operations in preparation for an attack. Three degrees of destruction should be considered: Destroyed, seriously affected, and only slightly affected. A field work should be considered destroyed when its offensive value has been reduced to a condition equivalent to that of connecting shell holes. It has been seriously affected when it can only partially fulfill the function for which it was intended. It is only slightly affected when it is still able to fulfill its defensive role.

(2) The degree of destruction of enemy works may be shown by marking each hit on the photograph. An overlay is then prepared showing in different colors the areas corresponding to the three classes of destruction indicated above.

These overlays should also show any works reconstructed or maintained by the enemy in spite of the bombardment. Such overlays should be prepared at the close of the day or at designated hours.

d. During and after attack.—(1) *During battle.*—Aerial photographs taken during battle may reveal among other things the—

(*a*) Position of attacker.
(*b*) Location of hitherto unknown defenses.
(*c*) Preparations for withdrawal or counterattack.
(*d*) Movement of reserves and their destination.
(*e*) New targets for our artillery.

(2) *After battle.*—After battle, aerial photographs may give the most accurate information concerning the situation, revealing among other things the organization and the connection of shell holes to form trenches, the construction of temporary dugouts, the location of obstacles, and the movement of reserves for counterattack. They are of greatest value in determining whether or not trenches or their remains are occupied by the enemy. The only sure indication of activity is the presence of trails for supply and relief. Aerial photographs taken during and after battle should be carefully studied for indications of new command posts, location of reserves, supply arrangements, communications, and new locations of machine guns and artillery.

this investigation, intelligence analysis was defined as a spectrum of analytical judgmental activities involved in the processing and production of intelligence, where particular individuals may devote more or less time to different aspects of such activities according to their individual roles in the intelligence cycle.

The IMINT production model described in this report was developed to serve as a basis for selecting IMINT processes involving high analytical and judgmental content for further study, directed at understanding the cognitive functions that underlie these IMINT processes. Thus, the model was constructed with a specialized focus, for the purposes of the study described above. Rather than concentrating exclusively on either strategic or tactical IMINT, the model was designed to encompass both dimensions of IMINT. The rationale for this decision was the fact that imagery interpretation analysts (IIAs) with more than minimum length of service are likely to operate in each type of mission at some time in their career, demonstrating the practical assumption that the required knowledge base and cognitive skills are similar for the two dimensions of IMINT. The imagery interpretation analyst is the true generic focus of the IMINT production model presented in this report; in order to gather data for developing the model 56 interviews with IIAs were carried out at 8 sites, including both strategic and tactical missions.

The report contains three sections: an introduction, an overview of the IMINT production model, and the model description. Section 1 describes the IMINT model in the context of the study discussed above, and also treats the scope of the model and the collection of the information on which the model is based. Section 2 presents an overview of the model, describing findings about the role of the imagery interpretation analyst, the impact of management on analysis, the IMINT time dimension, and the special role of informal information channels in IMINT analysis. This section also describes the format of the model description, which is represented in terms of hierarchical input-process-output (HIPO) charts. Section 3 presents the model, which is segmented into two major parts: IMINT production management activities and IMINT processing, analysis, and reporting activities.

ARI Research Reports and Technical Reports are intended for sponsors of R&D tasks and for other research and military agencies. Any findings ready for implementation at the time of publication are presented in the last part of the Brief. Upon completion of a major phase of the task, formal recommendations for official action normally are conveyed to appropriate military agencies by briefing or Disposition Form.

FOREWORD

Intelligence collection systems have proliferated over the past several years, increasing in complexity and in volume of output. However, there has been no corresponding improvement in the ability of intelligence personnel to analyze this flood of data. US Army Intelligence and Security Command (INSCOM) studies and Army Research Institute (ARI) research indicate that improved support to and training of analysts are necessary to effectively utilize the increased collection capability and satisfy increasing demands for intelligence within current personnel constraints. INSCOM and ARI therefore initiated a joint research program to provide improved support to the intelligence analyst. During early discussions of the issues it became clear that any procedural, training, organizational, or system changes to support analysis will be effective only if based upon a detailed understanding of the analysts' role, methods and thought processes in intelligence production. The first need was to evaluate and describe the human analytic processes underlying intelligence analysis, synthesis and production. The present paper, one of several products of this initial effort, provides a production model of imagery intelligence which focuses on the human processes and factors involved.

The methodological approach used to study current imagery intelligence production involved interviews with image interpretation personnel in different organizations with varying levels of experience, familiar with either tactical or strategic operations, as well as observation of operations during field exercises. Imagery intelligence documentation

and research reports obtained from INSCOM and ARI as well as analyst files also provided data and background material as a basis for the imagery production model. Invaluable and outstanding support was received by the research team from personnel at numerous imagery interpretation training or production facilities.

The research was accomplished by a government-contractor team under contract MDA 903-78-C-2044 and monitored jointly by INSCOM and ARI. Continuous interaction and collaboration of personnel from Operating Systems, Inc., INSCOM and ARI insured a multidisciplinary approach to this research.

This report and a corresponding model of signals intelligence production previously developed by INSCOM provide a basis for the development of a detailed functional model of the intelligence analyst. The current report should be very useful during the development or evaluation of training materials, procedures, doctrine and automated support for the image interpreter analyst.

IMAGERY INTELLIGENCE (IMINT) PRODUCTION MODEL

BRIEF

Requirement:

To develop a model of the processes involved in the production of imagery based intelligence. This model will be used to support subsequent research on the cognitive functions of both single mode (e.g., signals intelligence; imagery intelligence) and multi-source intelligence analysts.

Approach:

A series of structured interviews was conducted with image interpretation personnel in a variety of organizations. An attempt was to include persons with various levels of experience, familiar with tactical or strategic operations. Interviews with developers of training materials, and observation of classroom instruction and of field exercises, provided additional information on individual and group responsibilities. The interviews and observation were supplemented by documentation and research reports from INSCOM and ARI. The various findings and viewpoints were consolidated and integrated into a model of the processes being examined.

Product:

The model of imagery intelligence production processes is presented as a series of hierarchical input-process-output (HIPO) charts with parallel verbal discussion of critical points. This format, discussed in detail in the text, provides a convenient means for representing the complex processes involved at a usable level of detail. The model is divided into two major parts: activities associated with production management; and activities associated with processing, analysis, and reporting.

Utilization:

The model presented lays an important foundation for a continuing effort to describe in detail the cognitive processes involved in intelligence analysis and to develop training and system support to analysts. The model will be useful during the development or evaluation of training materials, procedures, doctrine of employment, and automated support for the image interpreter.

1.0 INTRODUCTION

1.1 Background

The Imagery Intelligence (IMINT) Production Model has been developed as part of a study entitled 'Investigation of Methodologies and Techniques for Intelligence Analysis' aimed at constructing a model of the cognitive processes underlying intelligence analysis. There are three basic assumptions motivating this research. First, it is assumed that there exists a set of common analytical processes which crosscut the various intelligence disciplines, constituting the core processes of intelligence analysis. Second, it is assumed that the set of core processes represents a continuum of analytical complexity ranging from those lower in cognitive and judgmental content to those involving a high degree of cognition and judgment. Third, it is postulated that a better understanding of these core analytical processes will

- facilitate efforts to develop and evaluate training programs and training doctrine for intelligence analysts;
- provide criteria for the development and evaluation of advanced system designs in support of intelligence analysis,
- provide assistance in personnel selection, motivation, and career planning;
- provide criteria for evaluating intelligence analysis processes, and for modifying and adapting such processes;
- contribute to the improvement of intelligence analysis management and formulation of operating policies and procedures.

The approach to identifying the set of core analytical processes and developing a generic cognitive model based on these is to investigate analytical processing as currently practiced in two types of single source analysis, subsequently generalizing to all source analysis. The initial task thus involved a preliminary investigation of signal intelligence (SIGINT) to isolate those SIGINT processes which appeared to have a high analytical and judgmental content for further study directed at an understanding of the cognitive processes that underlie them. The basis for the initial investigation was the SIGINT production model prepared by the Kuras-Alterman Corporation [Ref. 29].

The second intelligence discipline investigated under this study was imagery intelligence (IMINT). Since no comparable production model existed for IMINT, the model described in this document was prepared to serve as a basis for selecting IMINT processes involving high analytical and judgmental content, and to compare these with similar SIGINT processes in order to provide an initial definition of the core analytical processes that crosscut the various intelligence disciplines.

This initial definition of core analytical processes and the cognitive processes underlying them based on SIGINT and IMINT analytical processing will then be expanded to all source analytical processing, including HUMINT. A generic cognitive model for intelligence analysis will then be developed, which will demonstrate the nature of, and relationships between, specific cognitive components used in intelligence analysis activities. Such components operate within the head of the analyst and include, among others, memory, perceptual, conceptual, decision, and learning aspects.

When completed, the generic model will highlight the commonalities and differences among various intelligence analysis disciplines, and will provide a systematic, meaningful framework which will prove useful in a number of ways. The design of tasks and tasking procedures, training regimens, and task-supportive technologies can benefit from a systematic framework for the comparative description of intelligence analysis specialties formulated in terms of cognitive functioning. Areas of analytic practice may be identified for which unrealistic demands are now made on various aspects of an analyst's cognitive resources. Components of emergent new analytic tasks may present themselves, and the model may suggest better ways to process them. A comparative framework such as the model can provide a systematic, rationalized means for the borrowing of insights and techniques by different specialties from one another. The generic model can provide a common ground to promote better understanding, coordination, and orchestration between the efforts of different specialties. For each of the possibilities just mentioned, the model may operate to suggest research questions and research approaches for the solution of problems.

As indicated earlier, to insure that the generic cognitive model is representative of a range of intelligence, it will be based on several kinds of information. Specifically:

(1) A model of processing activities for SIGINT production [Ref.29];

(2) A model of processing activities for IMINT production;

(3) A range of interview and observational data involving SIGINT, IMINT, and HUMINT.

This document presents the IMINT production model. IMINT interview and observational data outside the scope of this model will be treated in a later paper.

1.2 Scope of the IMINT Production Model

The IMINT production model presented in this report was developed with a specialized emphasis and focus, to serve the specific needs of the research study described in the preceding paragraphs. The model should not be construed as having detailed applicability for other purposes, although it may provide useful insights outside the original intent of the study. In its main outlines, the model represents a framework

within which the common aspects of various IMINT specialties are described. It is neither an exhaustive nor a detailed description of any particular IMINT specialty, although some of the dimensions of variation among specialties are noted.

1.2.1 Strategic versus Tactical IMINT. A major issue in developing the model of IMINT production involved the decision to use IMINT processing as practiced on the tactical level as a basis for the model, or IMINT processing as performed by the national strategic resources, or to construct a model that would represent both tactical and strategic IMINT. The last alternative was selected for two reasons. First, an imagery interpretation analyst (IIA) who has a career of any length is likely to serve at some time on both levels, indicating that the analytical and cognitive processing is at least presumed to be similar; this makes it important to accommodate both processing environments within the same IMINT production model, in order to accomplish the objectives of the basic study described in Section 1.1. Second, preliminary investigation of IMINT indicated apparent parallels between IMINT processing on the strategic and tactical levels. With the exception of a few real time imagery interpretation tasks that are exclusive to the tactical mission -- i.e., Side-Looking Airborne Radar (SLAR), and Infrared (IR) processing -- there are obvious parallels in almost all aspects of IMINT production (including imagery media, IMINT analysis, collateral resources, time phasing, and products). The main differences between the strategic and tactical processing environments involve the percentage of time devoted to various IMINT analytical and information handling activities (reflecting differences in mission requirements), support availability, and the range in skill levels and knowledge of individual IIAs working in the mission (Army strategic II facilities, for example, apparently do not utilize the lower skill levels).

1.2.2 Format of the Model. The detailed processing steps in different IMINT specialties, and between the same activities performed at the tactical and the strategic levels vary as to both inclusion and sequence within the activities and processes, making a detailed flow charting form of representation inappropriate. The parallels between specialties, and between tactical and strategic level IMINT processing emerge more clearly at a less detailed level of description, and are consequently best illustrated by hierarchical input-process-output (HIPO) charts. The representation conventions for these charts are explained in Section 2. Thus, unlike the SIGINT production model [Ref.29], the IMINT model does not consist of step-by-step flow diagrams of detailed task activities.

1.3 Data Collection

The sources of information on which the IMINT production model is based include the documents listed in the references (INSCOM and ARI reports, Army training manuals and field manuals), site visits to the strategic and tactical II facilities listed in Appendix A, and numerous detailed interviews with IIAs at all levels.

The majority of available documentation in the II field addresses training of lower skill level tactical analysts and the more mechanical aspects of the IMINT production process. There exists no formal documentation describing IMINT production in the national strategic environment.

The more complex aspects of IMINT analysis -- especially those aspects which are relevant to development of a generic cognitive model of intelligence analysis -- are passed on as an 'oral tradition', or are spontaneously learned by an IIA. The high security classification of many IMINT products is a major contributing factor in sustaining this 'oral tradition' and restricting the availability of reference documents and other materials, such as training imagery and II keys, in the tactical environment. Interviews with IIAs were thus the most important source of information for the model.

2.0 IMINT PRODUCTION MODEL OVERVIEW

B. IMAGERY INTELLIGENCE PRODUCTION MODEL

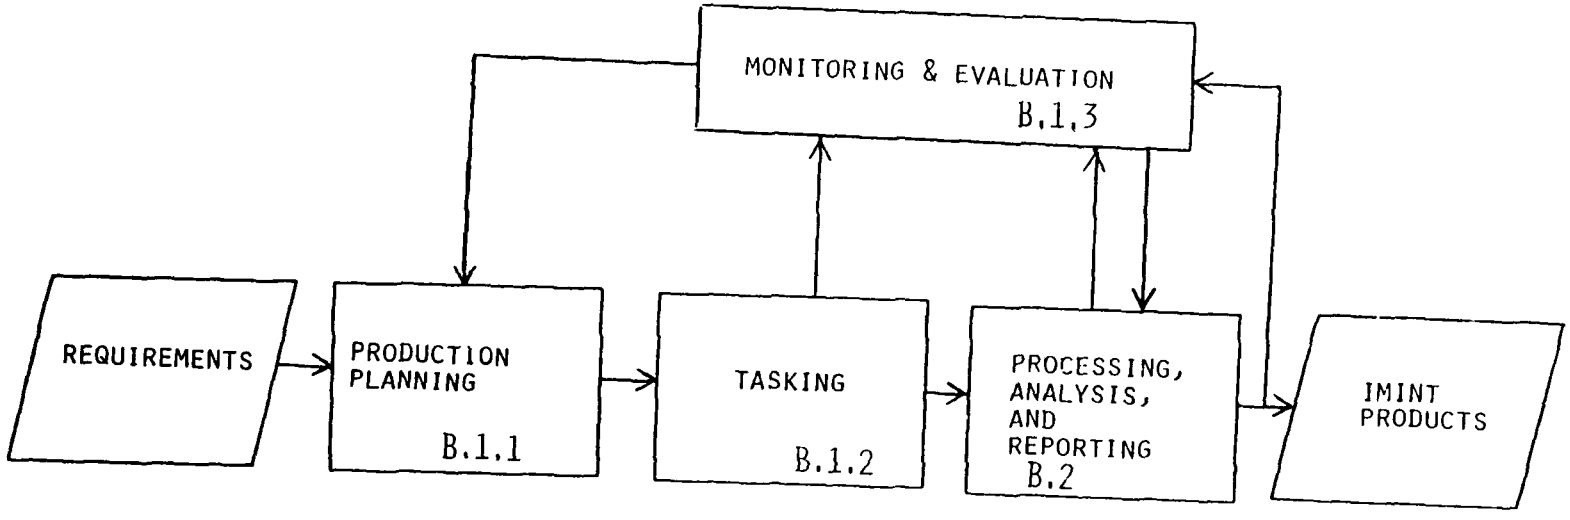

Figure 2-1. Model Overview

2.1 Concept of IMINT Production

The IMINT production process involves a combination of management, analytical, and support activities that operate against defined requirements and generate specified products. In attempting to determine the analytical and cognitive processing that occurs during imagery interpretation, it became clear that the management functions of planning, tasking, and evaluation had major impacts on the performance of imagery interpretation activities, and on the role of the image interpretation analyst (Section 2.1.1). As shown in the overview chart of the IMINT production model, Figure 2-1, these management activities are included as an integral component. Each of the management activities is discussed in the model description (Section B.1), although the amount of detail is less than for the analytical activities (Section B.2), which are the focus of the model development. Management of the II facility, which also affects the performance of IMINT activities, is discussed in Section 2.1.2, while the important impacting factor of timeliness is treated in Section 2.1.3. The formal lines of communication in the model overview chart show the use of feedback mechanisms through monitoring of tasking, analytical processing, and products. Feedback is one of the most ubiquitous and powerful mechanisms that occurs in the IMINT context, and is thus addressed throughout the IMINT production model. In addition to these formal lines of communication, and perhaps more effective, are the informal lines of communication described in Section 2.1.4.

2.1.1 The Role of the Image Interpretation Analyst (IIA). The obvious focus of the study of IMINT production was the role of the imagery interpretation analyst (IIA). No documentation describes how the IIA actually derives intelligence information from imagery. As noted above, the training manuals and relevant reports listed in the references concentrate on what IIAs do -- on the mechanical, observable activities -- rather than on how they do it. Thus much of the information on which the IMINT production model is based is derived from interviews with practicing IIAs or IIA instructors. These interviews allowed the construction of a role model for the IIA which is quite different from the image conveyed by the documents listed in the references.

Imagery interpretation is a highly skilled profession with areas of specialization. As in any intelligence field, the IIA must adapt rapidly to the changing world situation, as well as to evolving imagery collection capabilities and changes in tasking.

In performing imagery interpretation tasks, IIAs bring to bear the cumulation of their professional skills, experience, and knowledge in attempting to derive a product that will satisfy the needs of the user community within the constraints of available time and resources. IMINT analysts have a challenging task; their perception of threat is often the ultimate basis for critical strategic and tactical decision making.

Far from 'bean counting', the IMINT analytical activity involves complex processes of deductive reasoning. IIAs do not simply look at objects: they must be concerned with the associations between a given object and other objects which are not visible, between visible objects and configurations (e.g., TO&Es) indicating organizational size and strength, between objects and their function, and therefore, the degree of threat indicated by a given piece of equipment in a particular state of readiness, or by a particular activity in process. A strategic level IMINT instructor teaches his students the 'LST' principle, which he sums up in the following terms:

- L - Look at all the imagery.
- S - See what is in the optical field of view. Discovery and recognition of a target must come from within you. It is a function of background knowledge and concentration.
- T - Think about what you see. Combine logic, knowledge, curiosity, and most important, imagination, in the search. Only at the thinking level can one be considered an analyst.*

The issue of background knowledge is an important one. IIAs prepare for the IMINT production activities not only by practicing the mechanical skills of IMINT production, but also by developing a background in geographic, cultural, and technical aspects associated with the area of responsibility. They must be familiar with the geography and cultural background of an area in order to distinguish unusual objects and conditions from normality. IIAs in general are highly concerned with pursuing available information resources, both background and collateral. They are information entrepreneurs and archivists, whose external memory store of information is as important as the internal one it supports.

Successful IIAs appear to be highly motivated, and have a natural or developed curiosity about the area of analysis, frequently comparing themselves to 'detectives'. IIAs tend to be highly individualistic in their methods and take pride in their accomplishments; however, this individualism is balanced by a strong 'team' sentiment. IIAs feel responsible for assisting other members of an II group in the education of novice IIAs and in carrying out complex tasks.

2.1.2 Management of an II Production Facility. II facilities exhibit considerable difference in production processing based on their mission and resources in terms of staff, support, and imagery collection inputs. The activities of the II facility as a whole may vary considerably as a function of time depending on the active missions the facility has at the time of observation. A tactical unit in garrison may have only a training and exercise mission.

Facilities with active missions have problems in allocating scarce personnel and support resources to perform tasks. Facilities without active missions are faced with the problem of preparing for contingency operations and maintaining the proficiency of the IIA staff. In the latter cases, the dedication of the II facility management and senior analysts is the determining factor in how actively the facility engages

*From the instructional materials of John Schlegel.

in training and preparation for contingency operations of various types.

A case in point which was referred to frequently by interviewed analysts was that, especially in peacetime, Army corps level II operations tended to assume division II functions. This condition occurs because most decisions are made at corps level, where intelligence operations have ready access to national assets and direct knowledge of the broader context of intelligence operations. Division level intelligence resources thus tend not to be regularly tasked except for major exercises (such as Reforger), and must rely on their own initiative to maintain an active proficiency in imagery interpretation.

Support capabilities can also constrain the activity of the II facility. Lack of storage for classified material, secure communication channels, and photo lab facilities has a major impact on the II facility capacity for performing active missions.

A given facility may not engage in a complete spectrum of imagery interpretation tasks, because of area of responsibility, constrained resources, and/or lack of support capabilities. The II facility management can provide training or exercises to complement its active mission role, to diversify its capabilities, and satisfy general training requirements for the II MOS skill area.

2.1.5 Timeliness in IMINT Analysis and Reporting. The intelligence products which derive from imagery analysis may support a diversity of missions, including Indications and Warning (I&W), targeting, collection exploitation, basic intelligence, or direct support. The scope and form of these products vary substantially between tactical and strategic missions. An attribute of these missions and products that is common for both strategic and tactical imagery interpretation is timeliness. In IMINT production, timeliness requirements are defined in terms of First Phase, Second Phase, and Third Phase processing. Definition of IMINT processing in terms of three phases is a convention which is normally applied only in the environment of the national strategic IMINT resources. For purposes of this model, the three phased definition is also applied to tactical level processing because of the parallelism which exists in terms of analytical and reporting time constraints. The effect of these phases on analytical and reporting activities is described in detail in Section 6.2 of the model; the following paragraphs present brief definitions of the approximate time periods represented by these phases.

First Phase processing refers to derivation of intelligence from the initial scan of imagery (or from real time imagery generated by SLAR, IR, or video devices) and is normally tasked by time-critical applications.

Second Phase processing refers to exploitation of imagery within a period of more than one and less than 24 hours, and applies primarily to current intelligence applications.

Third Phase processing includes periodic reporting, special support-processing wih 48-hour or longer turnaround, and basic intelligence reporting.

While organizations within a national strategic IMINT facility may specialize in only one phase of processing, a tactical II facility more commonly engages in all three phases of IMINT production, depending on operational requirements.

2.1.4 Informal Information Channels. One of the more powerful mechanisms that operates to make the IMINT production process more efficient and adaptive to the environment is the informal information flow and coordination that takes place during the course of imagery interpretation production. As with other intelligence analysis disciplines, imagery interpretation is an inexact process because results can be partially speculative, data are incomplete, ambiguities are prevalent, and the environment being monitored is continually changing. Informal communications channels allow the IMINT production process to exploit all available information sources in the generation of useful intelligence products.

Informal information flow tends to be more direct because it bypasses chain of command delays and avoids the overhead of filling out forms and having paperwork reviewed. Personal contact or secure voice conversations are the most common communications channels for informal information flow, but secure TTY circuits (OPSCOMM, INDICOM) are also used.

Informal communication channels do not conflict with standard operating policies or formal reporting policies, but in fact act as a supplement. Experienced II analysts are allowed to initiate external communications without management approval when the context is within the given IIA's area of responsibility. Imagery interpretation is the type of process which cannot be monitored at the process level. Management would have to replicate the IIA's entire task in order to determine if the analyst was performing that task correctly. II management must depend on the professionalism of the II analyst to seek informal help from other IIAs in problem areas. Direct control of the II analyst is generally achieved only by monitoring the IIA's time, productivity, and quality of the products he generates, as well as by tasking the IIA in areas where his proficiency is known.

The major types of informal information flow that were identified through interviews with II analysts and instructors are shown in Figure 2-2. Actual flow is more in terms of a network, where analysts in the network are tied together by mutual area of interest. Creation of these networks is also an informal process resulting from joint working groups, personal references, appearance of analyst names on intelligence products, and past experiences in dealing with other agencies. The informal networks seem to be sustained on the basis of credibility of the analyst's information and sharing of information resources that are either not globally available or are more easily understood when interpreted by a specialist in the area.

Two types of informal communications most often mentioned by interviewed analysts as having positive effects on the quality of IMINT products were:

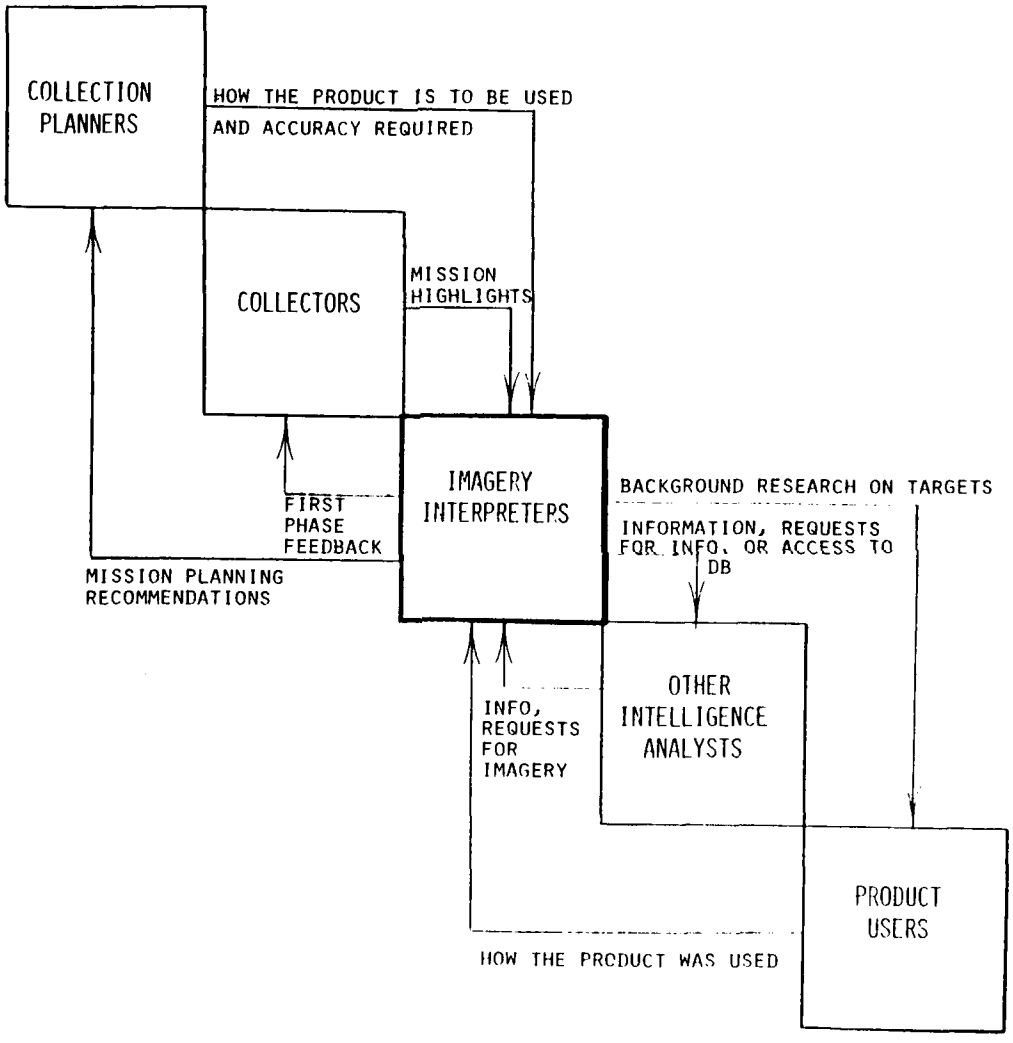

Figure 2-2. Informal Information Flow

1) communications regarding how the product will be used, and accuracy required when the requirement is issued; or

2) recognition of work well done.

2.2 Representation of IMINT Production Activities

The primary variables in determining the breakdown of IMINT production activities are mission, skill level, and time. As mentioned above, the variable of time tends to be dominant at the strategic level, where the IMINT production organizations may be described as having a mission which is single phase (in terms of the discussion of Section 2.1.3). On the other hand, tactical II facilities tend to carry out all three types of processing, depending on the operational requirements. Within both environments, assignment of analytical and reporting tasks depends on the skill level of the individual IIA. These three variables focus on different dimensions of IMINT production process, which must be represented in some way in the model.

The representativeness of the model of different types of IMINT activity also depends on the manner of observation of the IMINT production process. The time of observation of an IMINT production activity could range from a 'snapshot' of peak processing activity to a long term observation of a unit and its operation cycles. The long term observation could also be interpreted as the expected or probable assignments that an individual IIA would receive over his career in the IMINT field: i.e., covering multiple skill levels and a diversity of active missions and training in various II schools and facilities.

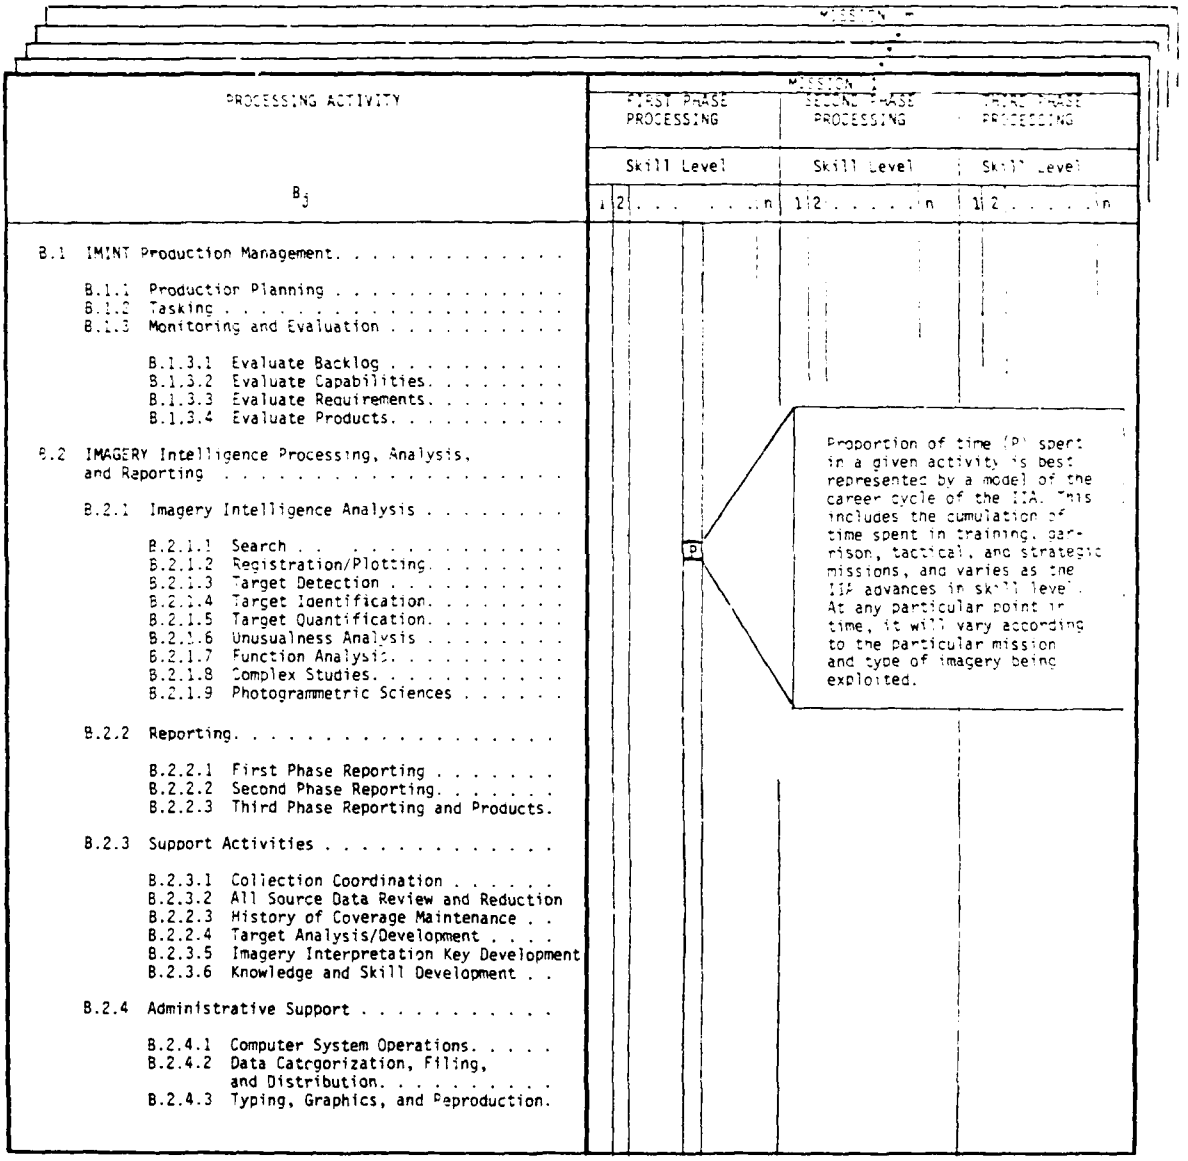
In addition to these general issues of process representation, there are several specific problems in devising a format for accurately representing IMINT production activities. Some performance steps for IMINT activities are in fixed sequence, others show high variability in sequence; some sequences are logically mandatory, others optional. Moreover, some activity steps are restricted to certain work roles and organizational slots, while others are distributed very generally; some steps occur rarely, some occur with great frequency. II analysts may be assigned concurrent processing tasks, resulting in a time-sliced, priority-driven allocation of daily activities. As a direct consequence of these practices, an analysis is needed to reflect time spent by an IIA in various processing activities. As shown in the processing activity matrix of Table 1, the activities of a given facility can be represented by the proportion of time spent in particular activities.

The formula for computing level of activity in a given task is equivalent to the statistics produced by a standard Management Information System (MIS) which keeps track of II analyst activity on an hour-by-hour basis. This type of MIS data is in fact maintained at national strategic level organizations for use in planning and allocation of personnel resources.

This form of activity representation is useful in examining crucial areas of skill development, as well as life cycle impacts of management

Table 1

IMAGERY INTERPRETATION PRODUCTION - PROCESSING ACTIVITY MATRIX



and support activities. The existence of a particular type of activity or processing task -- whatever the level of activity -- is important in determining the information structure and complexity of cognitive processing, pursuant to the ultimate objectives of this research described in Section 1.1.

The left hand column in Table 1 reflects the higher level structure of production activities in terms of staff organizations, time sequence, and processing sequence. Since facilities will tend to have more than one type of mission, this table is in fact multiplied by each type of mission.

This type of probabilistic representation of IMINT production activities has several uses:

(1) as an illustration of the diverse activities for which IIAs must be trained over the long term,

(2) as an indication of which activities analyst resources are utilized in,

(3) as a comparison of skill needs to skill training.

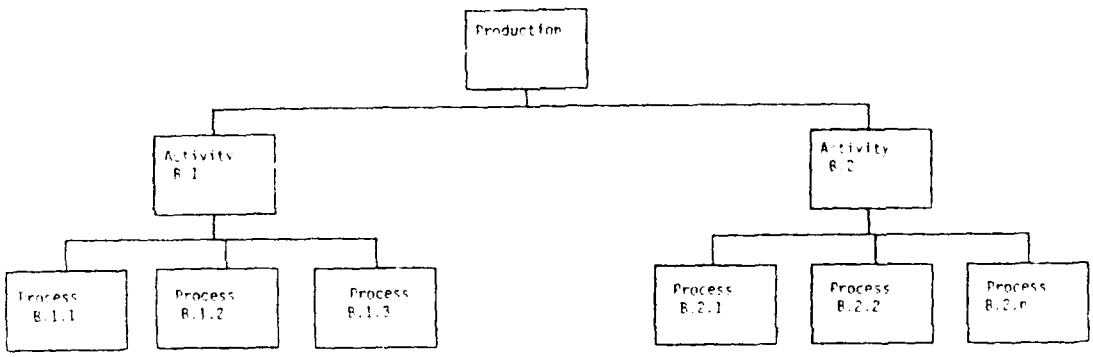
Since the model presented in this report is intended only as a generic representation of the spectrum of IMINT production processing activities, no attempt has been made to fill in the comparative level-of-activity values for individual task areas.

2.3 Process Description Format

IMINT production processes are described in Section 3.0 using the HIPO (Hierarchical Input-Process-Output) format. This format was selected over the more conventional flow diagramming format for the reasons discussed in the preceding section -- especially because the processes forming a particular IMINT production activity are not necessarily sequential. The HIPO format provides a means for systematically describing IMINT production in terms of a hierarchy of management and analytical activities. These activities are further subdivided into processes, which are in turn composed of subprocesses, where all three levels may have specific or general inputs and outputs. While the management activities described in Section B.1 of the model are not elaborated to the subprocess level, the analytical activities described in Section B.2 are specified in more detail. A further description of the conventions used in the HIPO charts on analytical activities is contained in Section B.2.1.

As illustrated in Figure 2-3, the HIPO descriptions are composed of hierarchical charts which identify major production activities, and Input-Process-Output diagrams providing in depth descriptions of each activity. The HIPO format thus presents a top-down description of the overall IMINT production process, outlining a generic IMINT production facility which encompasses a broad range of both tactical and strategic IMINT production activities.

FUNCTIONAL HIERARCHY



PLUS

INPUT-PROCESS-OUTPUT DIAGRAMS

HIPO Conventions

*An asterisk appearing in a diagram block indicates that a more detailed expansion of that block will appear in the immediately following pages.

Input 1
Input 2
Input 3

Bracketed inputs are general inputs to an activity or a process and are not specific to any particular process or subprocess; otherwise inputs are lined up with the particular process or subprocess to which they apply (similarly for outputs).

Output 2 (B.2.3.1) A model process or subprocess number appearing next to an output name indicates that the output is specifically an input to the referenced process (similarly for inputs with number references).

B.1 IMINT Production Management

IMINT production management has the function of allocating and controlling the use of II facility resources for the production of imagery intelligence. IMINT production is a technological activity. Management of a technological activity is different from managing a manufacturing process because the capabilities of the personnel are the principal factors in productivity and output product quality.

The IMINT production manager's primary control mechanisms are the assignment of personnel and the use of time (including the time between active missions).

B.1.1 Production Planning

Production planning is the set of activities involved in preparing the II facility to perform its assigned mission. For well-established strategic II facilities, the production operates according to precedents, and much of the planning information structure is unwritten. Formal planning activities are of more importance to a tactical facility in a pre-deployment stage where personnel may be less experienced, and unfamiliar with the deployment area. Planning requirements are influenced by the list of factors presented on the associated chart, which are discussed in the following paragraphs.

Mission. The mission of an Army II facility establishes which agencies task the facility and defines the facility's areas of responsibility. The mission of the facility will vary depending on resources and course of the battle in a combat situation. Area of responsibility may be defined in terms of geographic area, type of target, or imagery source.

Collection Plan. The II facility coordinates with collection planning groups and has responsibility for recommending targets and missions within the scope of their tasking. Collection planning is necessarily controlled from the big picture perspective. The ability of a particular facility to exploit specific types of imagery will influence the collection plan.

Allocation of II Resources. The II facility is tasked concurrently in many areas of imagery interpretation. The II production manager must allocate resources for different areas of tasking and support activities. The manager has responsibility for coordinating additional resources needed to meet requirements. Using estimates of current processing backlog and projected workload, the II facility manager can produce a tasking plan to assist in deciding allocation of resources.

* indicates expansion of function in following pages

Work breakdown Structure. In order to utilize specialties and available skill levels. A typical facility will have branches organized by geographic area, technical specialty, target type, imagery source, or administrative function.

Operating Procedures. Procedures for conduct of imagery interpretation processes are derivatives of procedures from handbooks, field manuals, equipment operating manuals, or standard operating procedures. In most cases, these procedures are adapted to the particular needs of a facility and its production operations. Formalized operating procedures are of more importance for training than for day-to-day production operations. Units conduct their training for processes peculiar to that facility.

Monitoring. Policies for monitoring and evaluating production processes aim at outgoing product quality and timeliness. Branch and senior level analysts are assigned to review product content and quality. Policies are established to ensure consistency in producing quality. Timeliness of products is monitored by estimating production time and maintaining regular status checking of progress and analyst workload.

Priority Policy. Priority policies aid the facility in handling a mixture of imagery interpretation requirements with varying timeliness constraints. Priorities are adjusted when necessary to meet product suspense times.

Reporting Policy. Policies are established for the type of reporting vehicle to be used, classification of content, and distribution. Policy provides general guidelines, each report being evaluated individually on its own merit under the particular circumstances.

Product Standards. Product standards vary with respect to allowable production time, priority of requirement, extent of distribution, and resources available for production. A product may be a typeset and printed report with professional graphics, a reproduced photograph with attached notes, a record message, or an informal teletype or telephone response to a specific user.

II Skill Development Planning. In order to accomplish the IMINT production with which it is tasked, an II facility is assigned a complement of personnel who have the requisite levels of skill to operate IMINT products that meet the standards for the particular type of facility mission. The II facility staff composition may include personnel with formal training only at skill levels 1 and 2 and rotating personnel with no experience in the local mission. Some positions in the II facility may be unfilled. The II facility has the responsibility of providing unit training to adapt its available staff to the local mission and to general Army standards for the II MOS.

General standards are set by the Department of the Army in terms of the Skill Qualification Test (SQT) for promotion to higher rank in the II specialty area. Requirements for advancing in the II's analyst's specialty area may require a broader range of skills than normally needed for day-to-day tactical unit operations. Unit training must be broad in scope to insure the individual IIA's development for future mission requirements. The II facility management must plan the use of time between active missions for skill development via exercises, special training, cooperation with analysts in other technical areas, expanding the knowledge base of geographic or cultural features and conducting basic intelligence research. Although much of the responsibility for skill development rests on the individual analyst's own initiative, management must encourage this endeavor and allocate time and resources to support those activities as a normal function of the facility operation.

B.1.2.2
ASSIGN PRIORITIES
B.1.2.3
ALLOCATE TASKS TO BRANCH/ ANALYST
B.1.2.4
APPROVE PRODUCT RELEASE
B.1.2.5

B.1.2 Tasking

The function of the tasking process is to delegate processing tasks to individual II analysts, management, and support personnel as the II facility develops its workload. Production planning establishes the general work breakdown structure and responsibilities of individuals but workload may vary as a function of time. The product goals for the facility are established by the II mission.

The tasking process is a complex decision-making activity, because limited personnel resources must be allocated to produce multiple products with limited varying timeliness requirements. The personnel limitations are not just in numbers, but in skill levels and prior experience with the target type or geographic area. As a result, the tasking activity is one of balancing requirements and production priorities against capabilities. In order to make the most efficient use of available resources, tasking is performed under the following general guidelines.

(1) time-sensitive requirements are addressed first;

(2) organization of tasking into geographic or target-oriented branches to make maximum use of analyst prior knowledge;

(3) rating of interpretation tasks by skill level requirements so that appropriate skill levels can be used whenever possible;

(4) division or organization to provide special support groups not requiring II skills;

(5) time variant priority scheme which allows periodic production tasks to gain priority as their suspense date nears;

* indicates expansion of function in following pages

(6) monitoring of production time for previous products and estimating production time for new work allows management to control total workload of the facility. The tasking manager can refer to these workload estimates in deciding whether new requirements can be accepted or in initiating requests for additional resources;

(7) using non-peak production periods for pre-mission preparation, training, knowledge base development, or other support tasks;

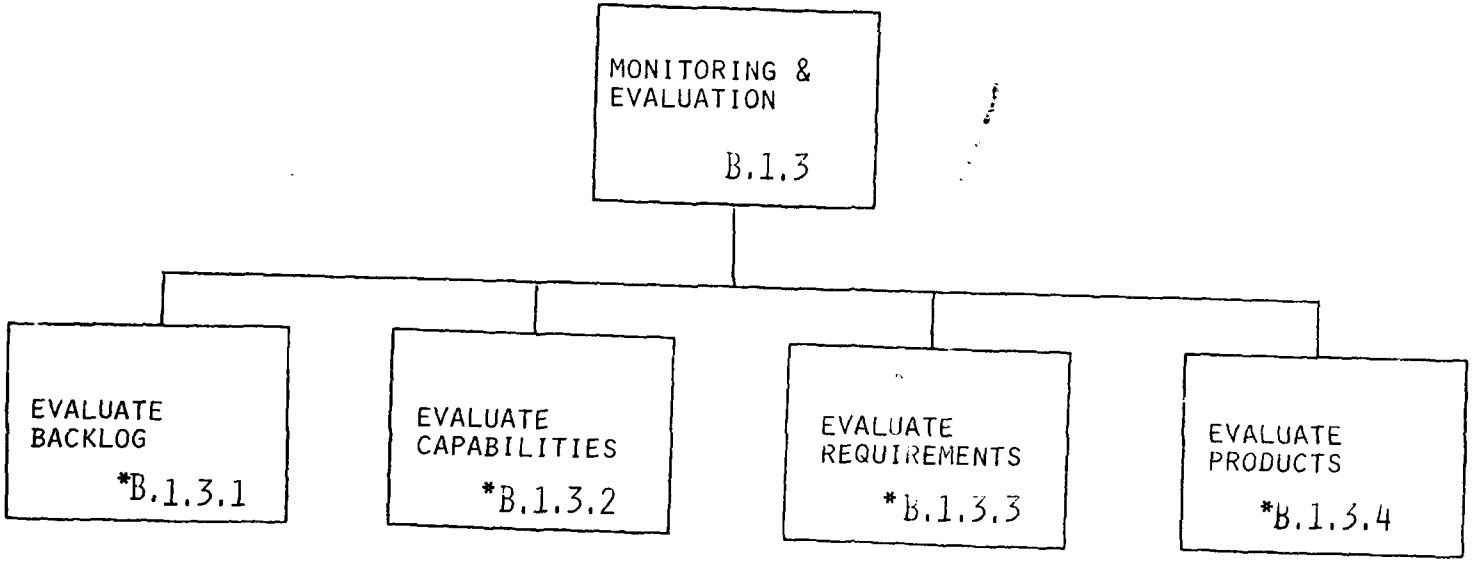
(8) informal technical assistance among analysts within the facility.

The actual control of tasking is a combination of 1) established work breakdown by branches within the II facility and specialties of analysts, 2) directed tasking in response to new requirements and 3) allocation of time for tasks.

Assigned Targets. An II may have continuing responsibilities for surveillance in a particular area, or for monitoring particular targets. Tasking is automatic whenever the area or target is covered. Continuity in target following is an essential factor in the cognitive capabilities required for unusualness analysis change detection, and identification processes (B.2.1.4.6). Continuity in following target types or a geographic area allows the II to build a data base of related collateral materials and a broader knowledge base of the technical or cultural/geographic area.

Direct Support Tasking. Army commands or other users with direct tasking authority may levy special case requirements. These requirements are evaluated and given priorities; estimates of workload are generated; and tasking assignements are made within the facility.

Management and Support Activity Tasking. In addition to imagery interpretation tasks, management activities and support activities must also be explicitly tasked. The division of labor within the II facility is designed for efficient use of resources but correspondingly creates a larger organization to be managed with additional branches to be tasked. Supporting activities such as skill development and collateral material collection are more heavily tasked during non-peak production periods.



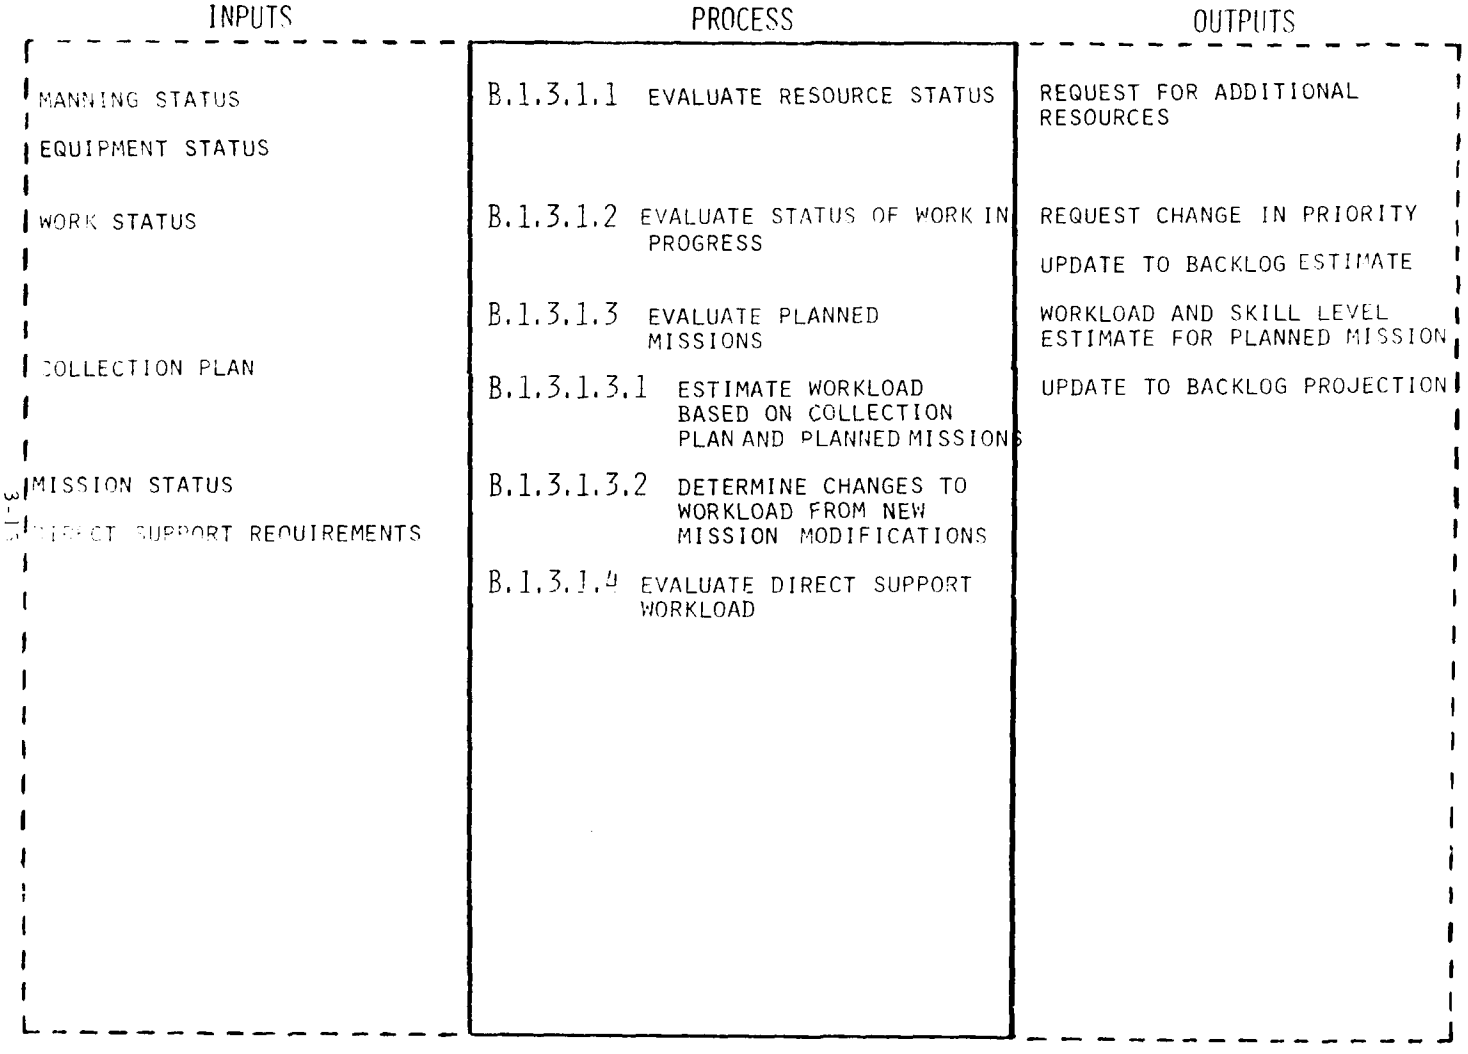
*INDICATES EXPANSION OF DETAIL IN FOLLOWING PAGES

B.1.3 Monitoring and Evaluation

Monitoring of product quality and processing status provides feedback information to the IMINT production manager for planning and tasking. Monitoring and evaluation also provides feedback to the II analyst in terms of his performance and time available to complete his task. IMINT production overall is a highly adaptive process that can trade product timeliness against product quality.

Monitoring and evaluation activities are functionally oriented toward backlog, capabilities, requirements, and products. These four areas are detailed in hierarchical INPUT-PROCESS-OUTPUT (HIPO) in order to show the flow of information necessary to manage the II production process.

B.1.3.1 EVALUATE BACKLOG



* indicates expansion of function in following pages

B.1.3.1 Evaluate Backlog

The II facility, whether in a tactical environment or deployed at the national strategic level, will be subject to a cyclically varying time pressure for production output. It is essential that the II facility manager monitor not only the work in progress but the workload that will accrue from planned missions and regular reporting requirements. The priority scheduling system allows the II facility manager to exploit the cyclical nature of collection missions to produce periodic reports or basic intelligence products when there is a lull in mission activity. It is the responsibility of the monitoring function to recognize when a task is behind schedule and request an adjustment in priority to ensure completion of the task.

The backlog projection provides the II facility manager with the information necessary in deciding if he has sufficient resources to support the collection plan. If a significant difference exists between the collection plan and the II facility capabilities, coordination will be initiated to resolve the difference.

B.1.3.2 EVALUATE CAPABILITIES

SUPPORT ACTIVITY STATUS	B.1.3.2.4	EVALUATE SUPPORT CAPABILITIES	RECOMMENDATIONS FOR CHANGES TO SUPPORT ACTIVITY TASKING

* indicates expansion of function in following pages

B.1.3.2 Evaluate Capabilities

The II facility is able to adapt to new operating environments and changing requirements by continual evaluation of its own capabilities for production. Capabilities are of concern in the areas of procedures and equipment, staff skill levels and knowledge base, imagery, and support capabilities. The following paragraphs describe the processes shown in the associated chart for the evaluation activity.

B.1.3.2.1 Evaluate Equipment and Procedures

Procedures for interpretation, equipment operation, and report preparation are based initially on standard operating procedures from handbooks and field manuals. These procedures need regular evaluation and updating to reflect new techniques and peculiarities of the changing operating environment. Procedures must be appropriate within mission and time constraints.

B.1.3.2.2 Evaluate Staff Capabilities

II analysts are the most critical component of the production process. II skills represent a technology which is developed through training, working experience, technical exchange with peers, and knowledge base development in specialty areas. Imagery interpretation is such that evaluating an II process is virtually impossible without redoing the entire process for comparison. Effective utilization of a staff with varying skill levels is achieved by organizing work in terms of skill level requirements. Apprentice IIAs may work with an experienced analyst and teams of II analysts may be assigned to complex tasks. In the majority of interpretation activities, the IIA will have sole responsibility for his performance. The success of this method depends on analysts initiating requests for assistance when encountering difficult problems or targets which are unfamiliar to them, and analysts of all skill levels are encouraged to confer with peers. Individual IIAs are frequently identified with specific IMINT reports. This personal identification is an aid to users who may request additional data or clarification, and is a means of giving professional recognition to the individual. Monitoring and support of staff development is recognized as an effective means of upgrading the capabilities of the II facility. Personal attention to skill development needed for promotion and career advancement is a major factor in optimizing production capability. The high technical proficiency gained by Army trained II analysts is readily marketable as a civilian skill. This factor combined with limited career opportunities in the Army II skill specialty frequently results in high staff turnover rates.

B.1.3.2.3 Evaluate Collection Capabilities

Because the II facility is partially dependent on its collection sources for its product impact, there must be feedback mechanisms between the II facility and the collection systems. To support this information feedback channel, the II facility engages in a variety of collection capability evaluations aimed at maximizing exploitation of these sources. The most important feedback mechanism appears to be the informal coordination which takes place at the analyst level rather than the management level.

Mutual understanding of capabilities is essential in maximizing the exploitation of imagery. Interpreters have flown reconnaissance missions in order to appreciate the problems of the reconnaissance pilot. Pilots in turn may work with interpreters in evaluating the success of the collection missions and gaining feedback on how improvements can be made.

B.1.3.2.4 Evaluate Support Capabilities

Supporting activities may be as vital as interpretation processes to the production capabilities of the II facility. These activities (described in B.2.3) must be tasked and monitored. Where production conflicts occur in support activities, priorities are assigned.

B.1.3.3 EVALUATE REQUIREMENTS

INPUTS	PROCESS		OUTPUTS
II FACILITY MISSION REQUIREMENTS	B.1.3.3.1	EVALUATE REQUIREMENTS RELATIVE TO II FACILITY MISSION	ACCEPT OR REQUEST CHANGES IN REQUIREMENTS
HISTORY OF COVERAGE (B.2.3.3)	B.1.3.3.2.	DETERMINE IF EXISTING IMAGERY CAN BE USED	IDENTIFIED IMAGERY FOR INTERPRETATION TASK (B.1.2.2)
MISSION PLANS	B.1.3.3.3	DETERMINE IF NEW COLLECTION MISSIONS ARE REQUIRED	RECOMMENDED INPUTS TO COLLECTION PLAN

* indicates expansion of function in following pages

B.1.3.3 Evaluate Requirements

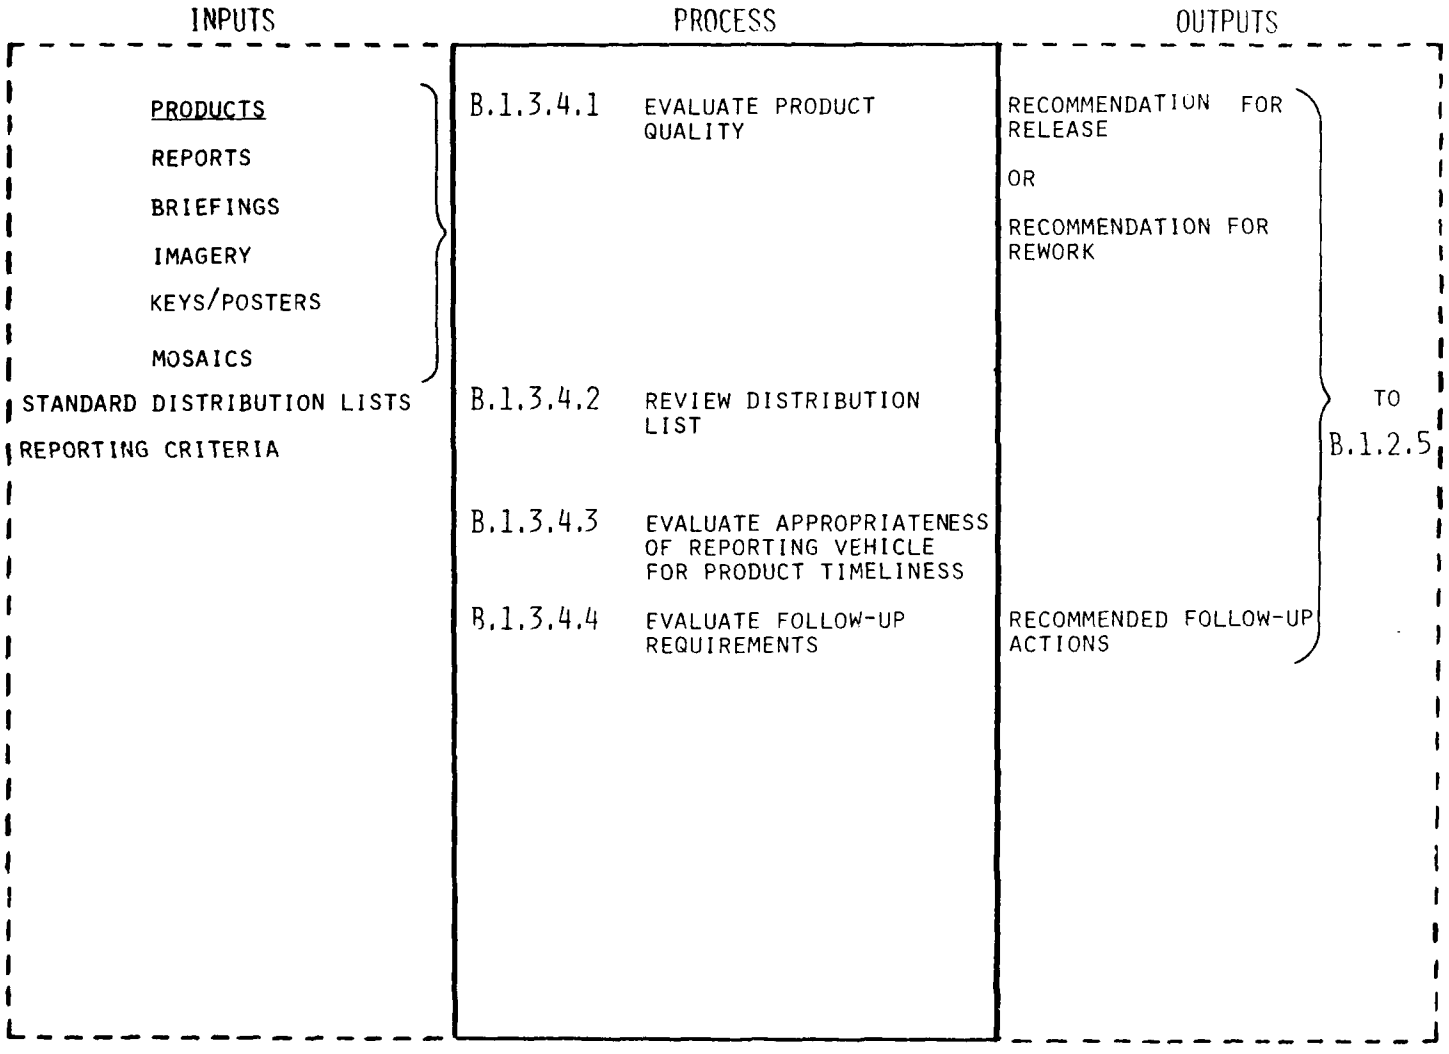
Requirements for imagery intelligence are diverse and may be received from a number of different tasking agencies. Requirements may be categorized into one of three general types: standing, direct support, or basic intelligence.

Standing Requirements. Imagery interpretation requirements that are relatively fixed over time are referred to as standing requirements. A standing requirement may require following of particular target types or surveillance of particular areas of interest. Reporting requirements may be on a periodic schedule, reported each time coverage occurs, or on an unusualness basis. Standing requirements are usually reflected in the facility mission statement. Standing requirements are evaluated on the basis of their impact on processing load and collection requirements.

Direct Support. The II facility generally has in its mission the requirement to provide direct support to various authorized tasking agencies. Direct support requirements involve all three phases of interpretation production and vary in priority and complexity. Direct support requirements must be evaluated carefully from a mission standpoint so that overlapping interpretation tasks do not occur between facilities.

Basic intelligence. Imagery interpretation is utilized to produce a wide variety of basic intelligence such as order of battle. The II facility may be tasked with providing inputs to basic intelligence files or preparing Basic Imagery Interpretation Reports (BIIRs). Characteristically, basic intelligence tasks are more complex, take longer to process, and involve extensive use of all-source intelligence materials.

B.1.3.4 EVALUATE PRODUCTS

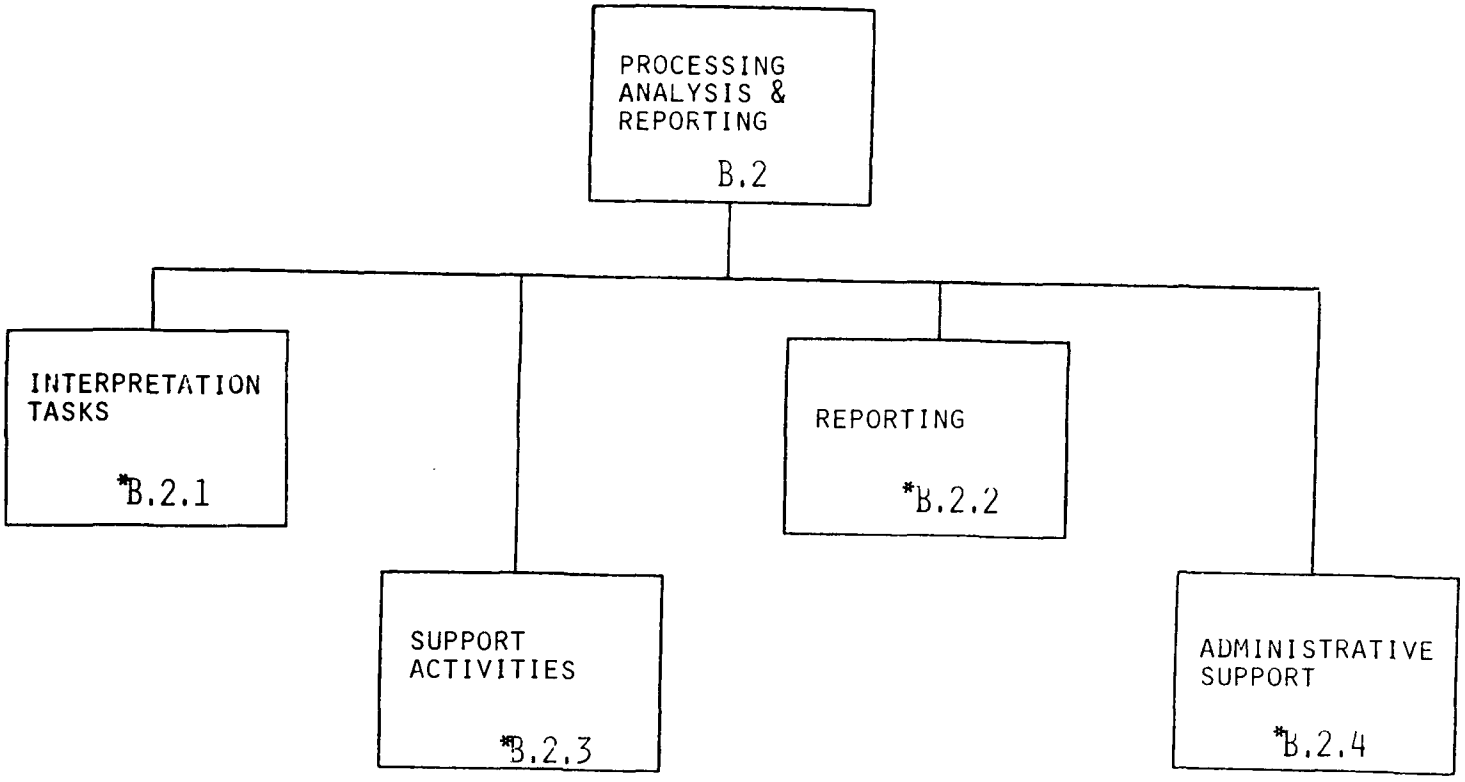


* indicates expansion of function in following pages

B.1.3.4 Evaluate Products

All products are reviewed prior to release for distribution with the exception of informal technical exchange between analysts. Products are reviewed for grammatical and technical quality, correctness of distribution, classification level, and reporting vehicle. In some cases reviewers may be able to also look at the source imagery. This is not practical in those cases such as search or complex studies involving a large amount of imagery. Review tasks are normally handled by senior analysts, branch chiefs, or a technical area review committee. Quality standards, report formats, reporting policy, and standard distribution lists are used as references in the product review process.

Certain types of products require follow-up actions. Follow-up reports may be required to expand the detail in an immediate report; or, collection plan modifications might be appropriate as a consequence of a product's content.

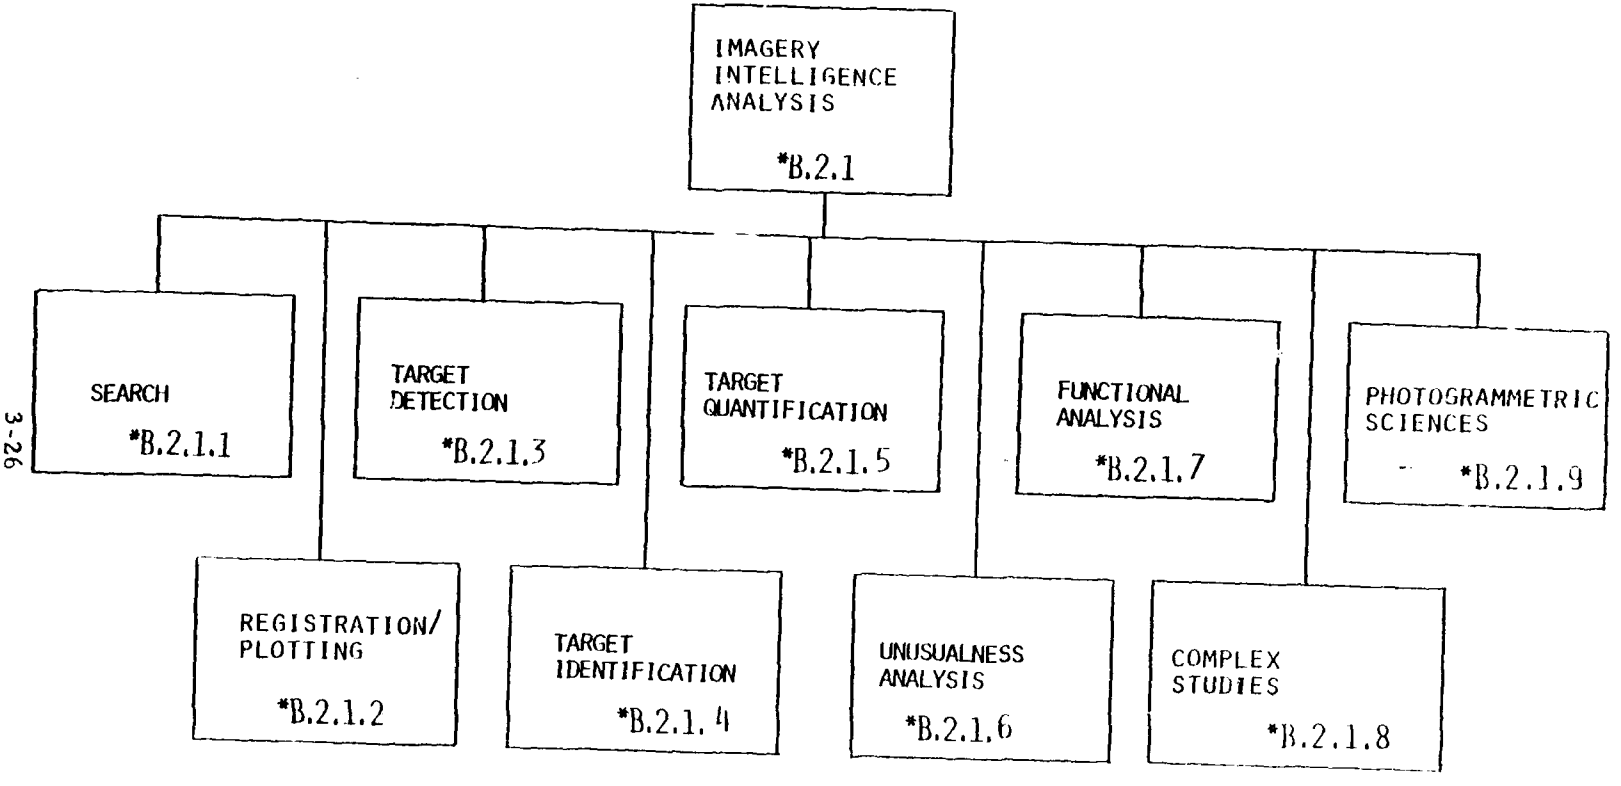


*INDICATES EXPANSION OF DETAIL IN FOLLOWING PAGES

B.2. Imagery Intelligence Processing, Analysis, and Reporting

The imagery intelligence production activities described in part B.1 of the model deal with planning, tasking, and evaluation of the product. Although the impact of those activities upon the analytical and reporting activities discussed here in part B.2 is substantial, the latter activities are of primary interest in this model, since specification of the analytical, cognitive and judgmental content of the activities described below is fundamental to the development of a cognitive model of intelligence analysis (see Section 1.1). In fact, the title of this part is selected to facilitate comparision with analogous SIGINT activities, referred to as Processing, Analysis, and Reporting (PAR) in the model document [Ref. 8] used for a preliminary investigation of SIGINT activities involving cognitive processing.

The Processing, Analysis, and Reporting activities of an imagery intelligence production facility are organized along lines of skills and function, and are further segmented in terms of product suspense times that allow the IMINT production process to adapt to different loading conditions and operating environments. The major areas of activity are analysis, reporting, support activities, and administrative functions. These areas of activity are readily observable in larger II facilities and less distinct in smaller facilities where staff functions are more general. These subdivisions of activity are important from a tasking point of view, because the level of activity shifts dramatically between these areas over time. Short term variations will occur on an hourly, daily, and weekly cycle during normal operations. Larger shifts in activity will occur as the facility experiences mission changes due to the dynamics of the international situation, with concomitant changes in intelligence collection and tasking.



*INDICATES EXPANSION OF DETAIL IN FOLLOWING PAGES

B.2.1 Imagery Intelligence Analysis

As an introduction to the analysis of imagery, several issues which are generic to the variety of analytical activities shown on the facing page merit discussion. These include the concept of imagery analysis as opposed to 'bean counting', and the constraints imposed on the analytical process by time, the quality of the imagery, and the knowledge and experience of the IIA assigned to a particular task. In addition, the chart format for describing the analytical activities is described.

The Imagery Interpretation Process

The imagery interpretation process essentially consists of identification of physical objects, such as equipment, in the context of its environment, which includes associations between such equipment and the function of the military unit that uses it, leading to identification of such a unit -- e.g., engineering equipment indicates the presence of an engineering unit, possibly a headquarters. In addition, characteristics or conditions of interest (e.g., the modification of terrain by excavation) should be identified; -- and to the extent possible -- activities, such as bridge construction, river crossing training, which may reveal the intent of the enemy. These sets of objects, conditions, and activities are of interest because they have military significance: in the broad sense of the word, they are potential targets for military exploitation. Use of the term 'target' in the following discussion is intended to convey this broader meaning, rather than a particular installation in a targets file as a specific target, since such an installation in fact may contain a large variety of objects and equipments which are targets in themselves.

As mentioned above, the imagery interpretation activity involves to some extent the association of objects with other objects (e.g., a type of support equipment with a particular type of missile), the association of (equipment) objects with a known T&E configuration of equipment (e.g., six 120 mm mortars indicates a battery, seven indicates two batteries), the association of equipment with an organizational unit of a particular size (e.g., one mortar battery may indicate a motorized rifle battalion while two could indicate the presence of a motorized rifle regiment), the association of equipment with function, and consequently, with a degree of threat (e.g., a SAM on a launcher is ready to fire, a SAM on a transporter is not). All of these associational processes require deductive reasoning, and distinguish the function of imagery interpretation from simple 'bean counting'.

The Time Factor

Imagery interpretation analysts are aware of these inferential processes and can apply them to the categories of targets within their competence. However, the depth of analysis is often severely limited by the length of time available to perform the analysis. An IIA preparing Hot Photo Interpretation Reports (HOTPHOTOREPs) in a Tactical Imagery Interpretation Facility (TIIF) may have only a few minutes to actually analyze imagery, since substantial segments of the time period from engine shutdown to report filing deadline must be devoted to film processing and to registering, plotting, and validating the mission trace. Time is thus a critical limiting factor in the analysis which provides the basis for a HOTPHOTOREP. This limitation is compensated by the additional analysis which optionally follows, resulting in a supplement to the original HOTPHOTOREP within the next hour. The problem is that such supplements have lower priorities than the HOTREPs themselves, so should additional missions continue to arrive, no further analysis on an earlier mission already covered by a HOTREP is possible.

Although the above scenario is tactically oriented, the inverse relationship of time and depth of analysis also exists on the strategic level. In fact, the three temporally defined phases of IMINT processing described in Section 2.1.3 are applicable to both tactical and strategic environments. Many IIAs on both levels are concerned with the preeminence of the time factor over analytical performance, even in the third phase, basic study context. Others seem to have accepted time constraints as an occupational parameter, and do not appear to be unduly concerned with the possibility of missed information.

The Quality of Imagery

An important aspect of IMINT analysis is that imagery utilized by any facility -- whether a local TIIF or a national imagery interpretation resource -- will not have consistent quality. Sensor and platform capabilities, range, height, and atmospheric conditions all contribute to wide variations in the quality of imagery. Each IIA essentially evaluates imagery from the perspective of his own processing task, in order to determine the extent to which the image can be exploited in the context of that task. For example, a 50% cloud coverage on an area would reduce the effectiveness of an imagery interpretation search function by 50%, but may or may not affect particular targets within the imagery frame. For oblique imagery, near objects would have better resolution and could thus be more accurately identified than remotely located objects. Haze produced from various causes might obstruct identification of certain objects, but not others.

For these reasons, an IIA cannot usually anticipate the quality of imagery related to his interpretation tasks until he is actually viewing a particular segment of imagery. Productivity is not affected by this lack of prior evaluation in tasks which require search of previous imagery files. Methods are currently being established for evaluating imagery products across the broad range of imagery interpretation applications. In particular, a national standard, called the National Imagery Interpretability Rating System (NIIRS), has recently been implemented on the national level; this standard will presumably be adopted in some form on all imagery interpretation echelons in the near future.

Knowledge and Experience of the Individual IIA

An additional factor in IMINT analysis is the set of experiences, background, and knowledge that an individual IIA brings to bear on a particular analytical task. A new IIA who has previously served in the infantry or artillery has an advantage in identifying equipment and in knowing where to look for it. Such a person may also be able to infer enemy intent from the disposition of equipment and personnel, thus providing an in depth analysis of an enemy situation that would be very difficult for a novice IIA with a civilian background to duplicate. Similarly, an IIA with experience in a strategic level II position in an active mission will have acquired a detailed background in a specific area relevant to that mission, which may or may not be directly exploitable in a tactical environment. For example, equipment relevant to strategic missions does not generally include US or NATO equipment, which is used in tactical exercises. Thus equipment learned in detail in the course of a strategic assignment may not be directly relevant to a tactical assignment; however, the methodological knowledge and experience of analyzing equipment of any kind is an important part of the knowledge base of an IIA, and gives the IIA with strategic experience an advantage in performing tactical or strategic imagery analysis. The IIA in a tactical assignment is a generalist, prepared to deal with any imagery analysis task. Basic Army IIA training therefore includes course blocks dealing with targets which are not normally Army responsibilities, such as ports, harbors, inland waterways, and strategic industries. On the other hand, strategic level assignments tend to be more specific, requiring an IIA to become an expert in a particular set of targets or types of equipment.

Presentation of Analytical Activities in HIPO Charts

In the following discussion and associated charts, the set of imagery analysis activities is segmented functionally for convenience of analysis in terms of cognitive processes underlying particular functions, in line with the larger context of the cognitive model for intelligence analysis for which this II model has been constructed (see Section 1.1). An IIA in the field may in fact perform the whole range of activities at some level in the course of a typical work day. Moreover, the detection, identification, quantification, and unusualness analysis activities (B.2.1.3-6) are performed to some level in all phases of interpretation, although the more detailed analysis represented by the functions identified as B.2.1.7-9 (where B.2.1.8 includes such functions as Order of Battle, terrain, and entry zone analysis) are essentially third phase, less time sensitive, activities.

Partition of Information Handling versus Analytical Processes in Charts

The chart presentations of the majority of these activities differ from those of the preceding section in level of detail and process segmentation. The charts are more detailed and the majority are organized in terms of a segmentation into information manipulation processes versus analytical processes. As an illustration, Figure 3-1a treats information handling processes for the target detection activity, and identifies an analytical process which is expanded into subprocess descriptions in the following chart (signaled by an asterisk), shown in Figure 3-1b.

The inputs of the information handling activities are general mission requirements on the one hand, and on the other, Specific Requests for Information (SRI), and interpretation priorities driving the particular activity in a given case (for example, the the EEI at a given point in time in a particular situation). The outputs of the information handling processes -- for example, the acquisition of imagery and relevant reference materials shown by the processes labeled b.2.1.3.1-4 in Figure 3-1a -- have as outputs the given imagery and materials aligned in the output column with the associated processes. These outputs are labeled with the analytical process (B.2.1.3.5) to which they are sent, and appear as inputs to that process in Figure 3-1b, labeled with the number of the process which generated them. The outputs of the given analytical process then are sent to the next activity, B.2.1.3.4, Target Identification, and are simultaneously sent to reporting (B.2.2).

It should be remembered, as discussed in Section *.1, that all the listed processes may not occur in any given case, or may not be performed in the sequence in which they are listed. In many cases, time pressure or lack of reference materials eliminates one or more of the information acquisition steps, while many of the analytical processing steps may be performed essentially simultaneously, or omitted as irrelevant in a given case.

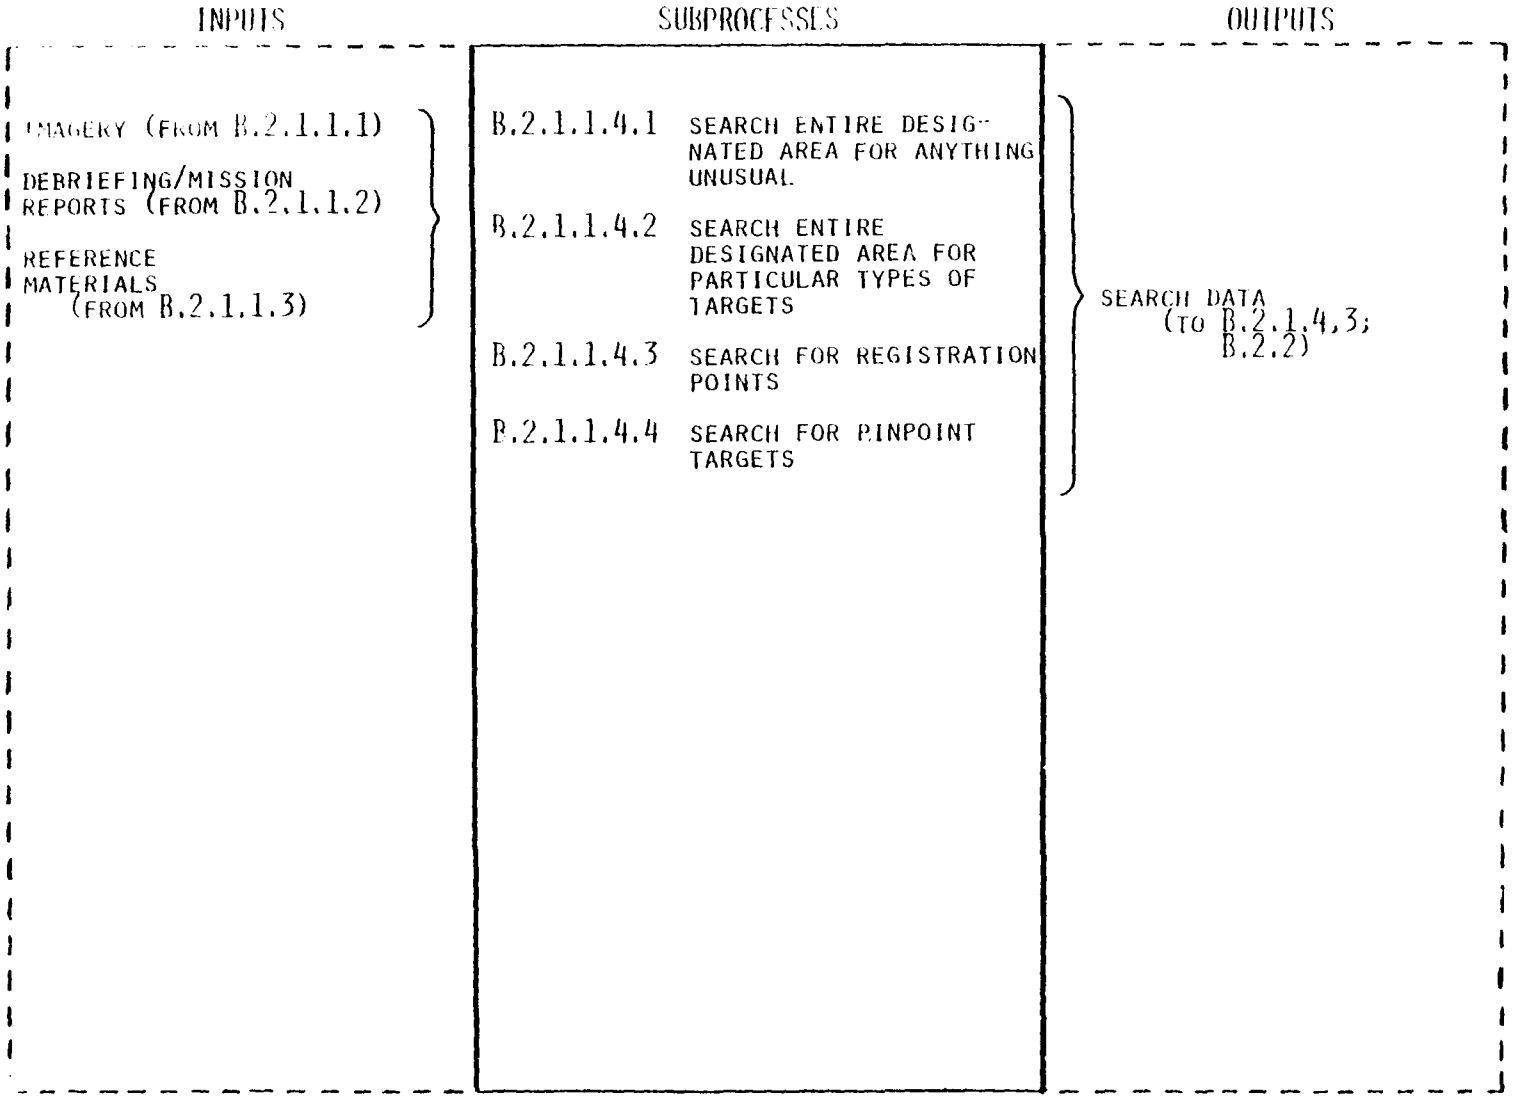
B.2.1.1 Search

The following description of the imagery analysis activity assumes two modes of search, as well as the three phases of interpretation discussed above. The two modes of search are general or 'accountable' search (as it is described on the strategic level), and specific search for selected items. General search is driven by all-inclusive mission or tasking requirements, by which a particular imagery interpretation element must account for all targets in its functional and geographic areas of responsibility, examining every square inch of film within a given period of time after receipt of imagery. Specific search, on the other hand, is driven by Specific Requests for Information (SRI), limiting the scope and objectives of the search. Both types of search are characteristic of the imagery interpretation process at the level of the tactical unit, as well as at the level on which national strategic and service-wide imagery interpretation resources operate.

B.2.1.1.4 PERFORM SEARCH PROCESSING



* indicates expansion of function in following pages

B.2.1.1.4 Perform Search Processing

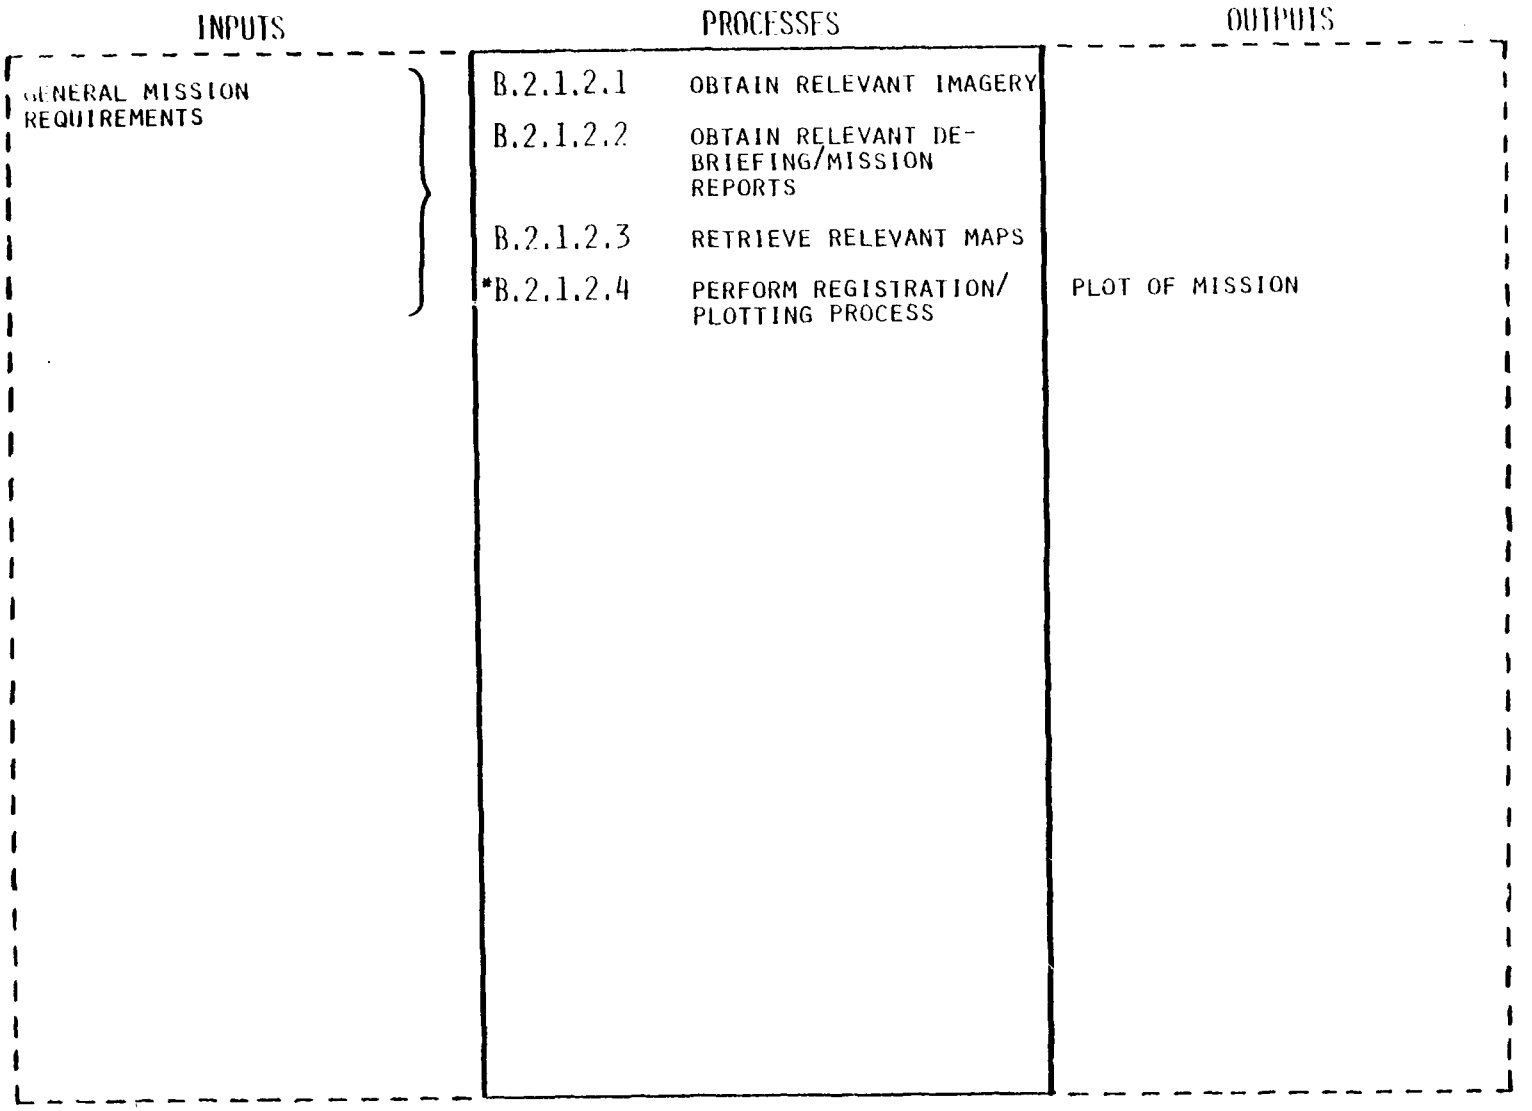
The search activity is differently practiced at the various levels of the IMINT production effort. On the level of national strategic imagery interpretation resources, search is more closely associated with unusualness analysis and change detection (see B.2.1.6 for discussion). The search activity as practiced there is a specialized form of accountable search, in which special techniques and equipment are used to simulate 'flying' over the imagery on a light table. As every square inch of the film is 'overflown', the IIA looks for unusual aspects of the terrain or known targets in the area to determine whether any changes have occurred since the last imagery was obtained. If possible changes are detected, a retrospective search of previous imagery is performed to pinpoint the time at which the change occurred by locating imagery antedating the particular unusual characteristic. Thus if an excavation for a possible missile silo is noted, comparative cover imagery will be examined to 'negate' the excavation condition: i.e., to determine the date of coverage when such a condition did not exist, in order to bracket the time frame within which the change occurred. A second aspect of accountable search involves specific checking for new targets of a particular type, assigned as a functional responsibility to an individual IIA or an IIA group.

On the level of the tactical II facility, an analogous type of search activity occurs. An example of this search related to unusualness analysis and change detection is provided by tactical image interpretation operations in Vietnam. Imagery analysis was generally segmented by geographical area and, in most cases, sufficient image interpretation capability was available to allow fairly small areas to be assigned to individual IIAs. These IIAs thus tended to become experts in their particular area of responsibility, which meant that they could easily distinguish objects and configurations associated with the Vietnamese cultural background from objects and configurations of military significance (e.g., grave mounds from weapons emplacements). In a careful search of every inch of film from each new mission flown, the experienced IIA could notice anything at all unusual (for example, possible camouflage), or immediately detect the slightest change in his area of responsibility ("I could tell if they'd moved one tree," a veteran IIA said).

A similar type of search activity associated with target detection (see B.2.1.4) is practiced in tactical units performing real time processing of imagery produced by Side-Looking Airborne Radar(SLAR), Forward-Looking Infrared (FLIR), and video devices. Also, where an aircraft was directed to photograph between coordinates rather than to photograph pinpoint targets, a detailed search of the film precedes the analytical activities of target detection, identification, etc.

In addition, the registration and plotting activity involved in tracing the route flown by a reconnaissance aircraft is also preceded by a type of search activity -- in this case, a search of the imagery for registration points required to calibrate the mission photography with the IIA's map and with the pilot's concept of the route flown in the particular mission. Similarly, a search precedes the detection and identification of pinpoint targets photographed on a particular reconnaissance mission.

B.2.1.2 REGISTRATION/PLOTTING



* indicates expansion of function in following pages

B.2.1.2 Registration/Plotting

Before an IIA can begin to detect or identify targets photographed in the course of a tactical reconnaissance mission, the strip of film which is to be analyzed must be registered with the IIA's map and a preliminary plot of the mission trace must be made. Registration involves identifying features on the film which correspond to prominent features on the map likely to endure for some period of time (i.e., terrain features, man-made features such as roads, urban areas, airfields, etc.). Once the film has been registered to the IIA's map, an approximate plot of the mission can be prepared, using code matrix data on the film as necessary to determine specific coordinates.

The first phase registration and plotting activities are extremely important in an environment where an II facility is associated with a tactical reconnaissance squadron -- for example, a collocated MIBARS detachment in a temporary deployment for the purpose of an exercise, or on permanent assignment to a tactical air base. In this environment, most imagery interpretation tasking is directed at immediate readout of aerial photographic missions, where the registration/plotting activity provides the vital parameter of location to the analytical and reporting activities that follow immediately, all three activities (as well as film processing) being accomplished usually within an hour of engine shutdown.

B.2.1.2.4 PERFORM REGISTRATION/ PLOTTING PROCESS SUBPROCESSES

INPUTS		OUTPUTS
IMAGERY (B.2.1.2.1) DEBRIEFING/MISSION REPORTS (B.2.1.2.2) MAPS (B.2.1.2.3)	B.2.1.2.4.1 LOCATE PERMANENT FEATURES ON IMAGERY B.2.1.2.4.2 ORIENT PERMANENT FEATURES ON IMAGERY TO IDENTICAL FEATURES ON MAP B.2.1.2.4.3 LOCATE STARTING POINT OF IMAGERY B.2.1.2.4.4 DETERMINE PATH COVERED BY MISSION B.2.1.2.4.5 CONVERT GEOGRAPHIC TO UTM COORDINATES	

* indicates expansion of function in following pages

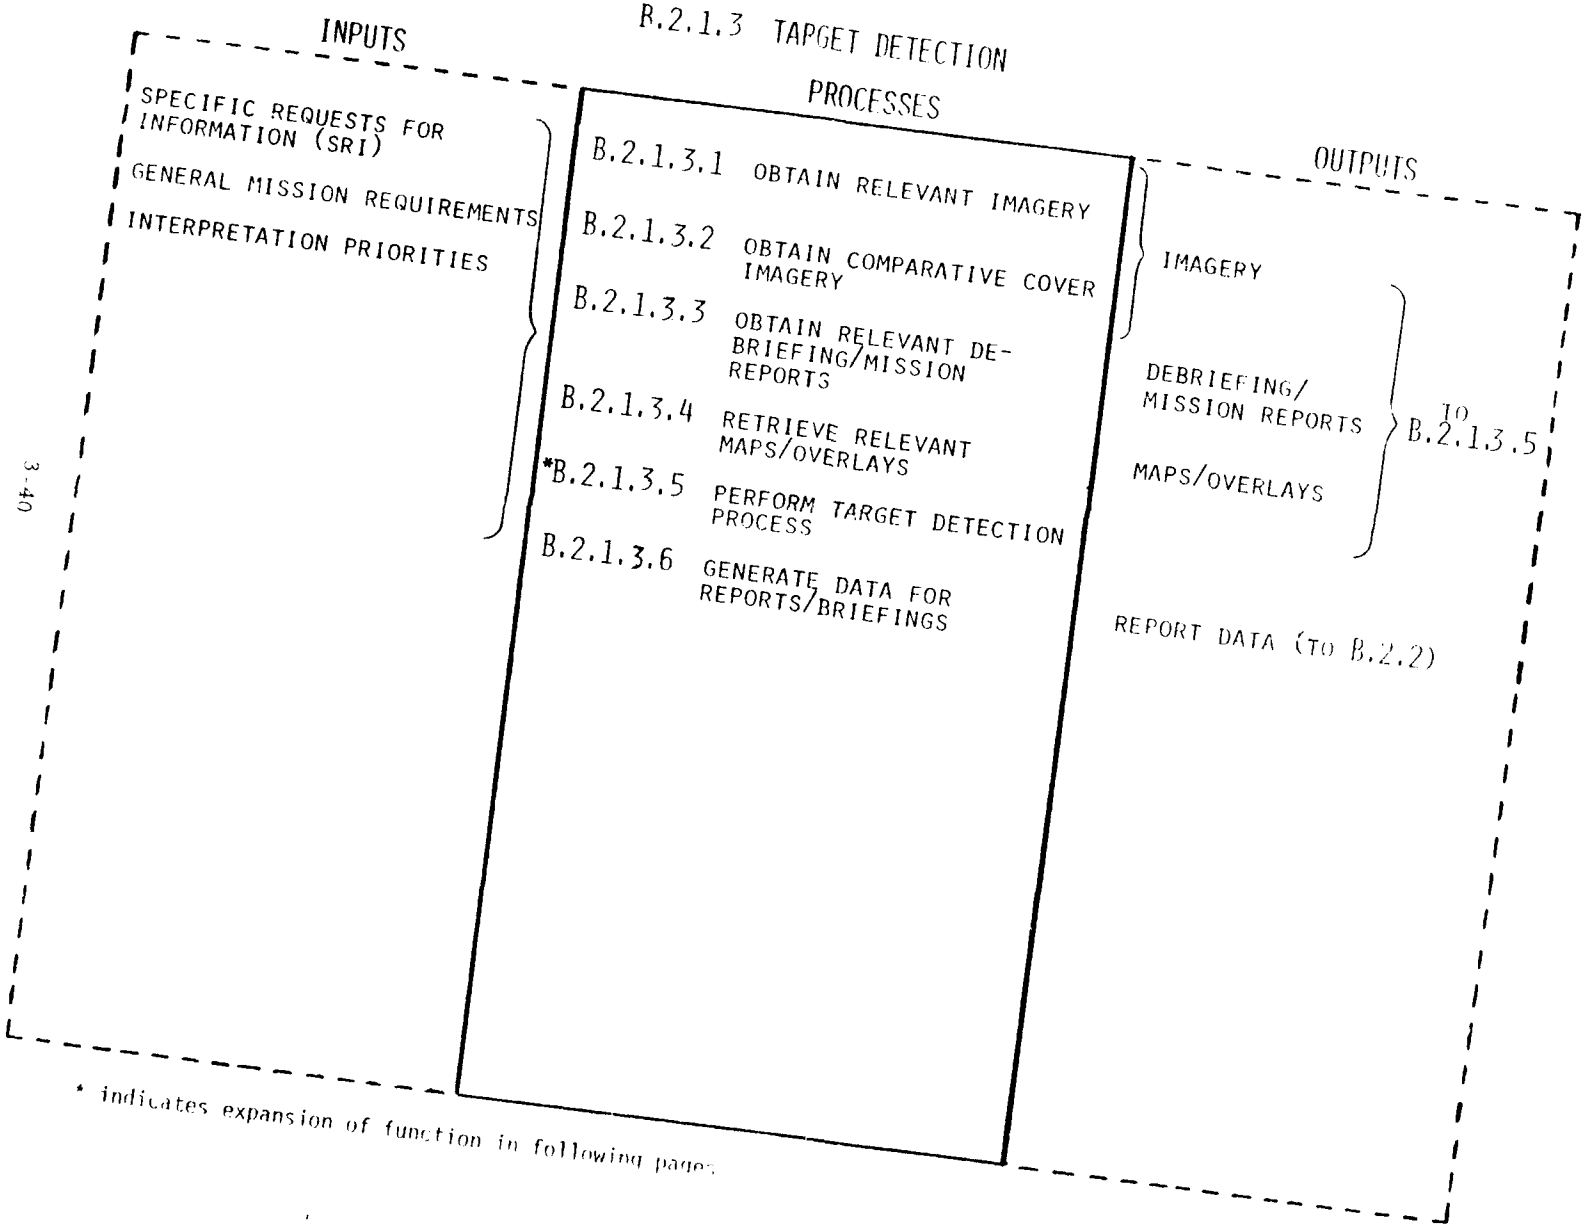
B.2.1.2.4 Perform Registration/Plotting Process

In theory, the basis for this activity is the pilot's trace of the mission flown, as well as the ARLO's debriefing and the mission report or MISREP (which, in the training exercises observed, was substantially prepared before engine shutdown, from the mission plan and inflight reports received from the pilot).

In practice, the pilot and/or navigator appear in the II facility as soon as the imagery has been developed, and the orientation of the mission imagery to the IIA's map is carried out with the active participation of pilot and/or navigator, in the interest of making the most rapid assessment of the mission for a Hot Photo Interpretation Report (HOTPHOTOREP).

The difficulty is that the reconnaissance mission may not have covered the area identified in the mission plan, nor photographed the targets in the planned sequence, nor turned the cameras on and off at the planned points. Weather, enemy fire, and other considerations may change planned coverage. The orientation/registration problem involved in plotting the mission is complicated by such factors, and the difficulty of registering the mission in terms of a map is inversely proportional to the number of salient features in the area of mission coverage. For this reason, IIA's in a MIBARs detachment have estimated that the registration and plotting of a mission occupies about 80% of the time spent in active interpretation, report preparation the next highest percent of time (around 15%), and analysis of the imagery, the smallest proportion of image interpretation time.

The plotting function is also an important second phase function, where accuracy is emphasized (see B.2.3.3). On the national resource level, the plotting function is required for first and second phase analysis of all imagery produced by airborne platforms.



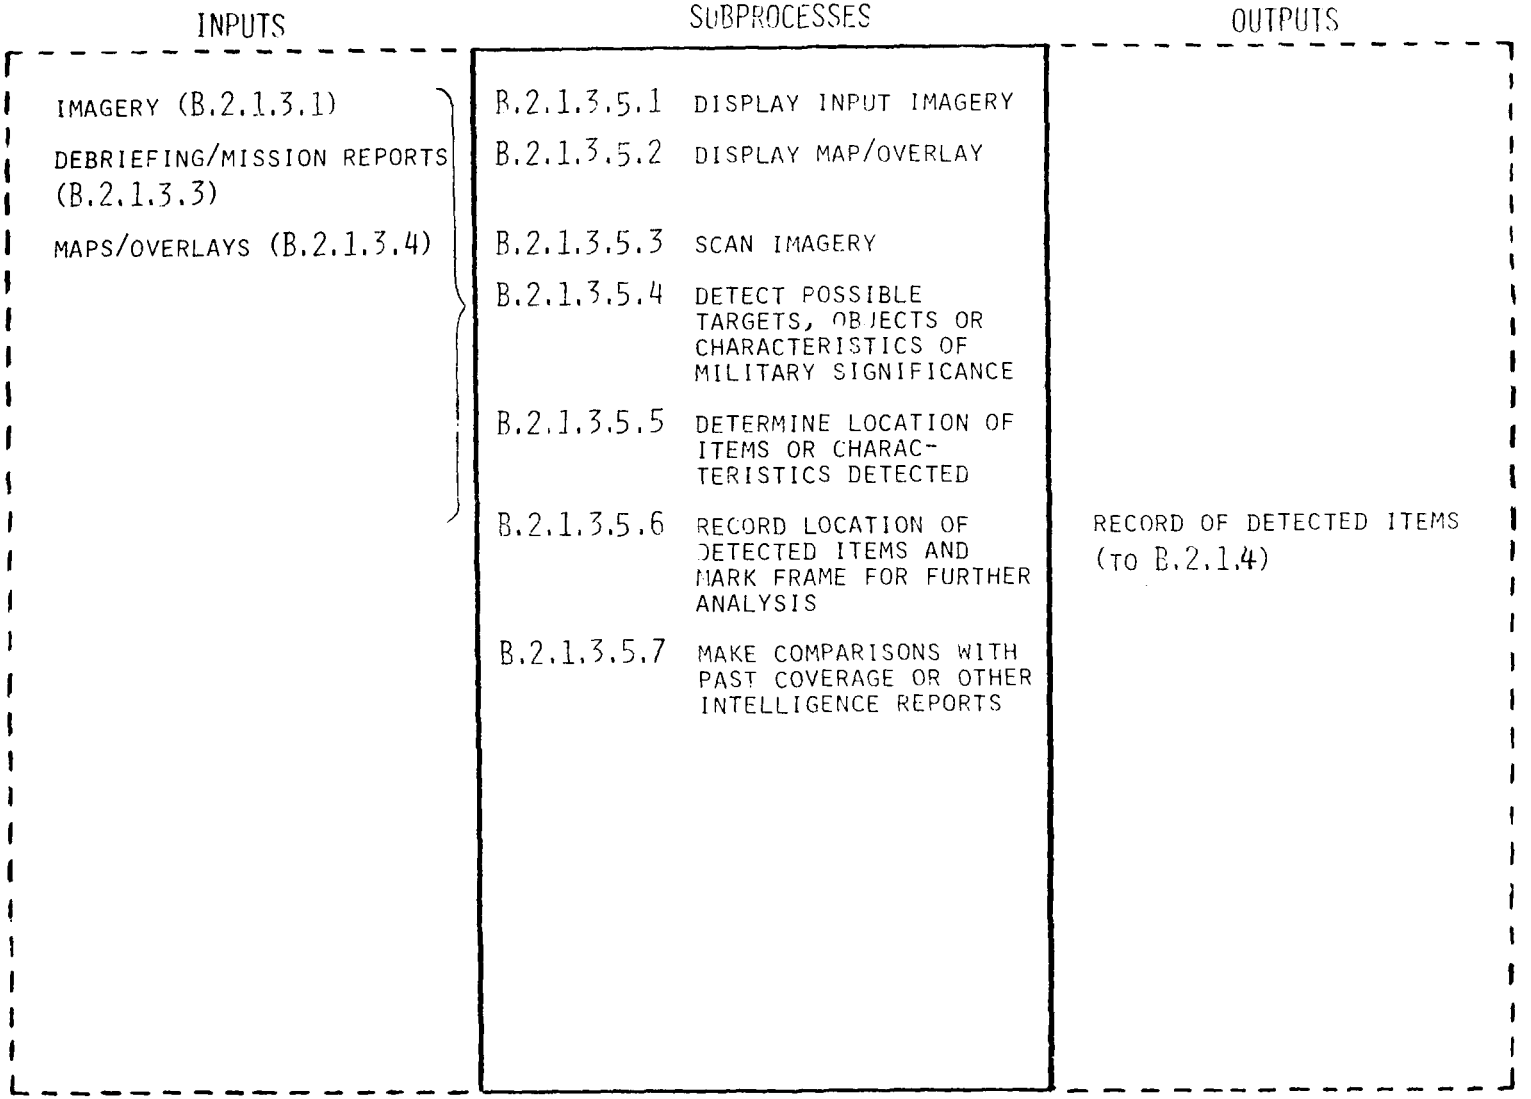
* indicates expansion of function in following page

B.2.1.3. Target Detection

Target detection is essentially the perception of a potential target, which is then validated through the identification activity (B.2.1.4). The activity of target detection includes real time imagery analysis (e.g., involving Side-Looking Airborne Radar (SLAR), Forward-Looking Infrared (FLIR), or video devices), or interpreting wet or dry film under less severe time constraints. In dynamic processing of SLAR imagery, the image interpretration activity is limited to detection of probable moving targets via the Moving Target Indicator (MTI) capability of the SLAR, as identification of the particular target as armor, personnel transports, etc., is not possible. SLAR systems -- when provided with ground-based or airborne interpreter stations to perform detection in real time -- can be exploited for quick response targeting and area activity monitoring.

In the case of SLAR interpretation then, the necessary information for target identification is not present in the medium, thus the analytical activities of detection and identification are distinct, conforming to the separation of these two activities in the model. Since the necessary information for identification is usually present in the case of infrared imagery (IR), video or film (whether real time or not), the distinction between the detection and identification activities is somewhat arbitrary, as some type of identification will usually be made simultaneously with detection. When the visual cues constituting the necessary information for identification are not present -- for example, when the quality of the imagery is low -- identification requires additional analysis involving comparative cover imagery, keys, etc., such that the detection and identification activities are functionally separate, as presented here.

B.2.1.3.5 TARGET DETECTION PROCESS



* indicates expansion of function in following pages

B.2.1.3.5 Target Detection Process

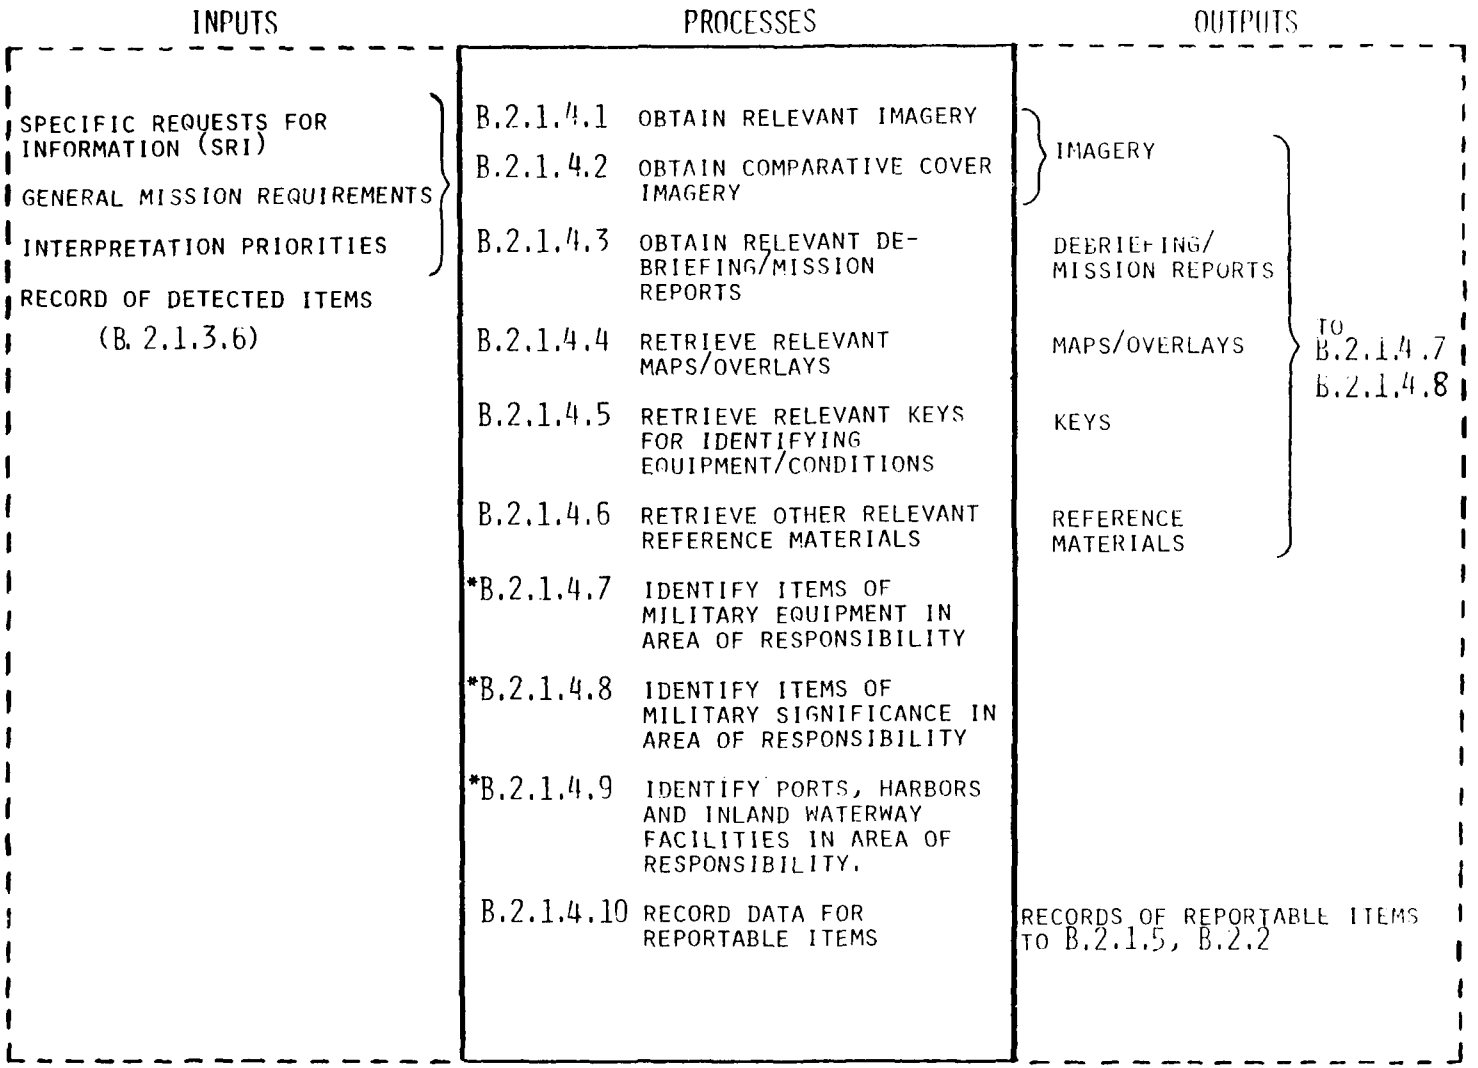
For first phase search, the preliminary screening function associated with detection generally does not involve comparative cover imagery, reports, imagery interpretation keys, or other reference materials because of the time critical nature of such scans, exemplified on the tactical level by the initial screening for items requiring generation of a HOTPHOTOREP. A minimum of comparative material -- e.g., a SITMAP -- is used to detect changes in the location of moving targets.

In second phase search, (roughly, within 24 hours) exemplified on the tactical level by search for items meriting an 'Immediate' report, there is sufficient time to utilize aids and reference materials for more precise and detailed reporting.

In third phase interpretation, the detection effort is largely directed at guaranteeing that no reportable items in the functional and geographic areas of responsibility of the particular imagery interpretation element have been missed in the previous, time-constrained, scans (for example, because of camouflage or concealment practiced by non-friendly forces).

Thus, time-critical reporting of items detected may involve only the recording of an approximate location and marking of the particular frame of imagery for further analysis, identification, and quantification, while less time sensitive scans are directed at full exploitation of available imagery, based on all available data. The latter type of detection processing can therefore include the so-called 'negation' analysis, where the coverage history of an object or condition is followed to the point before the item appeared.

B.2.1.4 TARGET IDENTIFICATION



* indicates expansion of function in following pages

B.2.1.4 Target Identification

The identification of targets is the primary activity of an IIA. It consists in interpreting the visual cues or distinctive features of imaged objects and terrain conditions in order to determine their identity. The distinctive features are analyzed using the five 'S's (size, shape, shadow, shade, and surroundings). The depth of analysis involved in target identification is highly dependent on the time constraints for completion of the identification process. An object may be tentatively identified as a medium tank, without specifying what type of tank it is, in order to produce a HOTPHOTOREP indicating a change in an area where no armor was previously noted. Where time is less critical, careful and complete identification of equipment and its implications (e.g., headquarters unit in area) can be carried out using all available reference data and analytical aids.

In performing the identification function (especially under time pressure), the problems of errors of invention, misidentification, and missed information must be considered. Suppose an IIA mistakes rectangular grave mounds for weapons emplacements or grain stacked in shocks as a minefield pattern, or logs and debris on a river for small boats. These inventive errors could result in the sending of forces against such false targets at no small cost, economically or tactically speaking, to the commander.

Another problem involves missing a target representing a potential threat -- e.g., a SAM site -- by interpreting it as an object having no military significance. The cost of missing such information is proportional to the threat associated with the given target: failing to identify a tank is presumably less costly (tactically and economically) than missing a SAM site.

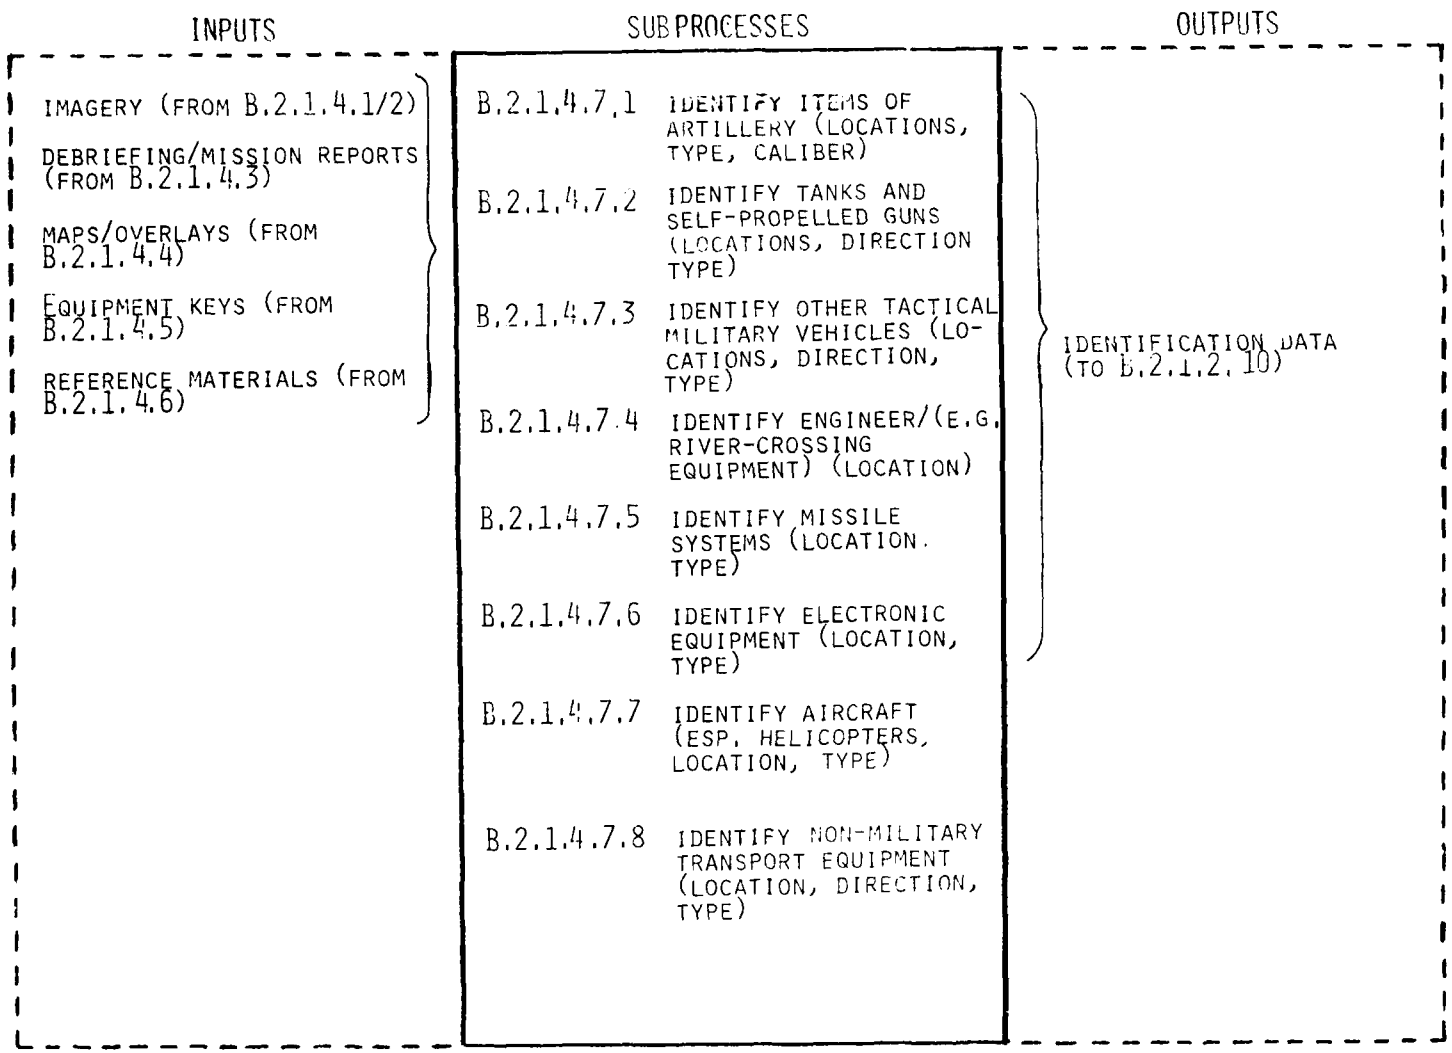
The cost of misidentification errors (identifying one type of military object as another) is also associated with the potential threat represented by the misidentified object. For example, identification of a missile transporter as another type of transport trailer could be serious in the absence of other information indicating the presence of missiles in the the area of interest.

The use of error keys, such as the key designed by ARI for use in Vietnam [Ref. 24], can be more productive than "rights" keys in avoiding interpretation errors in some cases. Both error and "rights" key products are designed to encourage use even in time-critical reporting situations.

Also, IIAs tend to specialize in identifying and reporting particular classes of targets, and are often functionally organized along these lines. Responsibilities may be assigned only for particular types of equipment and conditions, improving identification accuracy and timeliness, but also requiring that multiple scans be made of the same imagery. Any type of available intelligence to aid in confirming target identifications or guiding hypotheses as to probable areas of operation or associated units is exploited by the IIA in searching for and identifying targets. Of particular importance is the IIA's knowledge of 'surroundings' -- the fifth 'S' in image analysis. The concept of surroundings includes associations between types of equipment and between equipment and organizational units mentioned above (B.2.1). Thus some types of targets imply the presence of others, leading to a more detailed investigation of the particular imagery.

Apart from the IIA's internal knowledge of targets and associations and the external knowledge sources represented by keys, reference materials, and comparative cover imagery, an extremely valuable external knowledge source is embodied in other IIAs. Although IIAs are highly individualistic in their approach to interpretation and in their information acquisition behavior (see B.2.3.2), they are essentially team workers who respect the ability of fellow IIAs and utilize their knowledge in areas where they feel the need of assistance or expert opinion. This attitude is consistent with the experienced IIA's concern and feeling of responsibility for the acquisition of knowledge by novice IIAs (B.2.3.6).

B.2.1.4.7 IDENTIFY ITEMS OF MILITARY EQUIPMENT



* indicates expansion of function in following pages

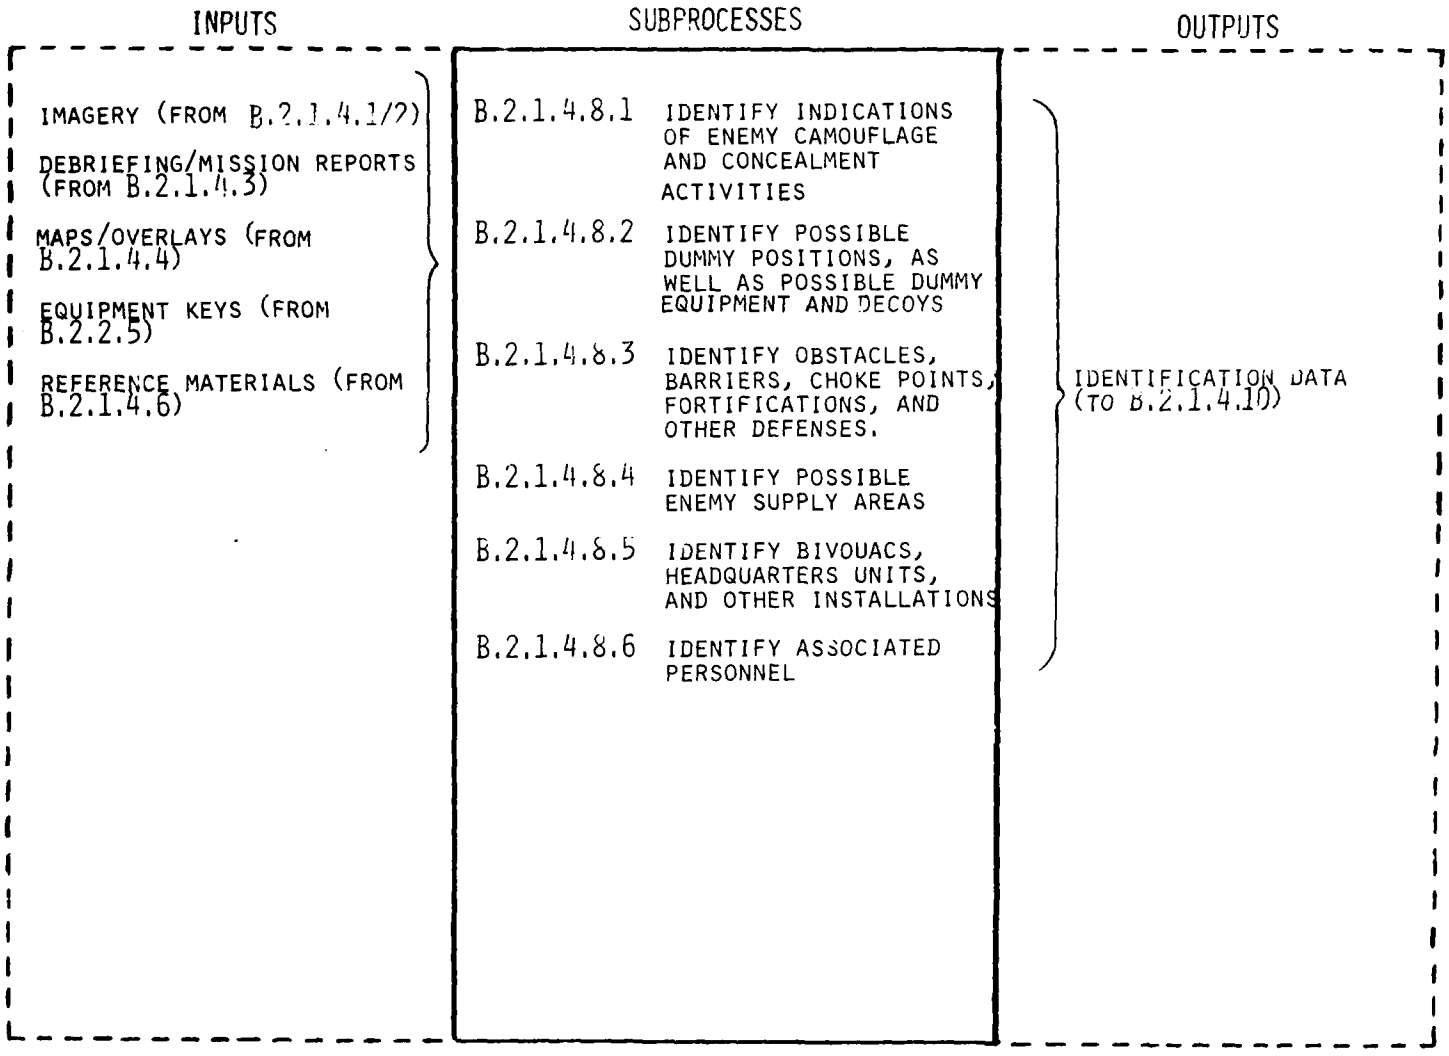
B.2.1.4.7 Identify Items of Military Equipment

The major classes of military equipment a tactical IIA is concerned with are artillery, wheeled vehicles (non-military as well, since these may also be used for military purposes), tanks and self-propelled guns, special types of engineering equipment, CBR equipment, missile systems, electronic equipment, and aircraft. In identifying mobile items of military equipment, IIAs are also concerned with determining direction of movement, and noting changes in location and direction from previously reported activities and condition (e.g., state of combat readiness -- a missile observed on a transporter versus a missile on a launcher).

In third phase interpretation at the strategic level, identification of equipment, both in development and deployed, is carried out on an extremely detailed level, in support of analytical activities aimed at developing an extensive knowledge of foreign technology.

In evaluating equipment and the important factor of 'surroundings', the association between equipments, and between equipments and organizations leads to detailed searches of the imaged area, as noted under B.2.1.4.

B.2.1.4.8 IDENTIFY ITEMS OF MILITARY SIGNIFICANCE

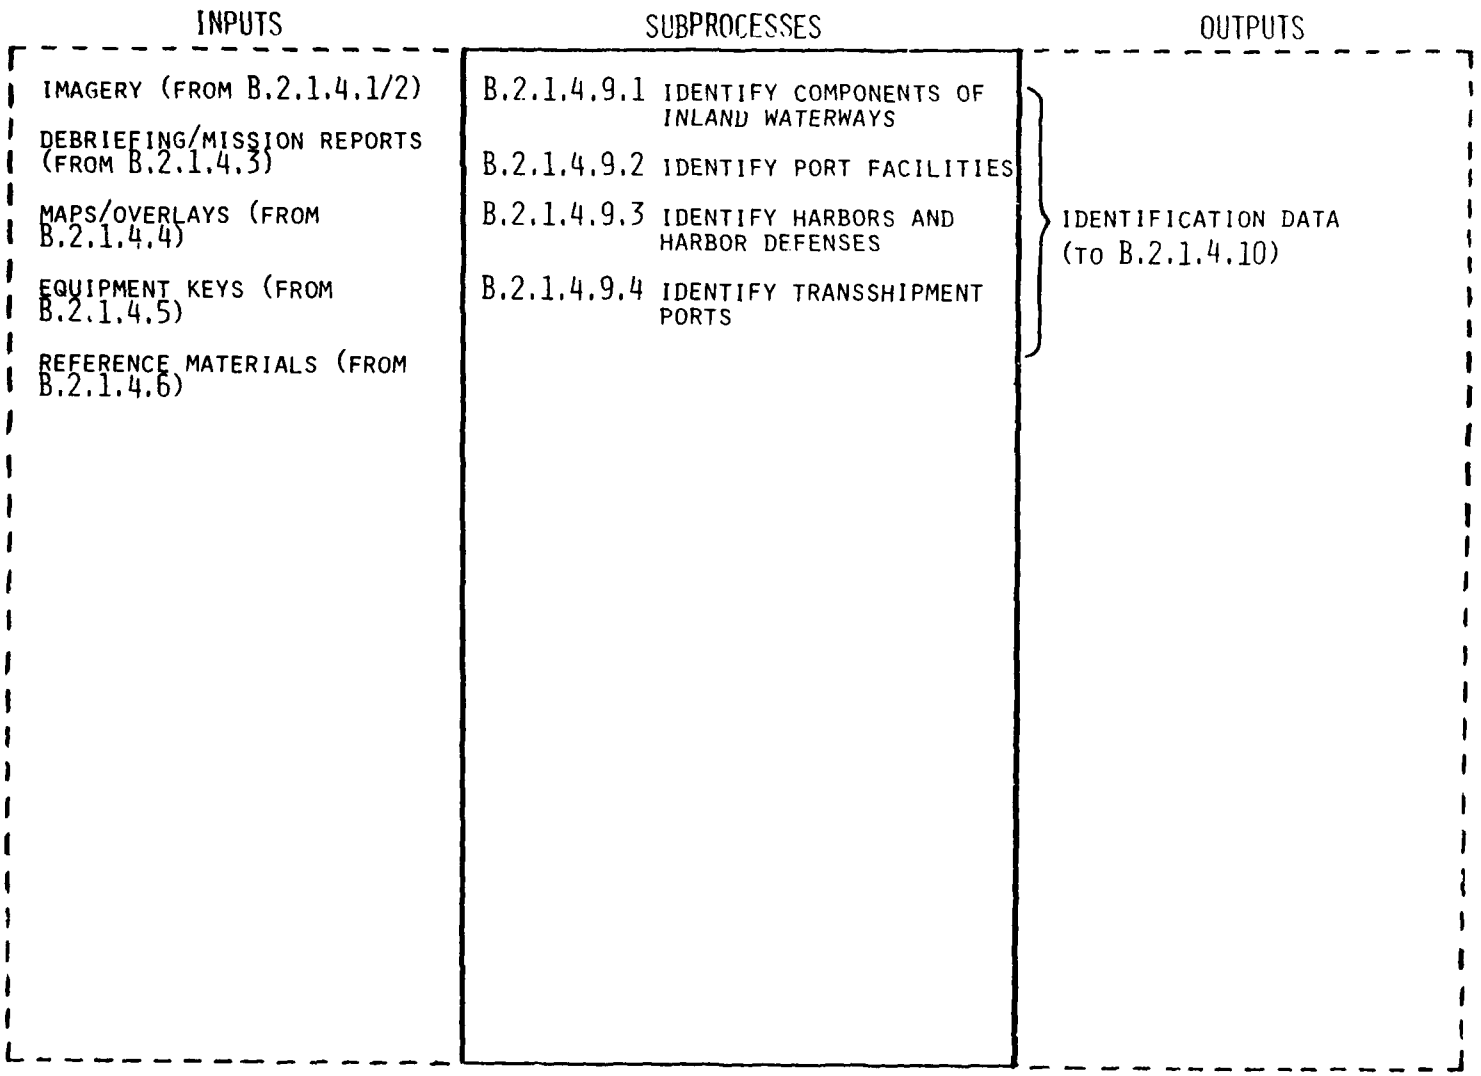


* indicates expansion of function in following pages

B.2.1.4.8 Identify Items of Military Significance

In addition to items of military equipment, all objects, characteristics and conditions of military significance must be identified, using the IIA's personal knowledge of distinctive features of items of military significance, in terms of the principles discussed under B.2.1.4. A particularly important task involves the determination of the presence of indicators of camouflage and concealment, since such activities may cause reportable objects or conditions (e.g., an excavation for a missile site) to be missed. Other indications of attempted deception, such as dummy positions, equipment, and decoys are also extremely critical in terms of establishing intent of unfriendly forces. Other important objects and conditions of military significance to be identified include route-associated items such as barriers, obstacles, and choke points, having significance both for enemy and friendly movements. In addition, enemy supply areas, bivouacs, headquarters units, installations, and associated personnel must be identified and reported.

B.2.1.4.9 IDENTIFY PORTS, HARBORS, AND INLAND WATERWAYS



* indicates expansion of function in following pages

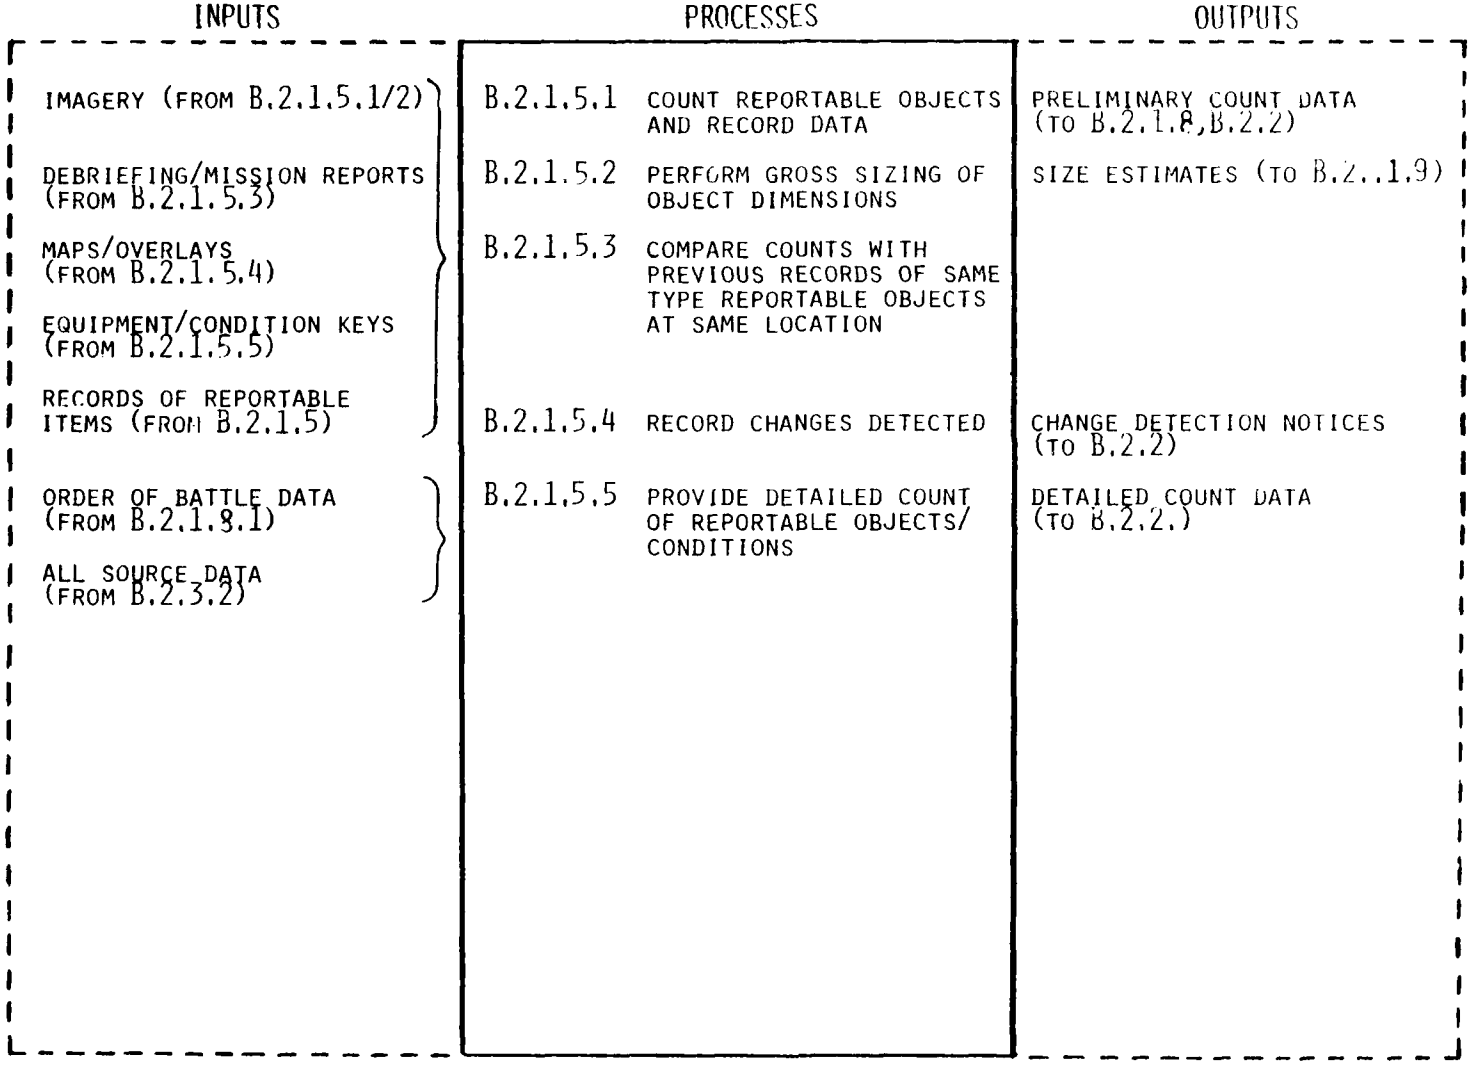
B.2.1.4.9 Identify Ports, Harbors, and Inland Waterways

Although the analysis of port and harbor targets tends to be a naval responsibility at the national level, the tactical image interpreter is expected to be a generalist. If such port and harbor facilities exist in the planned area of operations, the image interpreter must be able to analyze and report on them. Especially important are evidences of transshipment of military equipment and material, POL supplies, and other logistics information of military significance.

The basic image interpretation course taught at Fort Huachuca thus includes the identification and analysis of port and harbor facilities among the subject blocks presented.

Analogously, although strategic analysis of such naval facilities is primarily a naval responsibility in the national tasking, transshipment ports associated with particular targets (e.g., missile test ranges) are an important source of information on status of development and readiness, and target activity of reporting significance.

B.2.1.5 TARGET QUANTIFICATION



* indicates expansion of function in following pages

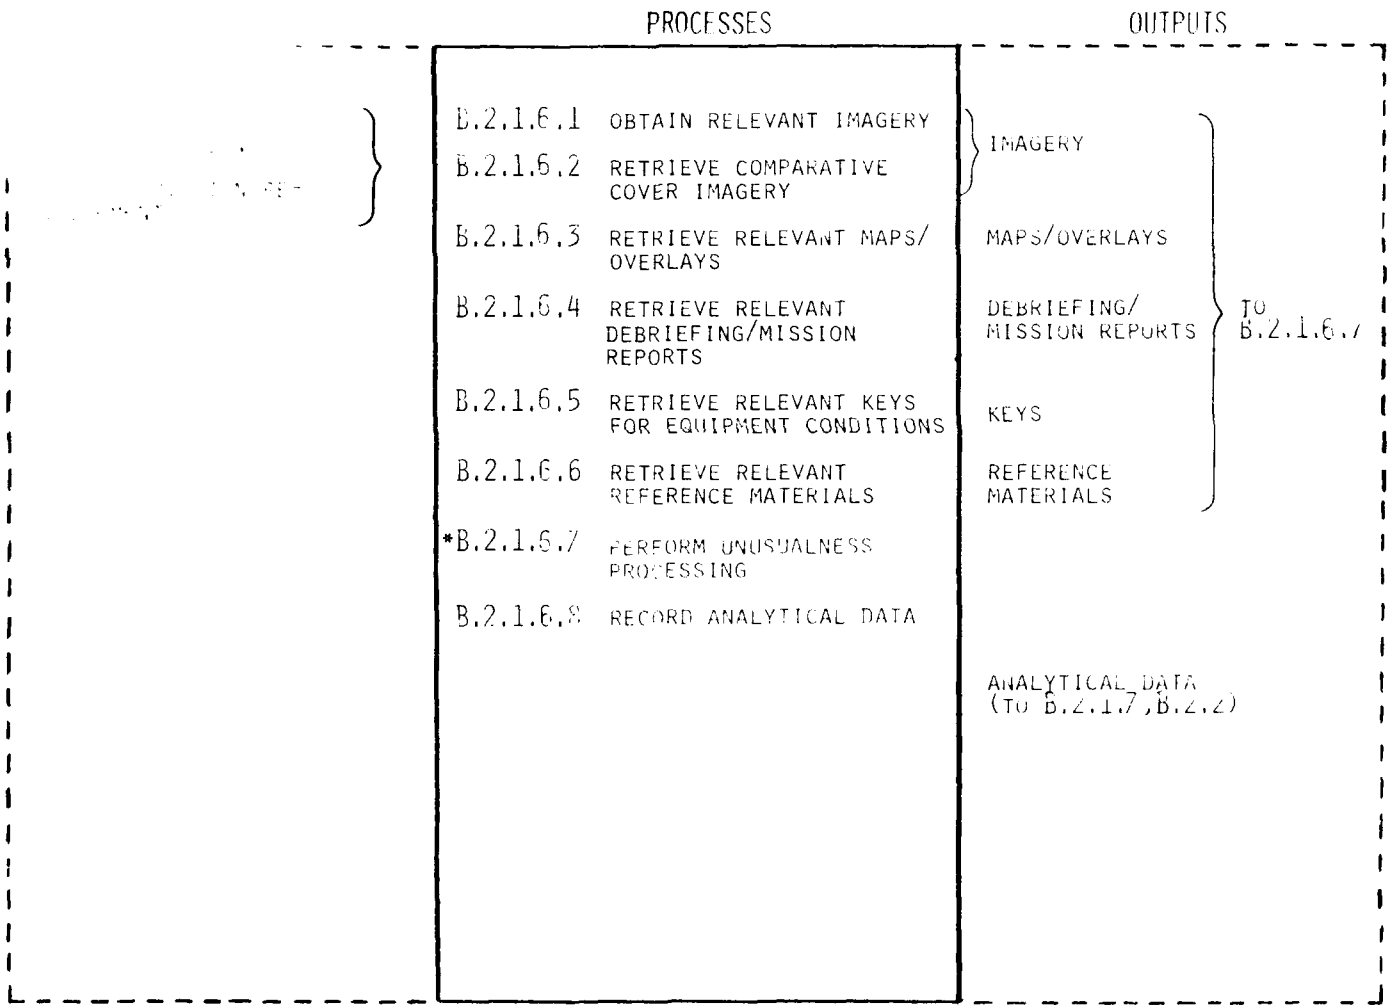
B.2.1.5 Target Quantification

The division between the target identification (B.2.1.4) and quantification activities on the one hand, and the quantification and photogrammetric (B.2.1.7) activities on the other is often blurred in a tactical field situation where a single individual performs all these functions with respect to a given target. Even on the level of strategic imagery interpretation resources, however, an estimate of the number of identified objects of a particular type will be recorded simultaneously with the identification data, although photogrammetry is usually handled by a separate, specialized, element.

An important difference exists between the rough counts made in the course of first phase interpretation for immediate detection of significant changes in the situation and the detailed counts made in later phases of interpretation to validate records of such changes. Detailed counts involve reference to all available data to determine, for example, where the missing aircraft from a group of 28 reported earlier might be (in hangars, on a reconnaissance mission, camouflaged, lost or destroyed, returned to base of origin).

Similarly, gross sizing estimates of reportable items ("slit trenches approximately 50 feet long and 4 feet deep") are usually recorded with location and identification data. However, where required by reason of potential significance, gross sizing estimates and associated imagery are input to the photogrammetric function for exact mensuration.

B.2.1.6 UNUSUALNESS ANALYSIS



* indicates expansion of function in following pages

B.2.1.6 Unusualness Analysis

An important activity of an IIA is alertness to unusual objects, previously unknown equipments or novel modifications of known equipments, numbers and concentrations of military objects or personnel, terrain modifications, dispositions of equipment, directions of movement, etc. Where the knowledge of the IIA is insufficient, it can be supplemented with analytical aids and reference materials, which, in the context of the experience and skills of the particular IIA, can assist in distinguishing unusual objects and patterns of activities from normal phenomena.

Like target detection (B.2.1.3), identification (B.2.1.4), and quantification (B.2.1.5), unusualness analysis may be driven by the general requirements of the given mission, EEI in effect at that time, and Standing Requirements List (SRL), or by a Specific Request for Information (SRI) of the type "Notify me if you see anything unusual in Sector x".

Although unusual objects or conditions may be noted in a first phase or preliminary screening interpretation process, unless such manifestations are fairly dramatic, it is more likely that unusualness will be perceived during a second or third phase interpretation activity, or will be resolved at that level. If a novel item of equipment appears on a tank, exact mensuration and special functional analysis of the part may be required in order to determine the significance of the new addition.

Unusual activities or objects may be tipped off or interpreted via all- source data channels. Messages and other all source reference materials are therefore critical inputs to the recognition and analysis of unusualness.

B.2.1.6.7 UNUSUALNESS PROCESSING

B.2.1.7 Function Analysis

In contrast to the previously described image interpretation process steps, analysis of the function of an object, equipment modification, or environment modification is mainly limited to third phase interpretation, where detailed analysis can be carried out without affecting time-critical deliveries of information.

Function analysis is especially important in image interpretation for support of basic intelligence production related to developments in foreign science and technology.

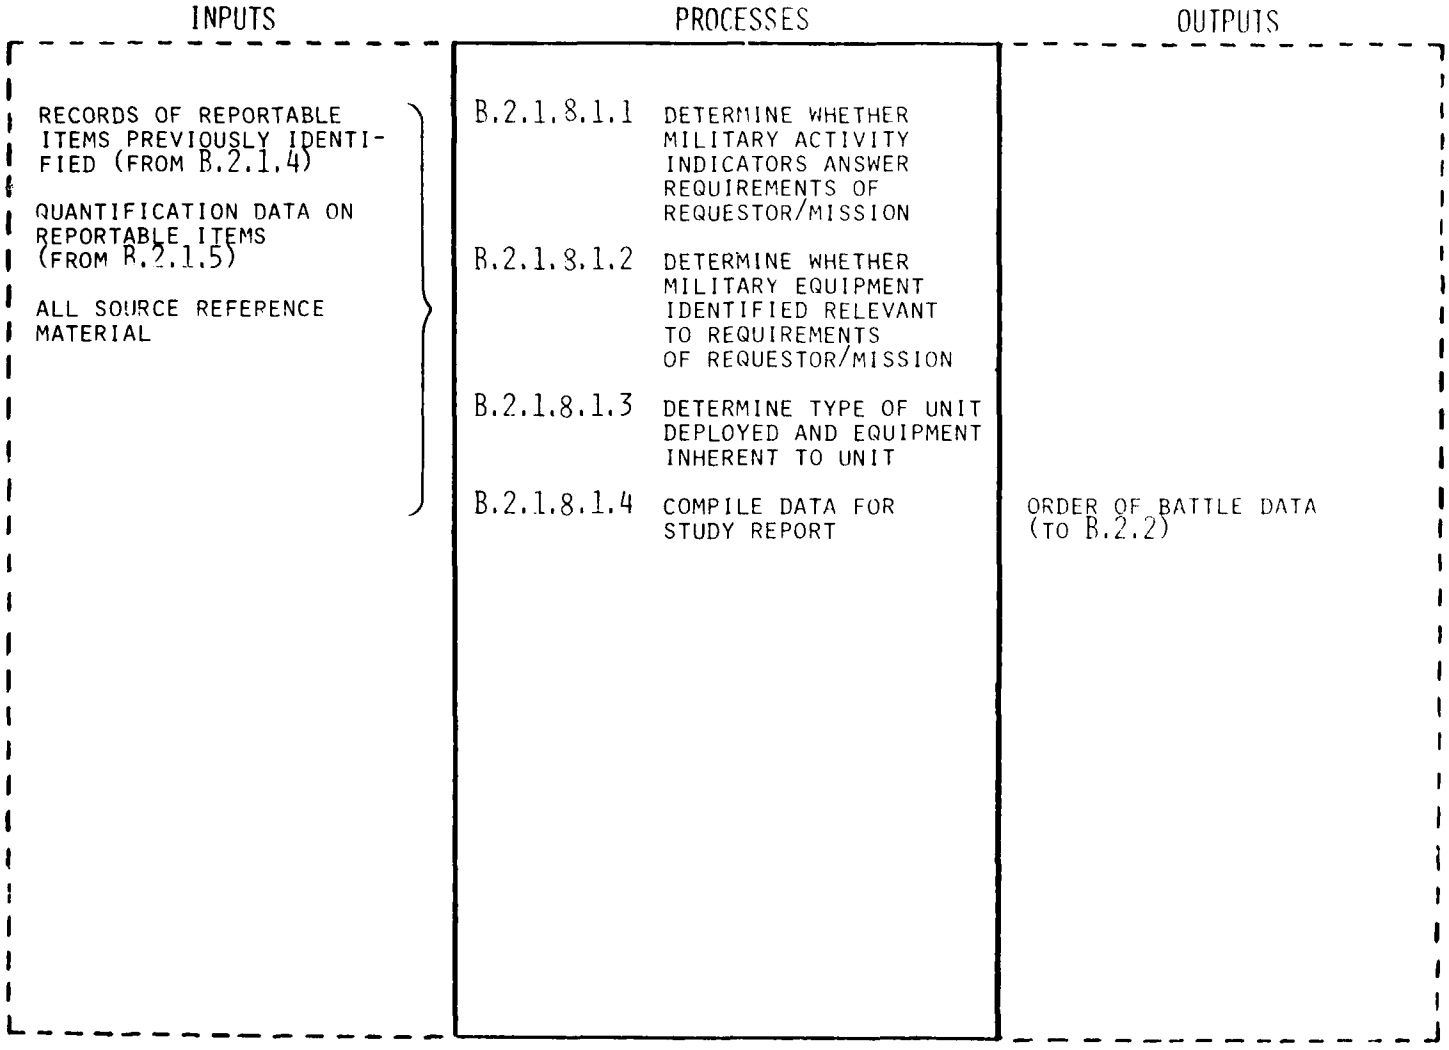
OTHER COMPLEX STUDIES

B.2.1.8 Complex Studies

The analytical work described under the topic of 'Complex Studies' is seen primarily as third phase, in-depth imagery interpretation activity, without the severe time constraints associated with first and second phase interpretation processes. Although some aspects of these topics may apply equally to first and second phase processing (for example, some Order of Battle analysis may in fact be carried out simultaneously with identification and quantification of objects of military significance (B.2.1.4., B.2.1.5)), the type of detailed analysis exemplified by these studies requires more processing time and the use of more reference materials than is possible in the preliminary scanning and continued processing phases.

The complex studies shown in the accompanying chart are intended as examples of the types of studies which are performed by IIAs at the tactical and strategic levels. The examples given are more typical of tactical level analytical activities. At the strategic level, detailed studies of weapon systems, missile and space technology, and other types of in-depth analytical studies involving imagery are performed.

B.2.1.8.1 ORDER OF BATTLE ANALYSIS



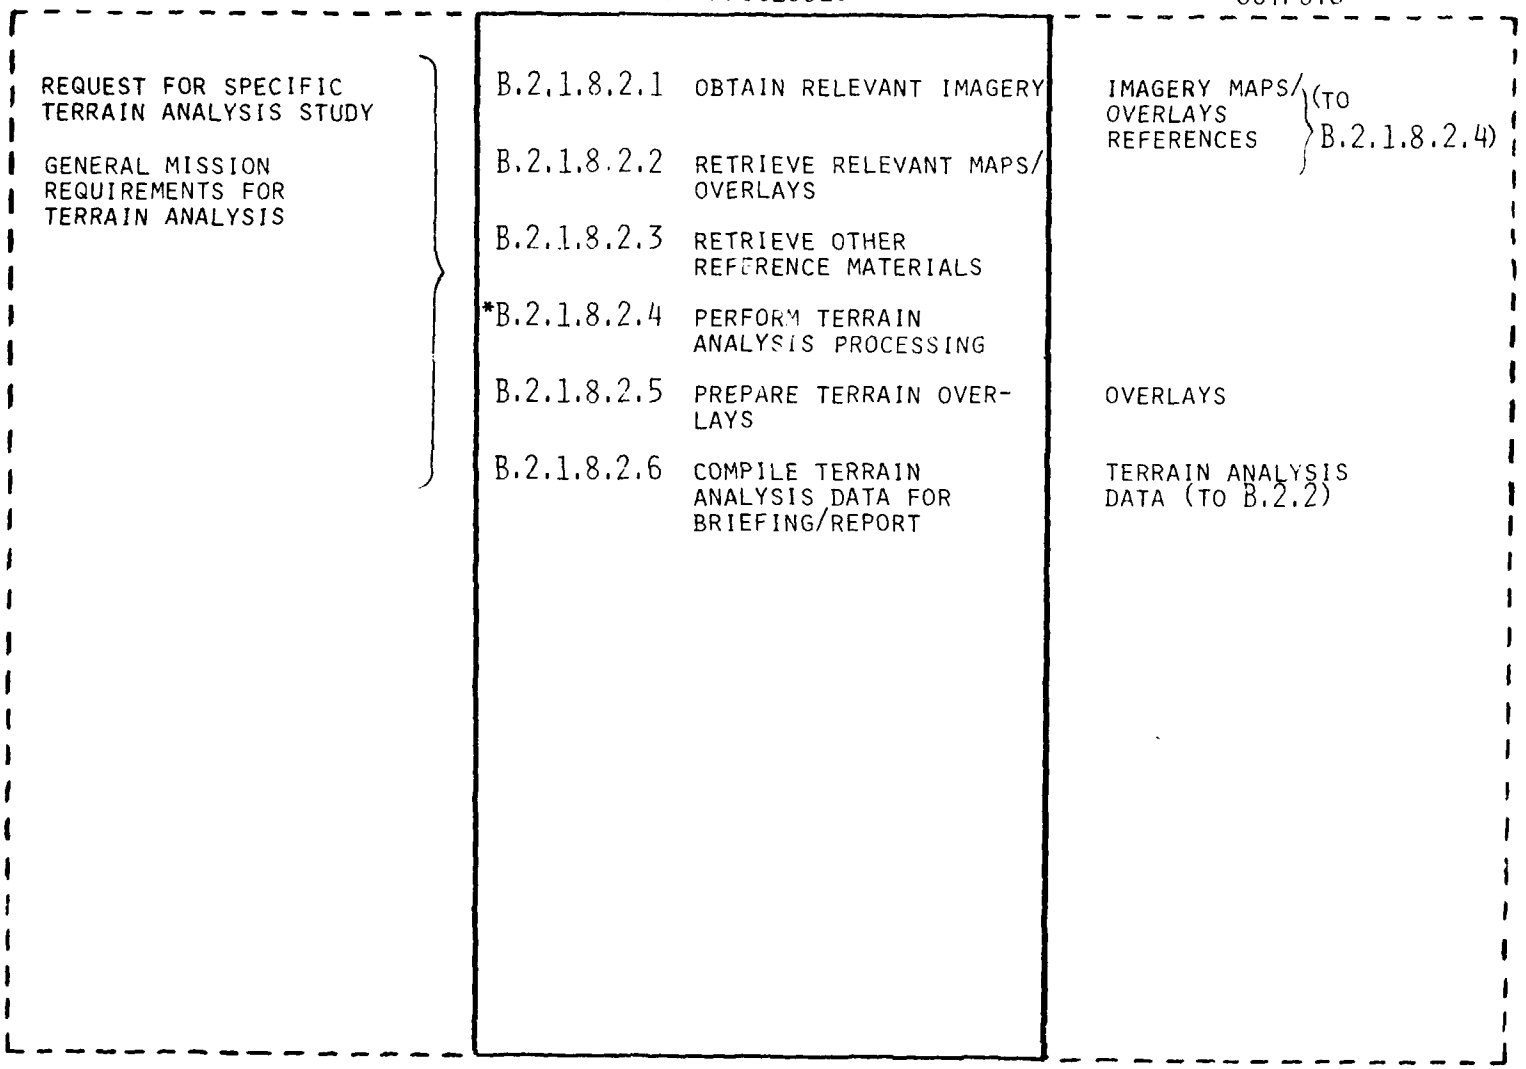
* indicates expansion of function in following pages

B.2.1.8.1 Order of Battle Analysis

Using identification and quantification data from the functions represented in B.2.1.4 and B.2.1.5, the image interpreter determines the significance of these data in terms of Order of Battle. In the identification and quantification processes, the image interpreter is concerned with what type of equipment is shown in the imagery, and how many of these equipments are represented. In Order of Battle analysis, he associates these equipments with particular elements, evaluates the significance of the movement and direction of the given units, and determines what impact these deployments have on the Order of Battle of non-friendly forces by comparing current with previously reported dispositions. For example, the image interpreter may determine that the 2 T-62s previously reported are subordinate to the 103rd Tank Battalion, that they are moving toward the forward area, and may represent the vanguard of the 39th Tank Division, indicating a replacement of the previously noted 42nd Tank Division in the forward area.

In order to perform this type of analysis, the image interpreter requires -- in addition to his usual maps, overlays, and reference material -- all source reference material, including all current message traffic relevant to his area of responsibility and hard copy reports containing Order of Battle data.

B.2.1.8.2 TERRAIN ANALYSIS



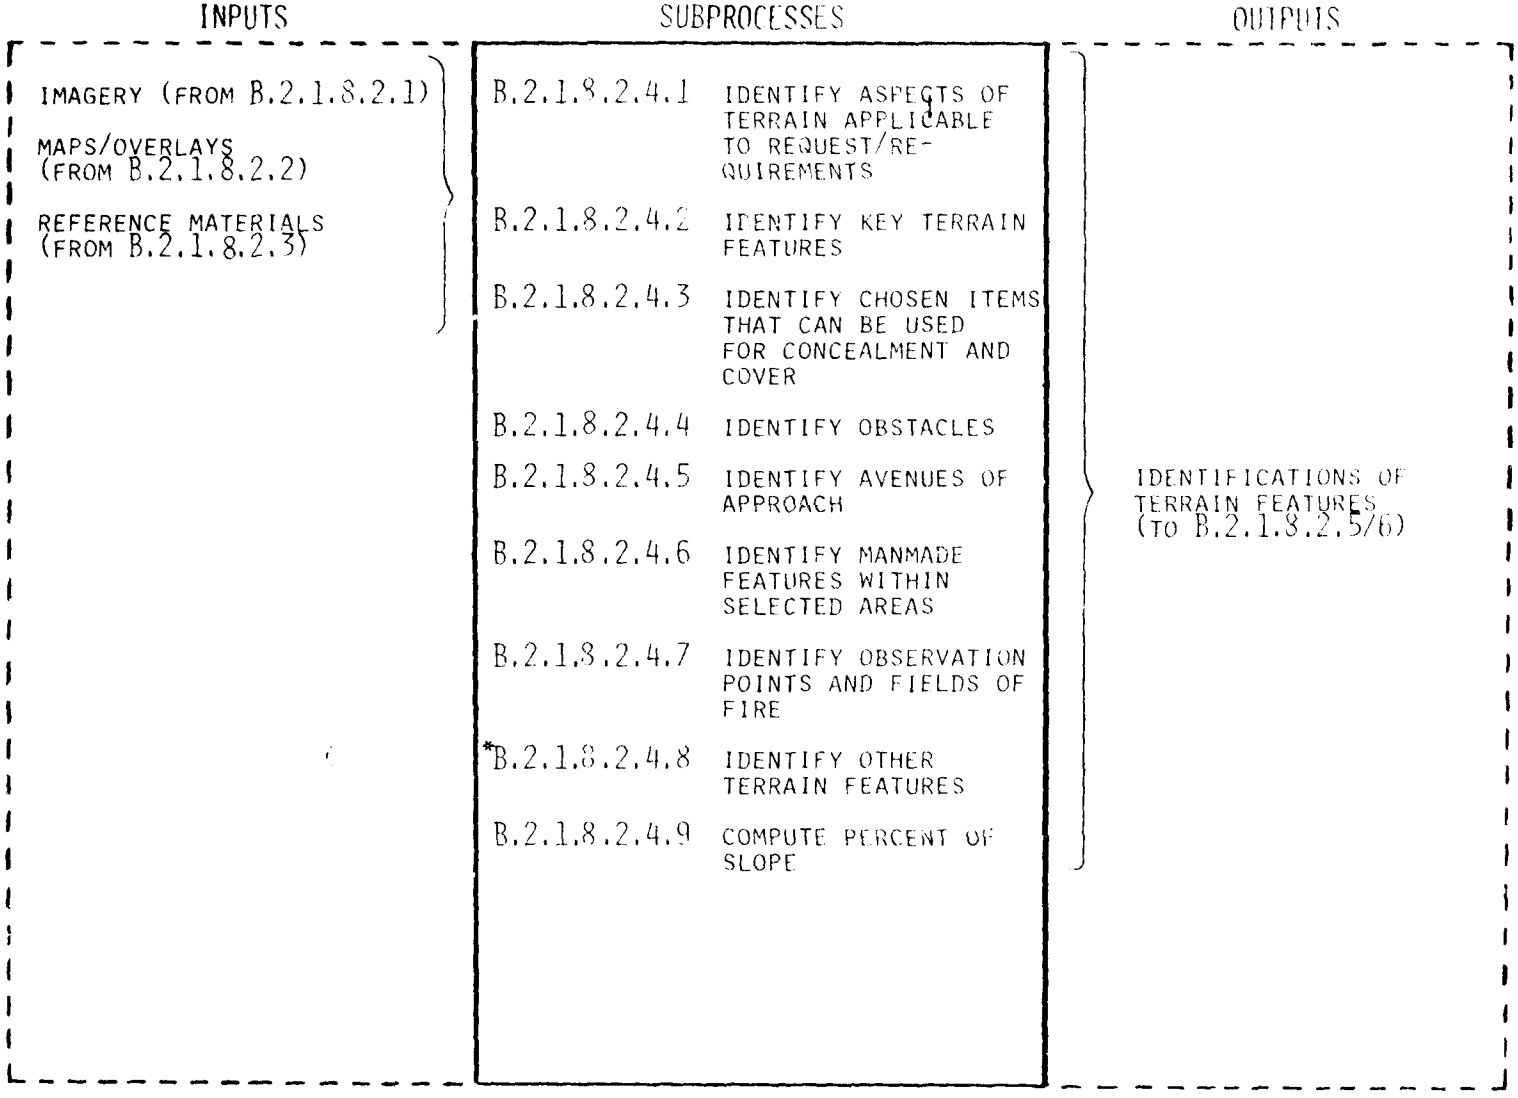
* indicates expansion of function in following pages

B.2.1.8.2 Terrain Analysis

Terrain analysis studies are generally carried in accordance with some mission-related requirement, although special requests for terrain analysis of particular areas may also occur. In addition to imagery, maps, and overlays, the image interpreter will use other types of reference material giving details of density of forestation, width of trees, specifics of natural obstacles such as rivers and canyons, specifics of urban areas such as width of streets, height of buildings, population of the area, and other data, as required.

The analytical data resulting from this process may be presented in the form of a briefing, with graphics and overlays; as terrain overlays or templates for SITMAPS; or in the form of a message or hardcopy report.

B.2.1.8.2.4 PERFORM TERRAIN ANALYSIS PROCESSING



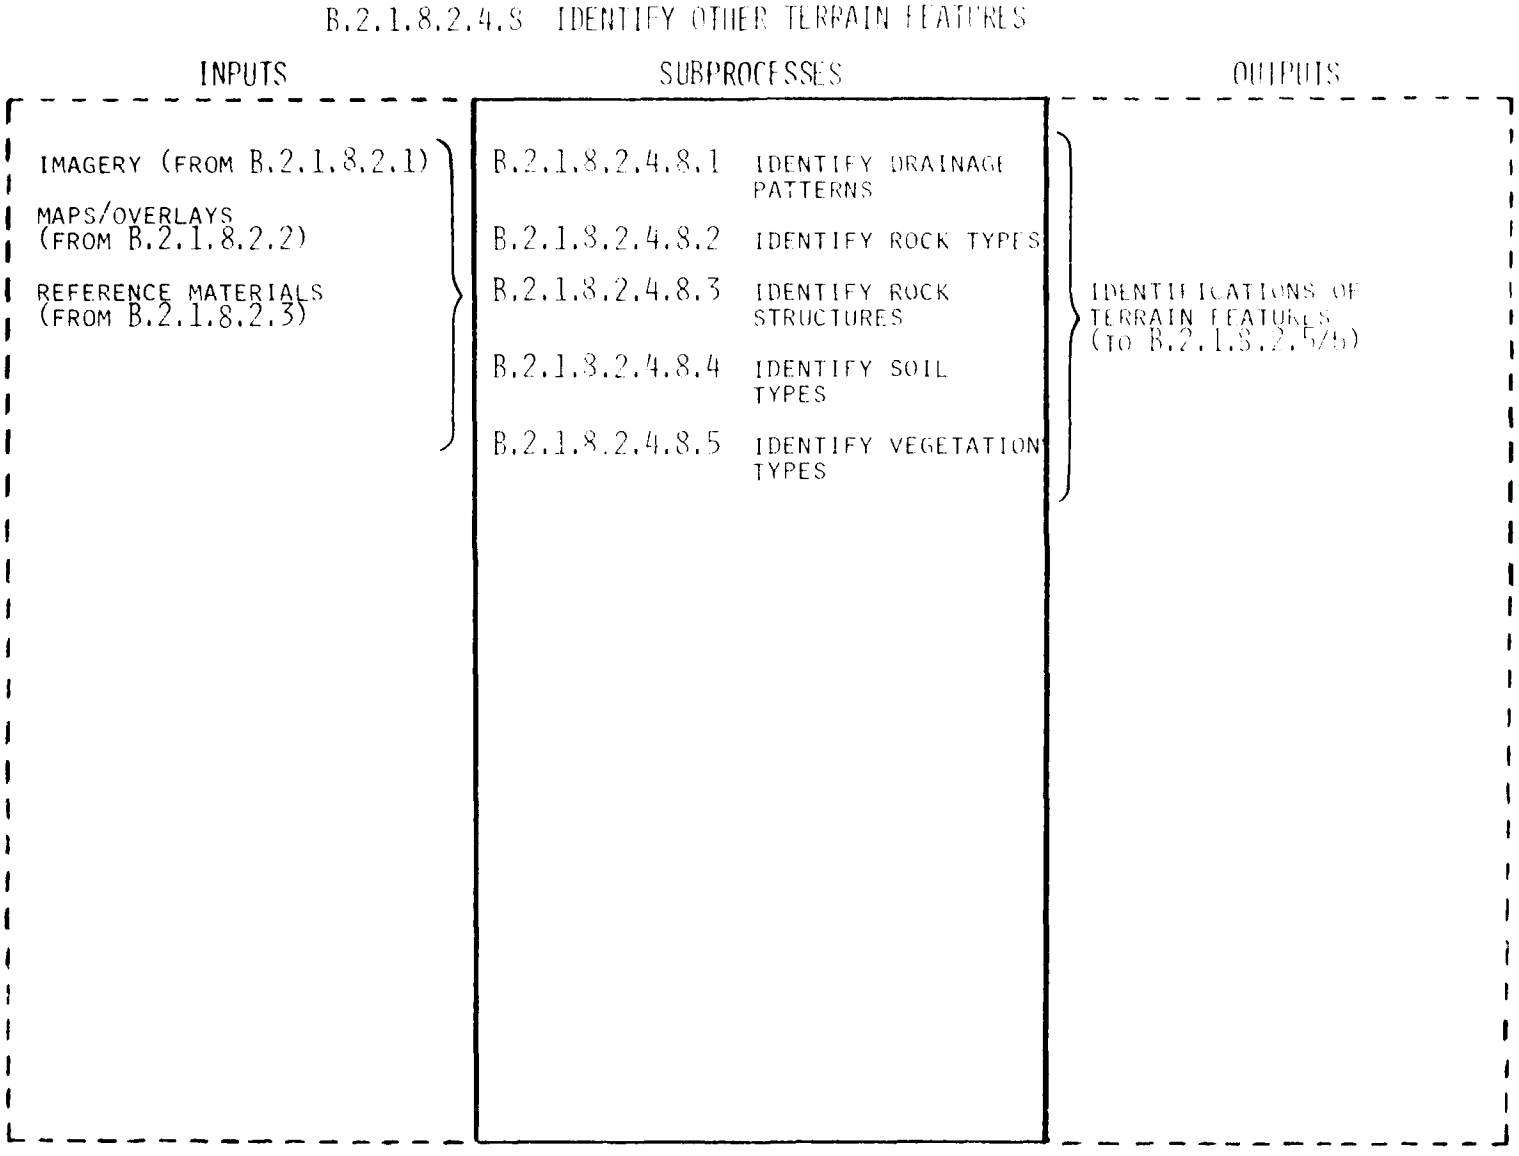
* indicates expansion of function in following pages

6.2.1.8.2.4 Perform Terrain Analysis Processing

In performing the terrain analysis subfunction, the image interpreter is first concerned with identifying key features of the terrain under investigation. For example, a particular hill mass in a given sector might provide an essential offensive or defensive advantage -hence possession of it is key to the friendly forces' position. Similarly, a particular bridge or river crossing (such as a fording area) may provide the unique means of controlling access to and egress from a given sector.

Terrain features which can be utilized for concealment and cover are of obvious importance in a tactical situation. To illustrate, a deciduous forest will normally carry a dense canopy of leaves during at least six months of the year, thus providing protection
providing good cover from ground fire and partial cover from aerial observation; however, a planted area such as an orchard would provide very minimal cover.

Natural obstacles would include such terrain features as rivers, dense forests, mountainous or steep hilly terrain, while avenues of approach are rolling or flat areas free from such obstacles. Man-made features include building construction (e.g., buildings with basements or underground areas provide cover from enemy fire), roads, bridges, railroads, airports, etc. Observation points may be manmade, such as a church steeple, or natural, such as an escarpment. Fields of fire may be defined in terms of proximity to a terrain feature providing a good defensive or offensive position, range in terms of line-of-sight firing, relationship of cultivated land to forested areas, and so forth.

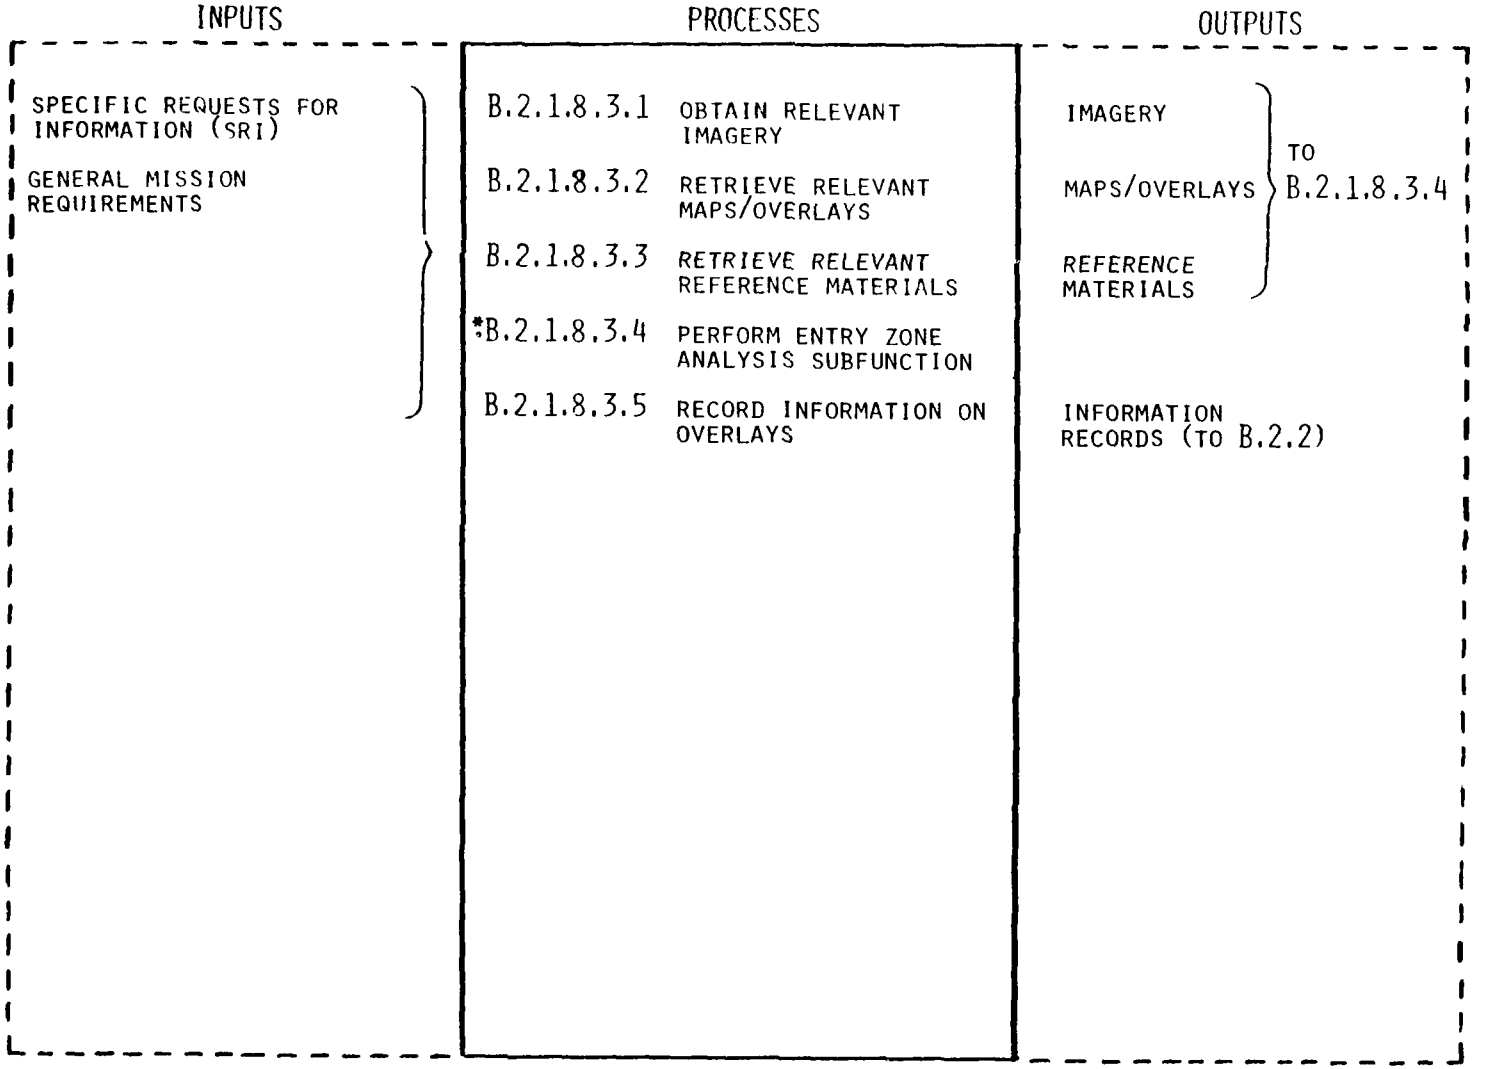


* indicates expansion of function in following pages

B.2.1.8.2.4.8 Identify Other Terrain Features

In addition to the more specific delineation of terrain features in terms of tactical significance, general features of the given area are also important to analyze. Knowledge of drainage patterns is critical to evaluating trafficability of roads and low-lying areas in wet seasons, information on rock types and surface materials is required for evaluating whether off-road areas can support armored vehicles and other heavy military traffic, or whether rock structures can serve as gun emplacements, etc. Information on vegetation types is also important in a tactical situation, since -- for example -- a coniferous forest is generally far more open than a deciduous forest, having less underbrush to impede movement of troops, and offering less potential for concealment from ground fire.

B.2.1.8.3 ENTRY ZONE ANALYSIS

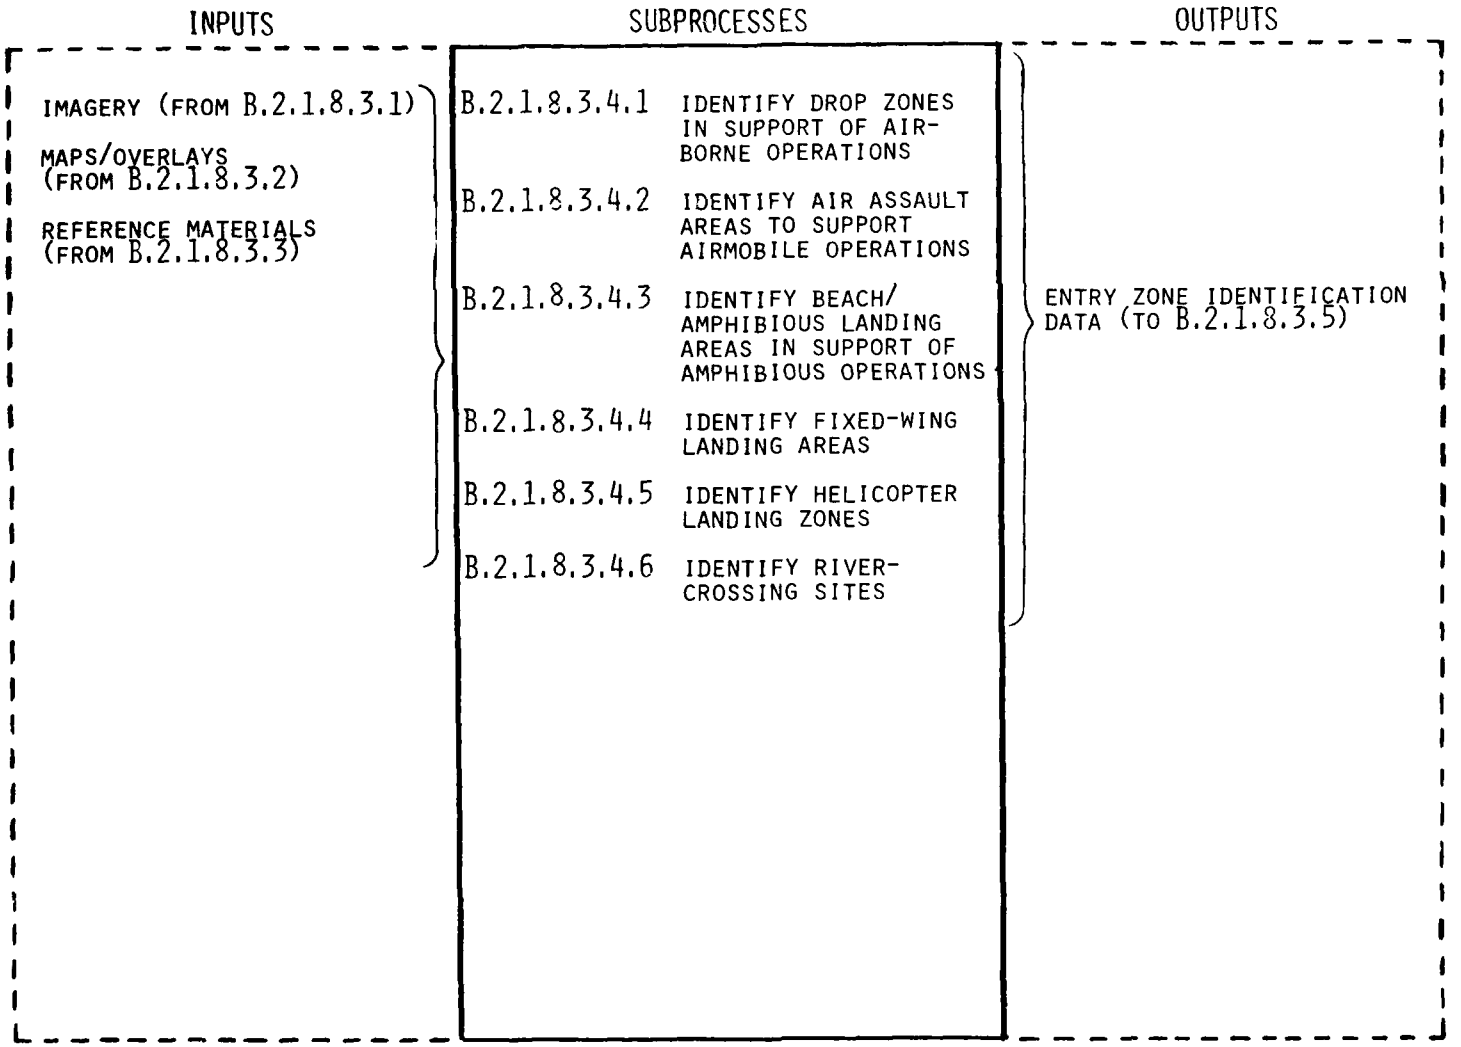


* indicates expansion of function in following pages

B.2.1.8.3 Entry Zone Analysis

Another important activity in tactical imagery interpretation is analysis of potential zones for introducing assault troops into forward areas, which may be unoccupied, or held by non-friendly forces. In the latter case, materials utilized as background for the analytical study include all source message traffic and hard copy reports as well as the imagery, maps, and other reference materials indicated in the associated chart. Potential zones that are identified by the IIA tasked with the analytical study are indicated on overlays to assist in assault planning based on a SITMAP, or other map of the given area.

B.2.1.8.3.4 PERFORM ENTRY ZONE ANALYSIS PROCESSING

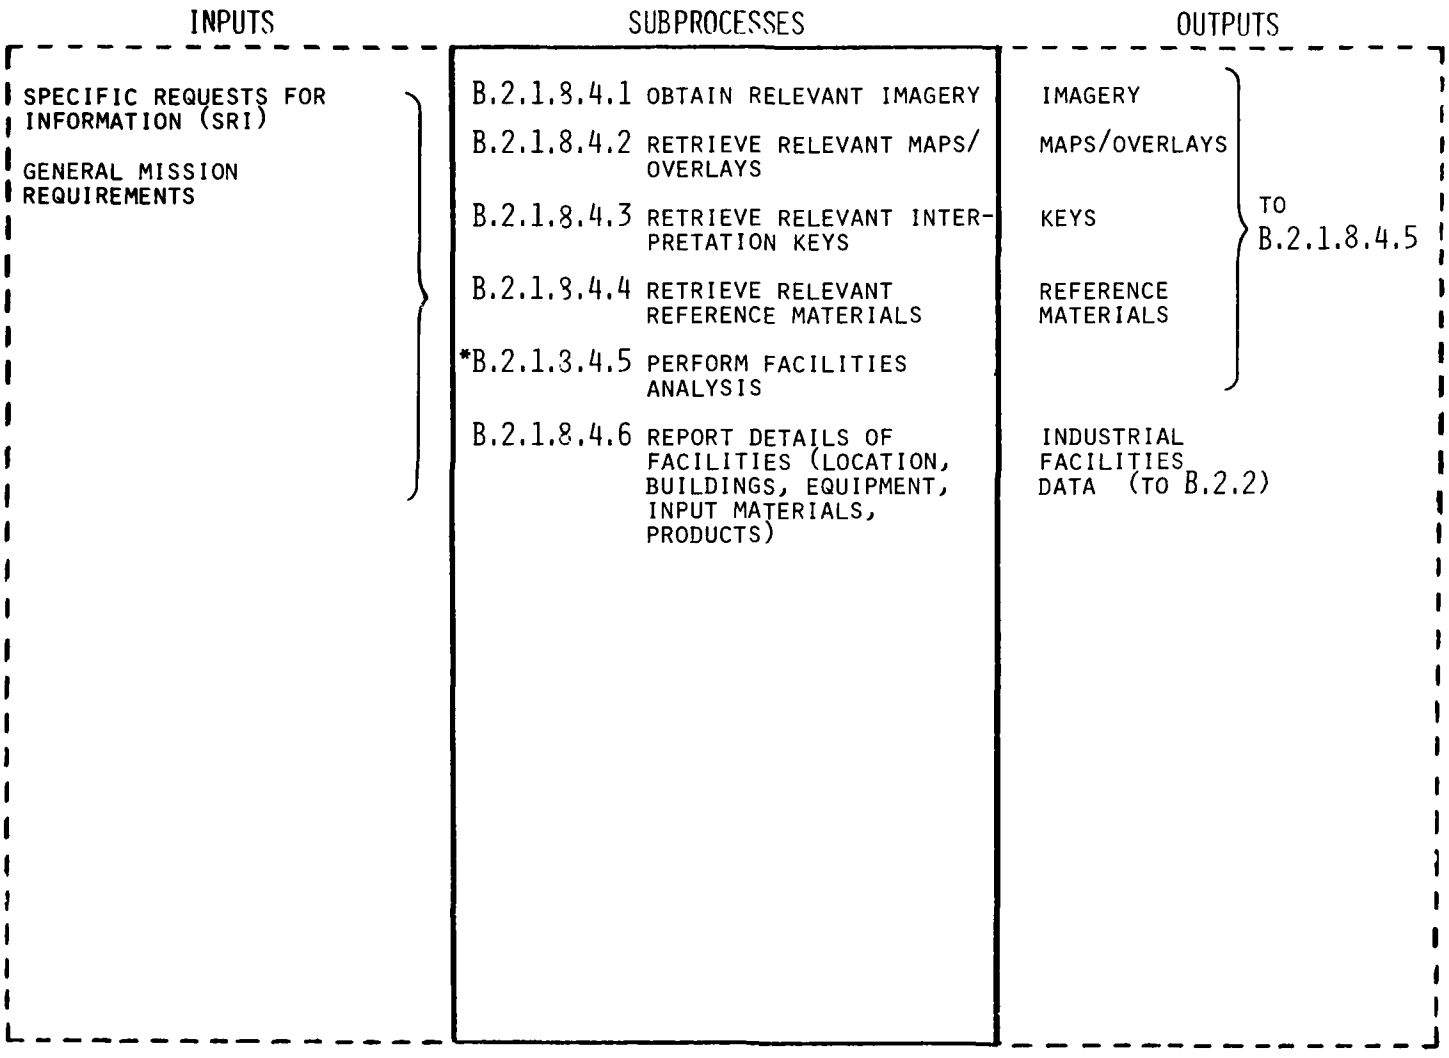


* indicates expansion of function in following pages

B.2.1.8.3.4 Perform Entry Zone Analysis Process

The entry zone identification process covers a range of potential means of entry and offers alternate zones where possible. The analytical process thus includes identification of potential drop zones for possible airborne operations, air assault areas in support of airmobile operations, beach and amphibious landing areas for amphibious operations, fixed-wing and helicopter aircraft landing areas, and potential river crossings.

B.2.1.8.4 INDUSTRIAL FACILITIES ANALYSIS



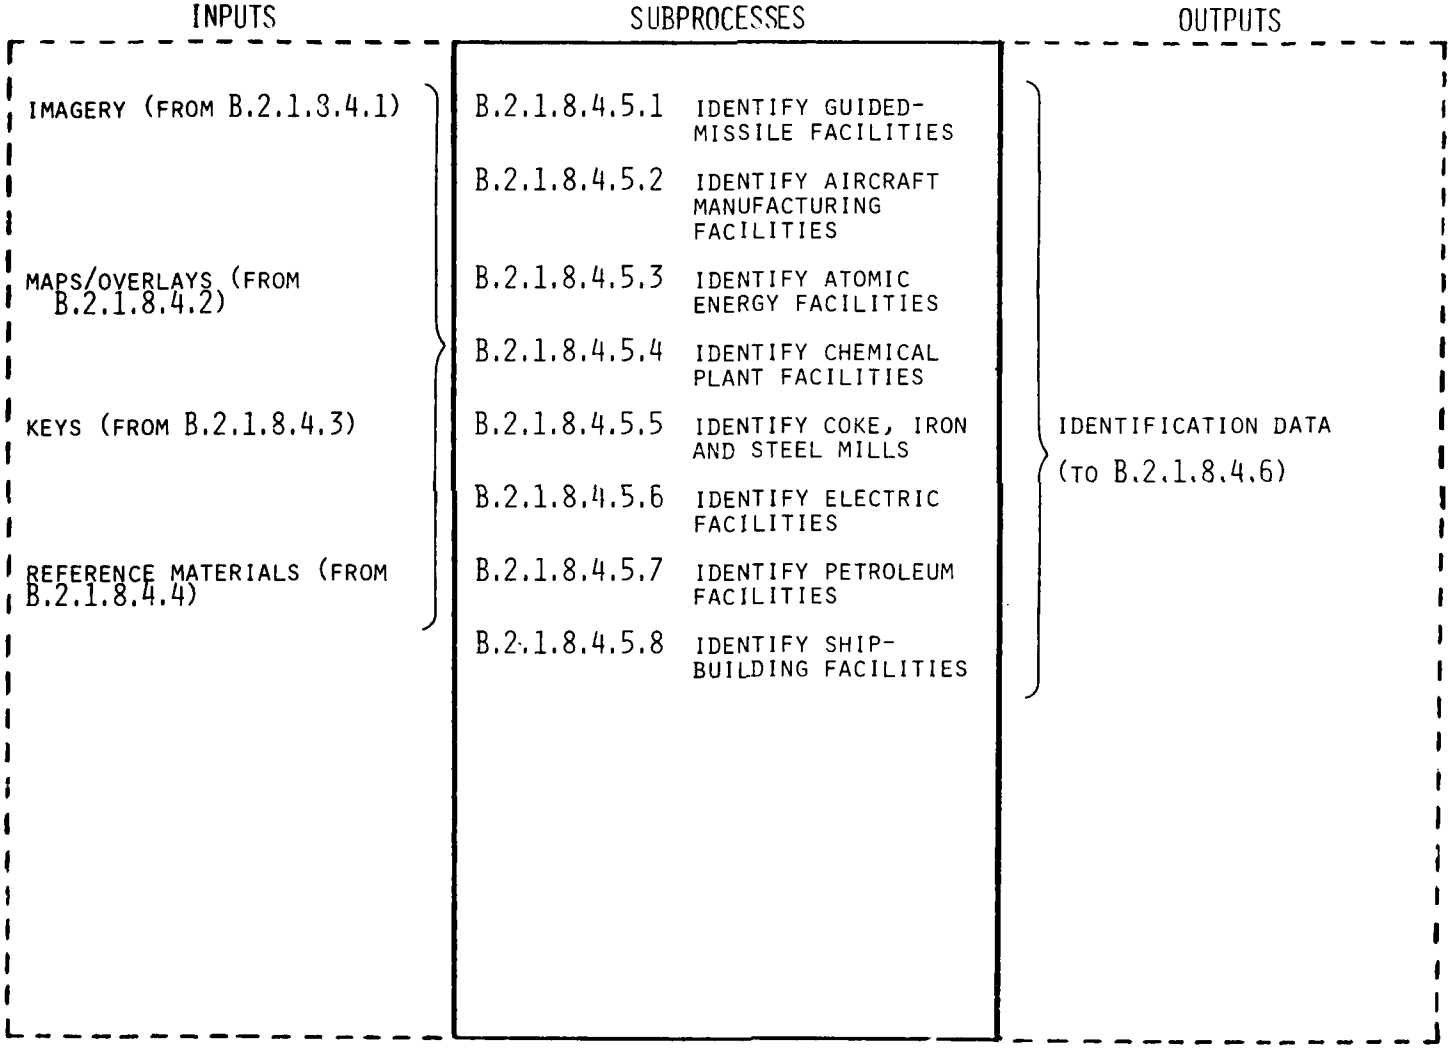
* indicates expansion of function in following pages

B.2.1.8.4 Industrial Facilities Analysis

At the national level, studies of strategic industrial targets are an important responsibility for continuing evaluation (e.g., analysis of new construction, changes in input materials or output products, changes in flow of materials among the various components of an industrial complex). Industrial facilities directly involved in the production of military equipment such as tanks, guns, or missiles are of special interest, with respect to information that may be gleaned concerning modifications or product developments.

In a tactical environment, industrial facilities may also be assigned for special study, if they are present in the area of operations, or are involved in support of military organizations operating in the area.

B.2.1.8.4.5 PERFORM INDUSTRIAL FACILITIES ANALYSIS

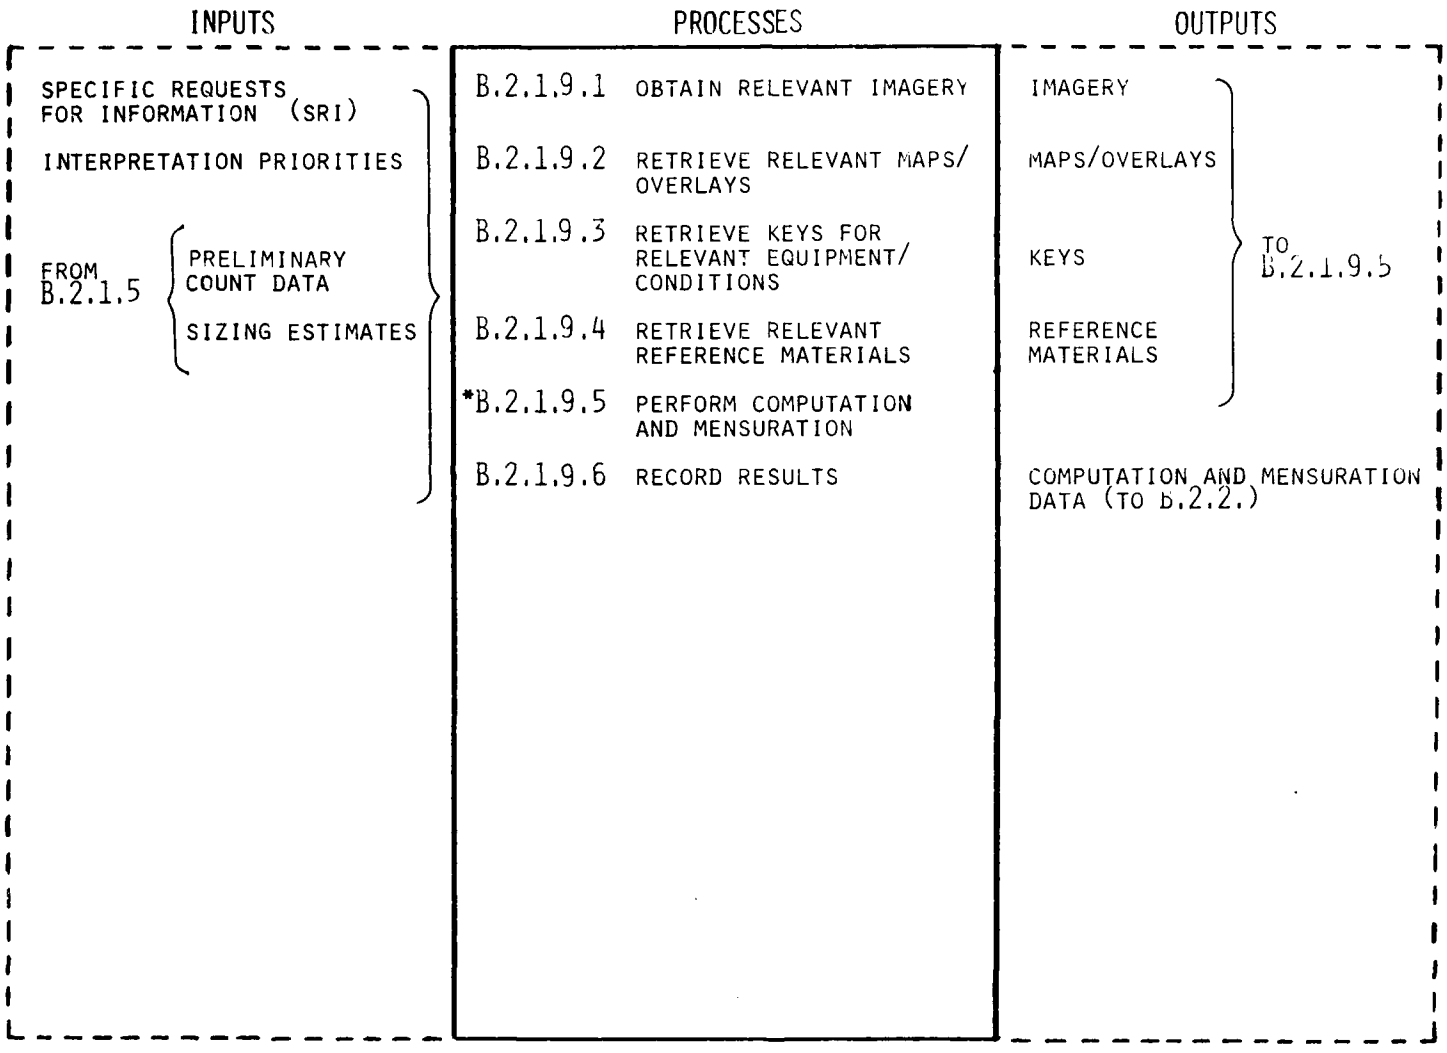


* indicates expansion of function in following pages

B.2.1.8.4.5 Perform Industrial Facilities Analysis

In analyzing industrial facilities for a detailed study, the IIAs charged with the study task must perform an identification and analysis in sufficient detail to provide a complete description of the given facilities (in terms of available imagery and reference materials). Such a description should include the specific location and layout of all buildings belonging to the industrial complex, all related equipment, input materials, output products, and insofar as possible, the flow of such materials and products within the complex.

B.2.1.9 PHOTOGRAMMETRIC SCIENCES



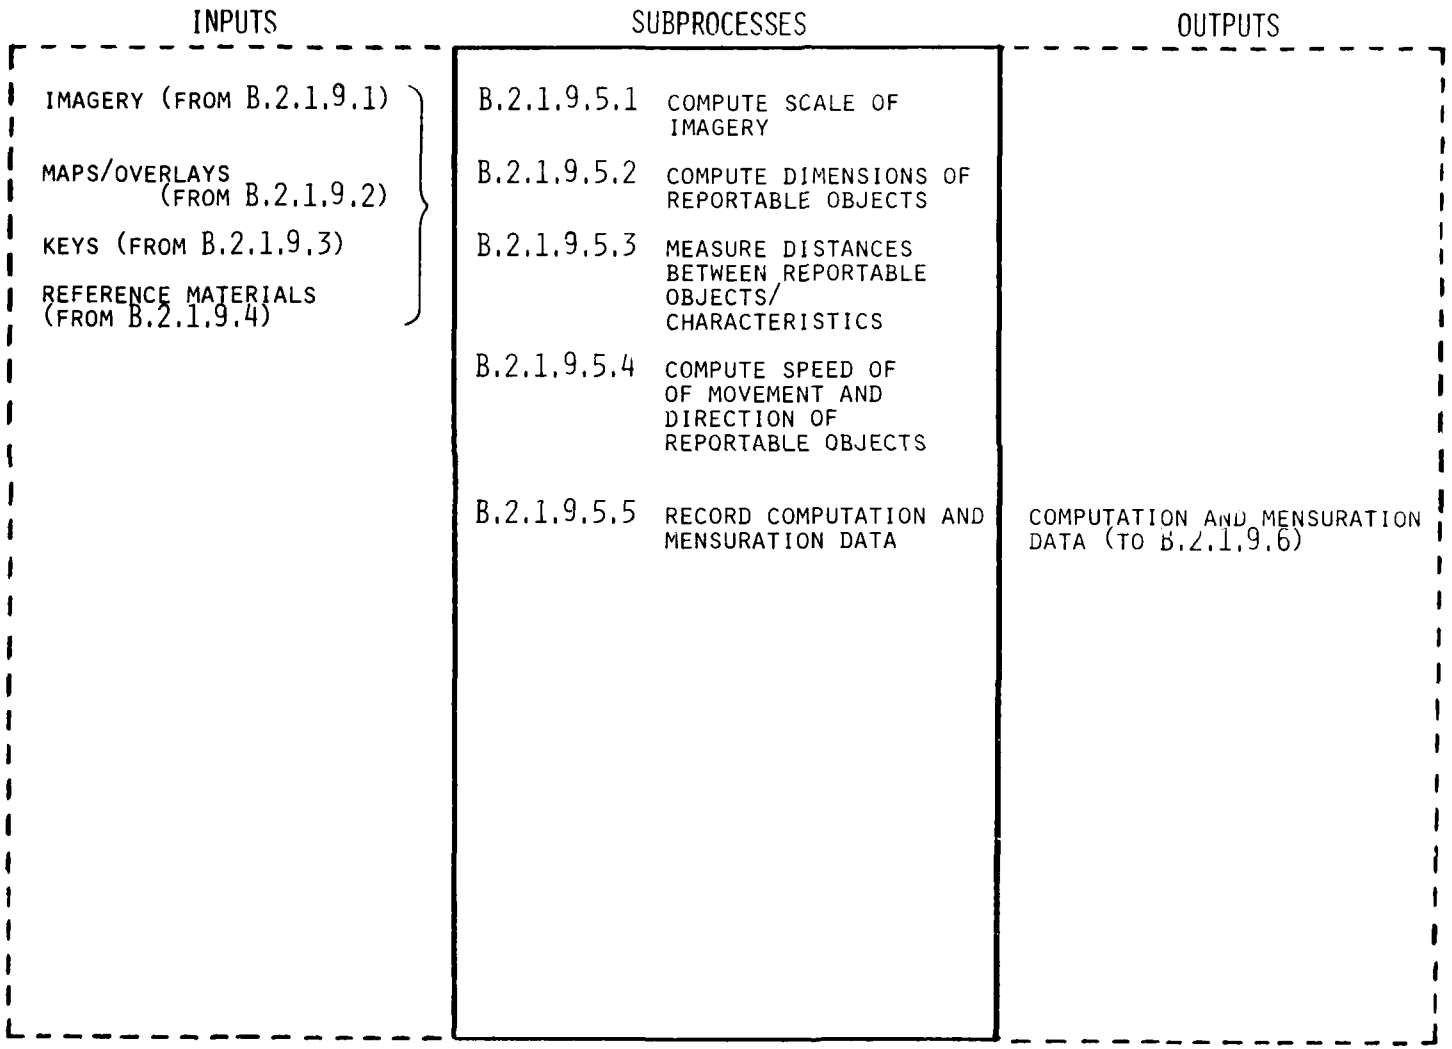
* indicates expansion of function in following pages

B.2.1.9 Photogrammetric Sciences

The photogrammetric activity includes all detailed mensuration and computation which is required in imagery interpretation. At the lower level tactical facilities, an IIa may carry out his own complex mensuration and computation activities. On the other hand, at higher level tactical facilities and at the national resource level, photogrammetry tends to be a specialized function supported by a group of image interpreters with extensive experience in computation and mensuration, who are solely involved in photogrammetric processing.

Inputs to the photogrammetric process are mainly driven by Specific Requests for Information (SRI) in the sense that the mission of the photogrammetric specialists is to respond to such requests from the non-specialist image interpreters supported by the particular photogrammetric element. Preliminary count data and sizing estimates may provide data for validation, or in cases where there is no specialized photogrammetry support, a basis for detailed computation and mensuration.

B.2.1.9.5 PERFORM COMPUTATION AND MENSURATION

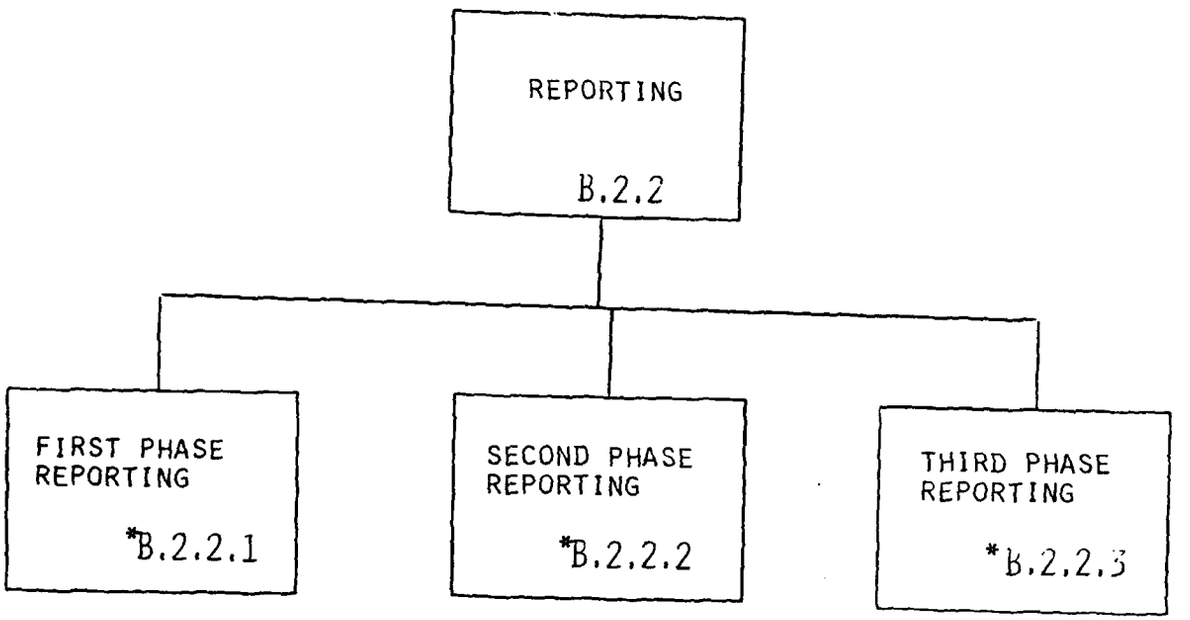


* indicates expansion of function in following pages

B.2.1.9.5 Perform Computation and Mensuration

The most basic photogrammetric task is that of computing the scale of the imagery involved in analysis. Although most scale computation on the national level is precalculated, because the collection effort is planned far in advance, this is an important task on the tactical level. IIAs in the tactical environment are trained to compute scale using focal length of the camera and altitude of the aircraft. If these are not available, the IIA uses computations involving determination of scale in terms of the largest and best defined scale indicator on the imagery, where photo distance and ground distance are established in terms of this indicator. More complex methods of scale determination are required when the imagery is produced by oblique or panoramic cameras.

In computing the dimensions of objects appearing on the imagery, the IIA may choose the relief displacement method (where an object with a visible base is involved), or the shadow proportion method, where film taken in full sun is available.



*INDICATES EXPANSION OF DETAIL IN FOLLOWING PAGES

B.2.2 Reporting

Reports are the primary product of the image interpretation facility. The content of reports and the procedures for generating reports are nearly always dependent upon the amount of time available to produce the report. Because of the time factor in report generation, both at the strategic and tactical level reporting tends to fall into one of the three phases defined in Section 2.:

First phase reporting: preliminary scan on receipt of imagery. (This category also includes real time processing of SLAR, IR, and video imagery.)

Second phase reporting: within 24 hours of receipt of imagery;

Third phase reporting: longer than 24 hours, and periodic reporting.

The time boundaries of these phases as indicated above are only intended to be suggestive, since actual time periods differ slightly between the national strategic IMINT resources and tactical and II organizations, and are also affected by production load and priority. From this point of intelligence utilization of these phases generally corresponds to Indications and Warnings (I&W), Current Intelligence, and Basic Intelligence, respectively. Handling time is a major factor in determining the pace of analysis and reporting. Film development time, duplication of positives, and hardcopy distribution times are significant factors in determining minimum times for reporting imagery interpretation production results.

Because there is less time to analyze imagery in First and Second Phase processes, the detail and accuracy of reports is affected.

A first phase report might identify detected trends simply as light, medium, or heavy; whereas, a second phase report would also provide type identification and unit subordination.

With the increased time available for analysis, in second and third phase reporting the target information carried in the report can become more detailed but the potential for exploiting the target information for tactical or warning purposes decreases. Distribution lists for reports generally reflect the different uses of II reports from first, second, or third phase analysis.

Imagery interpretation reports are composed of the following elements which are relevant to the IMINT products:

Source identification

- Facility
- Time of preparation
- Analyst

Mission

- Mission ID
- Time
- Frame reference
- Sensor parameters
- Location parameters

Requirement reference

- Agency
- Desk
- Requirement number (or message reference)
- Priority

Classification

Content codes report priority Imagery Interpretation Text
Graphics (optional)
Imagery copy (optional)
Target Description

All-source material references (optional)

Imagery quality rating

NIIRS
Previous report references (optional)
Follow-up information (optional)

Release authority

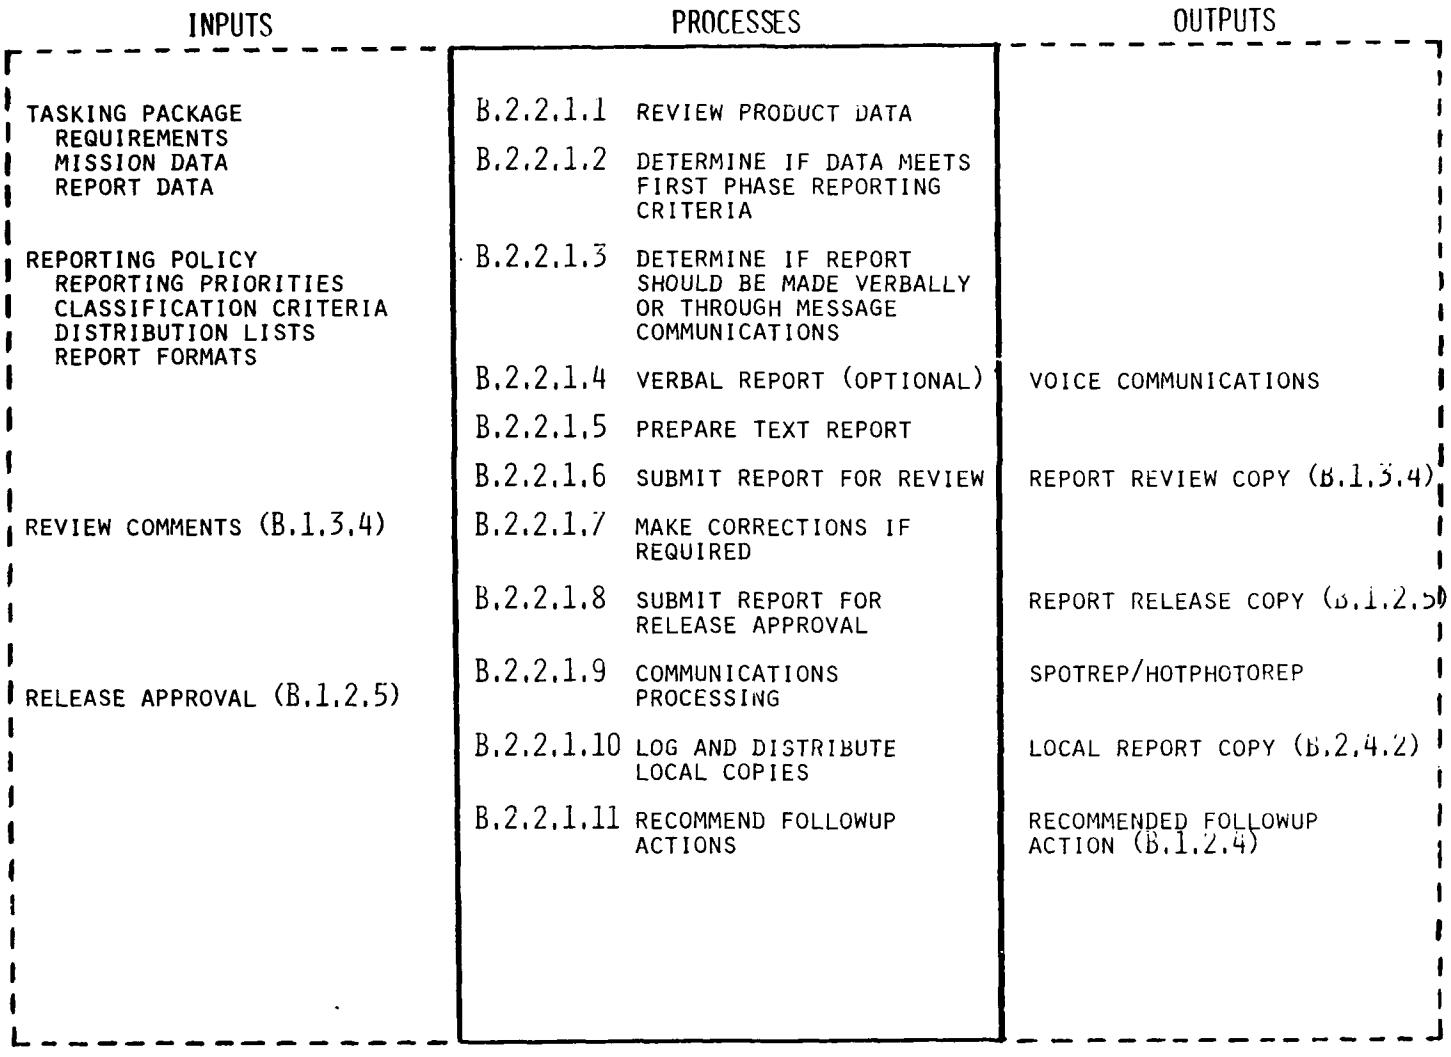
Report reference

The imagery interpretation report as an information entity can be viewed from the perspective of the mission, the target, the tactical or strategic threat significance, security, classification, and communications. These different perspectives are the framework within which sets of messages are dealt with in various stages of production. These perspectives are highly significant to analysis of the information structure and data base requirements of the II facility.

B.2.2.1 FIRST PHASE REPORTING



* indicates expansion of function in following pages

B.2.2.1 First Phase Reporting

First phase reporting supports strategic Indications and Warning and current operations at the tactical level. First phase processing activities include target detection, target identification, target quantification, and unusualness analysis. These activities are scheduled with the time frame of First Phase analysis but may not result in a First Phase report unless the results meet First Phase reporting criteria.

Second and Third Phase imagery interpretation processes might result in a First Phase type of reporting if the results are of immediate intelligence significance.

Several types of reports are normally associated with First Phase reporting. Voice reports through secure communications networks are the most direct means of reporting significant items. This reporting mode is particularly effective in the tactical environment when IR or SLAR imagery interpretation is being used to exploit detection of moving targets. Verbal reports are sufficient only if the requirement is limited to a single user. Items of general interest must be recorded and reported in textual form. SPOTREPORT is a term normally associated with an in-flight intelligence report. HOTPHOTOREP is a term associated with reports resulting from the first scan of a wet or dry negative film at the completion of a mission.

First Phase interpretation products may be used to guide followup tasking in subsequent interpretation processing.

* indicates expansion of function in following pages

B.2.2.2 Second Phase Reporting

Second Phase reporting would nominally occur within 24 hours after receipt of imagery. A 24-hour cycle is consistent with mission scheduling during daylight hours and exploiting of Second Phase production products for current operations planning in the tactical environment.

Individual products or responses to specific requests for image interpretation products may be produced much sooner and reported when available. Other products may be delayed by workload and preemption by higher priority tasks.

Second Phase reports generally are transmitted as messages but may have accompanying photographs or graphics. Verbal reports may be used to satisfy special requirements with limited distribution. Data produced by Second Phase processing generally has a wide distribution through message communication networks. Not all users are interested in the same level of detail, so the II facility generally sorts reporting items by significance for immediate reporting, daily reporting, weekly reporting, highlighting, or summary type reports. Sorting of reportable products for these types of reports may be done on the basis of mission, geographic area, target type, or other predetermined criteria.

Since Second Phase interpretation products may be accumulated, summarized, and extracted from at the reporting stage, there must be a means of temporarily holding product data. This is normally accomplished through transfer of target folders or tasking packages which contain requirements, mission data, processing results, and appropriate enclosures. Automated data processing

systems have been utilized within the larger national level facilities to manage the requirements, tasking, mission, and text reports produced during Second Phase processing. Report preparation is likely to be done by a person other than the II analyst that performed the analysis.

Typical reporting forms for Second Phase products are:

IPIR Immediate Photo Interpretation Report

SUPIR Supplemental Photo Interpretation Report

GPIR General Photo Interpretation Report

MIPIR Machine IPIR (Computer-generated report)

MISREP Mission Report

All but the MISREP generally follow the same standardized Military Message Format. The MISREP is limited to tactical environments and includes a summary of all pertinent flight parameters, sensor parameters, aircrew observations, and summary of imagery interpretation results.

B.2.2.3 THIRD PHASE REPORTING AND PRODUCT OUTPUT

B.2.2.3 Third Phase Reporting and Products

The greatest diversity in reporting forms occurs in Third Phase II processing. Responses to tasking can be anything from a yes/no answer to a detailed document with enclosed graphics and photocopies Distribution of products may be highly selective and directed on an analyst to analyst basis. If the product is basic intelligence the report may be published as general intelligence information and receive wide distribution.

The suspense time for producing Third Phase reports may range from several days to periodic updates of basic intelligence spanning several years. Third Phase processing requires much greater use of collateral and all-source intelligence materials. All forms of imagery are exploited, and utilization of technical exchanges between intelligence analysts in different fields is possible because of the extended time available for analysis.

Information sources and reporting channels tend to be informal as well as formal. Third Phase imagery interpretation introduces a wider range of products besides written reports including:

Direct Support Imagery Interpretation Reports (DSIIR)

Basic Imagery Interpretation Reports

briefings

imagery interpretation keys

target identification posters

mosaics

II facility production planning documents

The division of labor for Third Phase processing activities follows specialty lines including the area of product preparation. Specialized support is provided for graphics and photocopies which are used extensively for Third Phase products.

One of the products of Third Phase processing is the technology to sustain the capabilities of the overall imagery interpretation mission. Imagery interpretation keys, updates to operating procedures, technical exchange between analysts, and individual skill and knowledge base development are products that aid in adapting to new requirements and improving current capabilities.

B.2.3.1.5

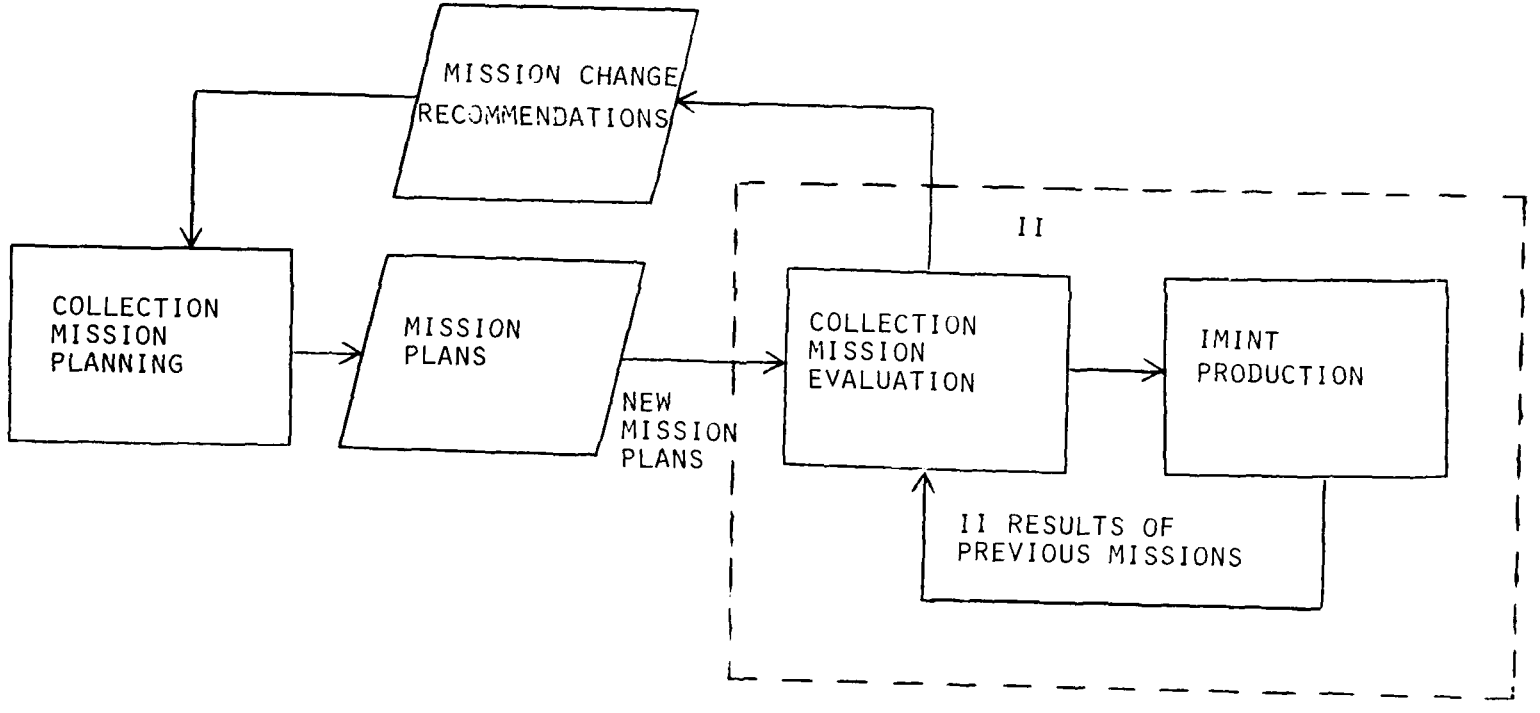
B.2.3.1 Collection Coordination

From the perspective of the IMINT production model, exploitation of collection capabilities is more of a concern than the control of collection itself. The II facility does not control collection operations or assign collection missions. However, the II facility exerts a high degree of influence on the planning of imagery collection missions through information which helps maximize the exploitation of imagery intelligence. This influence is exerted through a feedback mechanism in which the II facility manager informs the mission planner of his ability to meet production requirements with the planned collection missions. Mission planning is nearly always a limited resource problem, where an attempt is made to achieve maximum intelligence value. The feedback from the II facility to the imagery collection mission planner influences the selection of type of coverage, frequency of coverage, and priority of mission. Evaluation of previous mission results may be brought into the mission planning process where weather conditions inhibit interpretation or unusual activity is detected.

The importance of collection coordination in the imagery interpretation production model hinges on the flow of mission planning information to the II facility and the feedback of mission evaluations and recommendations to the collection planner. The benefits of this information exchange are greatest when the imagery collection missions are controlled in near real time.

As in any feedback control system, responsiveness is constrained by the delay in the feedback loop. Since the II analyst is the critical component in this loop, faster feedback can be achieved when the II analyst has an awareness of planned missions. II analysts interviewed were able to cite instances where they were able to coordinate changes in new missions in order to exploit results of newly processed imagery or adapt missions to new requirements. Filtering of information through chain of command has a dampening effect on this feedback mechanism. However, the time delay due to chain-of-command filtering can be minimized if collection coordination is implemented as a monitoring and technical exchange function and not as a formal interface.

B.2.3.1 COLLECTION MISSION COORDINATION



The particular communication channel used for coordinating collection missions depends on the collection system used and the controlling agency. Typically this communication channel is from the IMINT production manager to a liaison officer within the mission planning group. For strategic missions, an Army IMINT production facility has representation via OACSI on national level tasking committees and liaison with all U. S. intelligence agencies. In support of a theater of operations, the IMINT production unit may have the collection services of special aerial surveillance aircraft that are allocated for use on a mission per unit time basis. At the tactical level, both Army corps and division commanders will require imagery interpretation support. The MIBARS* does not have any organic collection assets. Allocation of collection assets is coordinated through the G-2 Air in the Tactical Operations Center. The G-2 will be cognizant of both division and corps level IMINT production capabilities. The G-2 will also coordinate the prioritization and allocation of collection assets for meeting the needs of Corps and Division commanders.

The MIBARS detachments interface directly with the tactical squadrons (Mohawk or AF tactical reconnaissance) that fly the missions through the Air Reconnaissance Liaison Officer (ARLO), who will be collocated with the tactical unit. In some cases, one or more MIBARS detachments may be resident at the tactical air base with the reconnaissance aircraft. The MIBARS has U-8 and U-21 aircraft for use in pickup and delivery of film or imagery products.

Mission coordination at the tactical level includes two additional activities:

(1) Pre-flight briefings of pilots on requirements and threats (responsibility of ARLO)

(2) In-flight mission coordination to exploit real-time imagery transmitted to ground interpretation stations.

The scope of interpretation that can be performed by an II is heavily dependent on awareness brought about by exposure to collateral intelligence and awareness of other intelligence activities and capabilities. This category of information is extremely broad and includes HUMINT and open source

*Military Intelligence Battalion Air Reconnaissance Support

materials. Characteristically, it is at the II analyst's own initiative that these materials are collected, organized by area of interest, and applied to the imagery interpretation process.

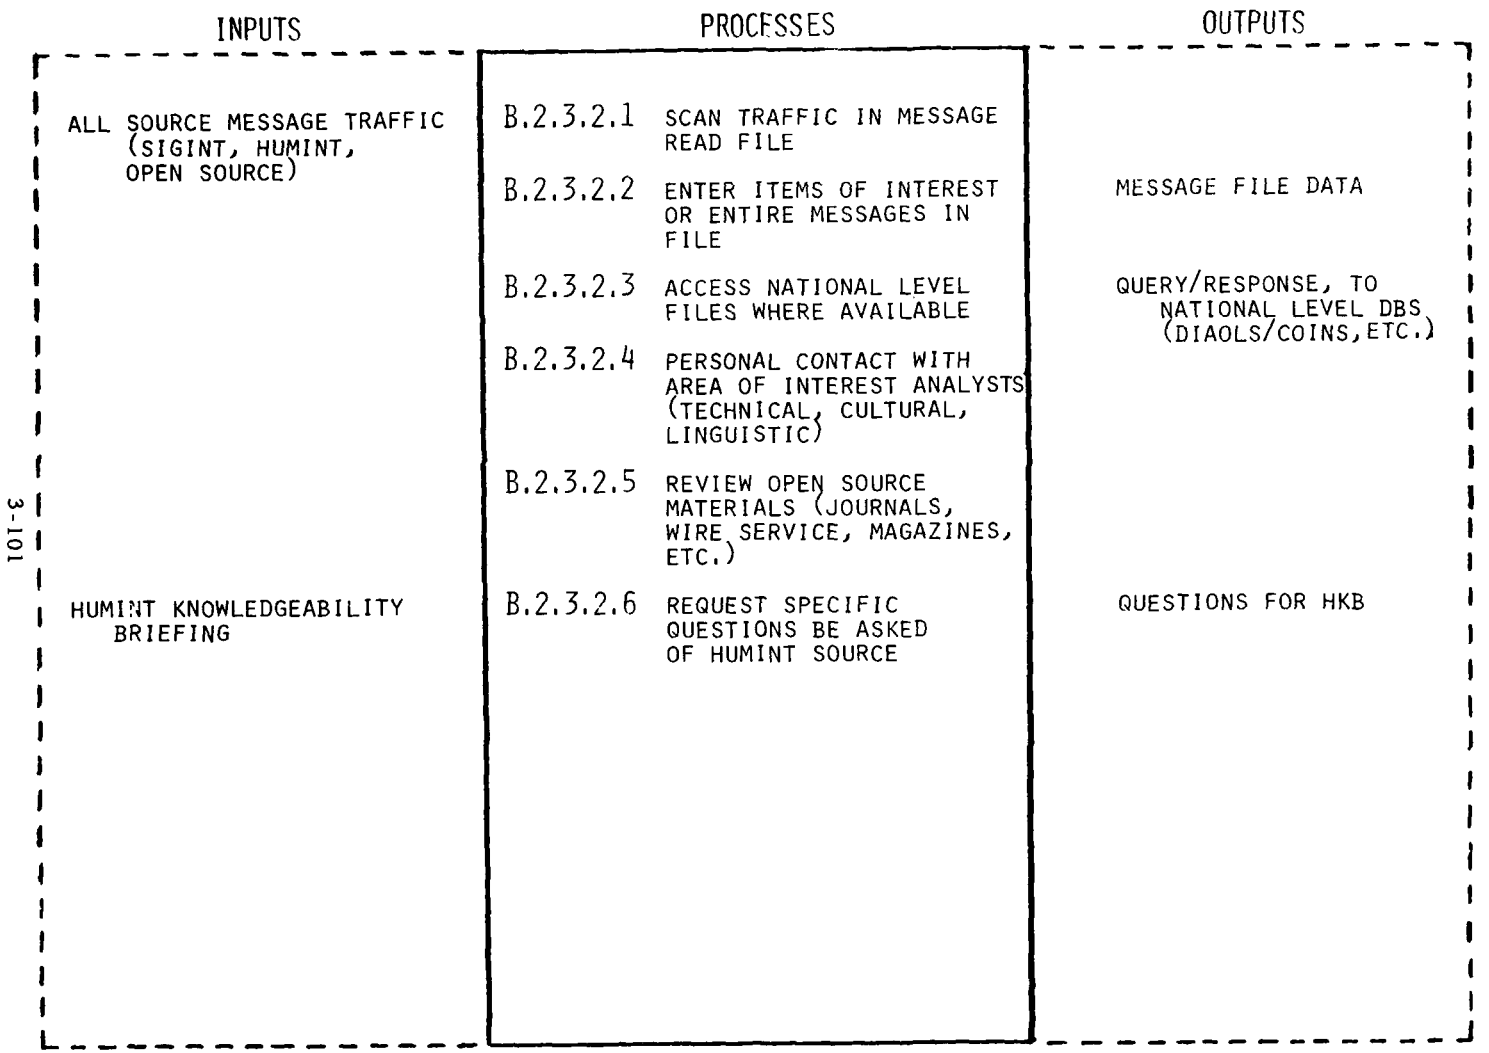
In many cases the collateral materials work in an indirect manner, such as open-source photographs of non-military targets which aid in screening potential military targets in surveillance photography. Collateral materials such as HUMINT intelligence reports can identify general areas and types of military targets that are to be searched for and identified through image interpretation.

In terms of the IMINT Production model, collection of collateral intelligence materials is of concern from the following perspectives:

(1) Are there means of formal representation of an II analyst's area of interest for screening useful collateral materials?

(2) How can the content and application of collateral materials be represented in terms of entry points to a data base that can be managed and exploited by the overall IMINT production facility?

B.2.3.2 ALL SOURCE DATA REVIEW AND REDUCTION



* indicates expansion of function in following pages

B.2.3.2. All Source Data Review and Reduction

An IIA is essentially an entrepreneur whose success or failure depends upon his own intelligence, intuition, and aggressiveness in the pursuit of information. Although some national level imagery interpretation resources such as NPIC have a position dedicated to collateral research in each branch, most image interpreters carry out their own collateral and all source research. In general, IIAs will receive message traffic presumably relevant to their particular imagery interpretation area, but in most cases, such traffic does not come to them directly, but must be selected by individual image interpreters from the volume of traffic disseminated to a particular group or element. Similarly, data reduction from this volume of traffic is carried out by individual IIAs, who conduct a continuous 'reconnaissance' for particular items of interest in their area of responsibility. In the case of the national resources, some of this burden of continued awareness toward new information from any source is alleviated by the message, installation and target data bases existing at this level, but generally speaking, the IIA is his own information researcher.

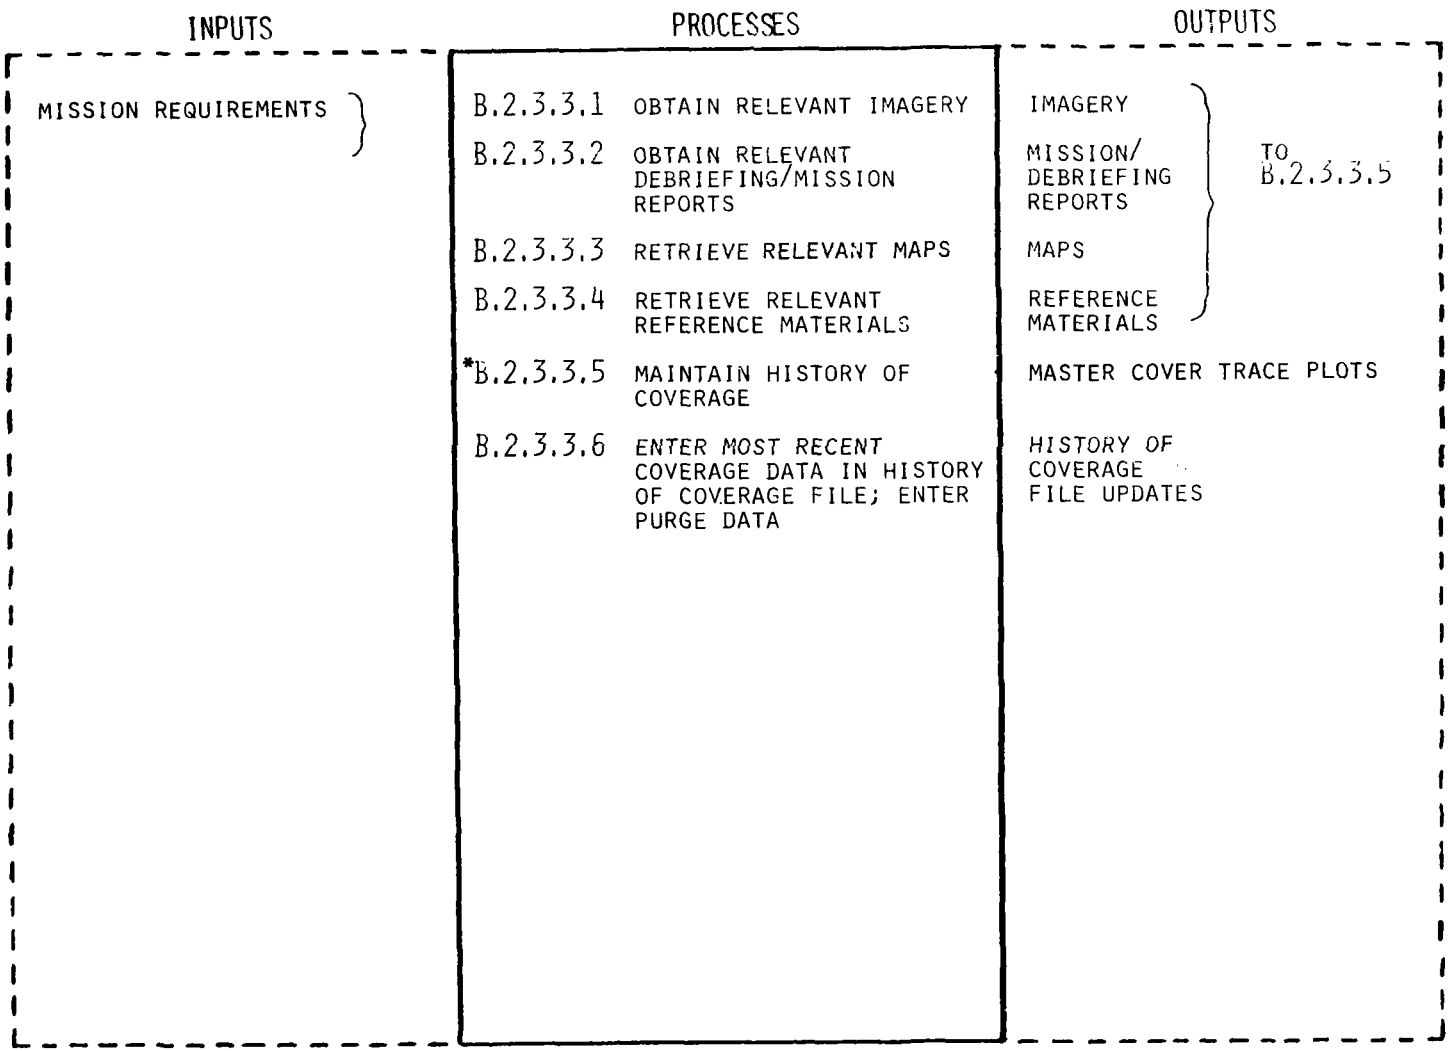
The IIA may have the opportunity to gain directly related intelligence information through personal contacts with other analysts in other intelligence disciplines with interests in the same targets (e.g., SIGINT, OB areas). The IIA is in turn an informal information source to those analysts.

Queries to national or theater level data bases can be made directly if terminals are available or indirectly through a support group.

Analysts may have interaction with HUMINT sources indirectly through HUMINT knowledgeability briefings or directly where they are collocated with an IPW group.

Interviewed analysts gave examples of Vietnam experiences in which imagery analysts were able to provide cues to interrogators for lines of questioning.

B.2.3.3 HISTORY OF COVERAGE MAINTENANCE



* indicates expansion of function in following pages

B.2.3.3 History of Coverage Maintenance

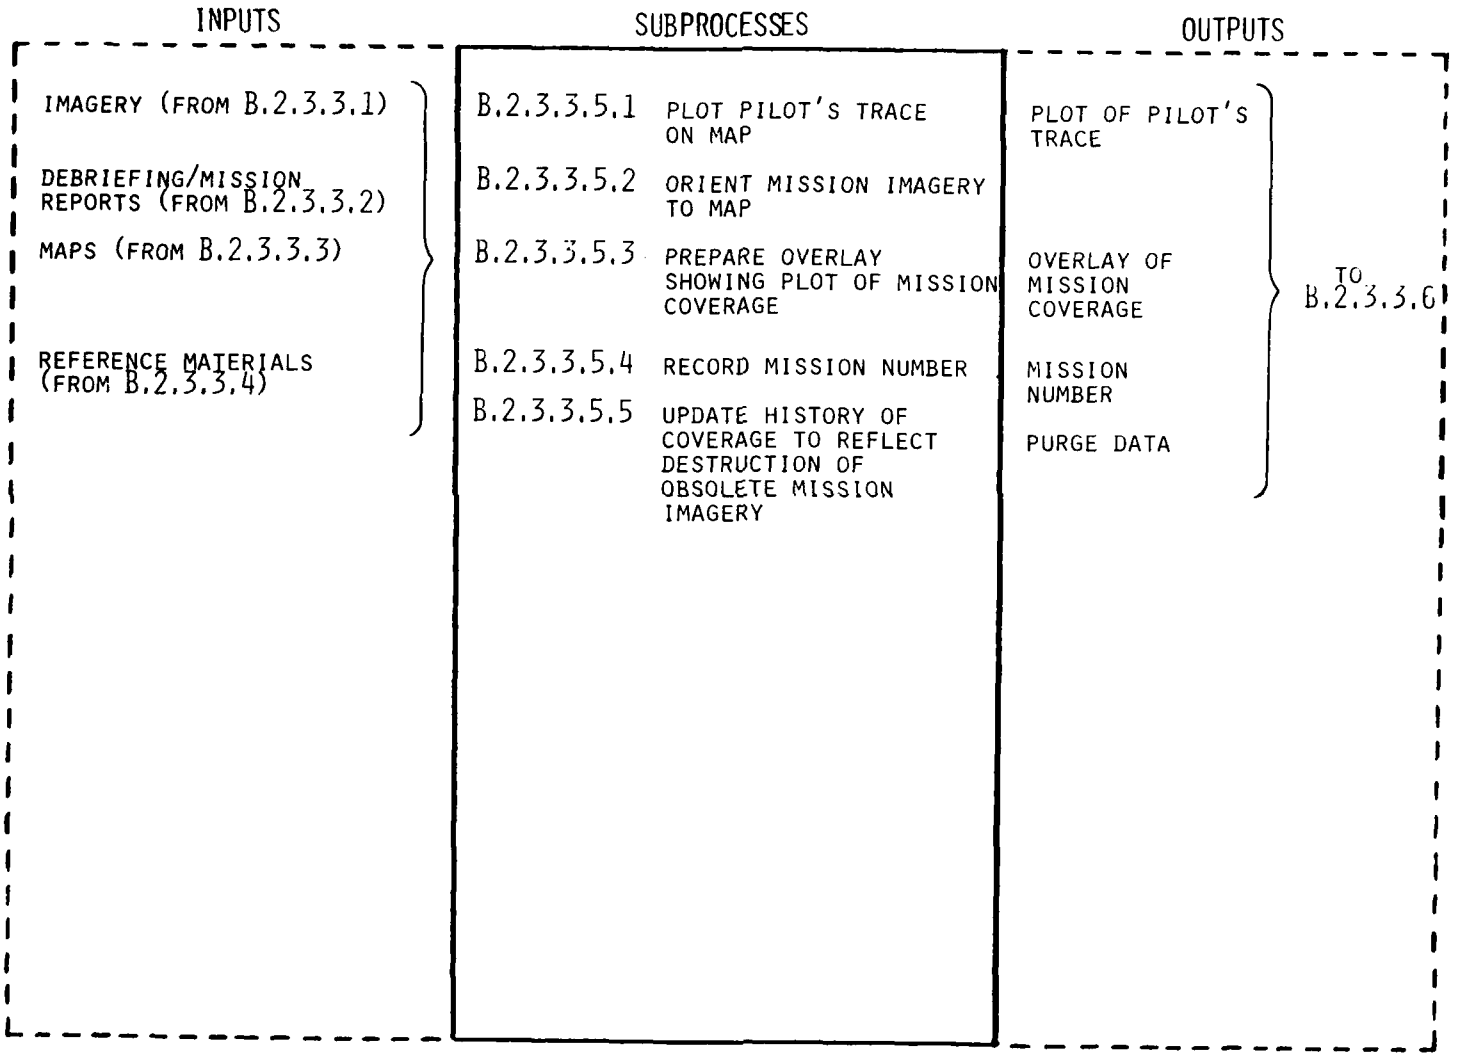
An extremely important support activity of the imagery interpretation process is the generation and maintenance of a detailed history of all imagery on hand -- that is, the support of a history of coverage file.

In the tactical area, such a history is maintained in terms of the so-called 'Master Cover Trace', a basic map with all associated missions represented in terms of the pilot's trace, or flight line flown by the airborne platform, and related debriefing and mission report indexes. On the national level, most coverage data is maintained by automated systems designed for this purpose.

In second and third phase II processing, past imagery coverage is extremely important in change detection and performing negation analysis when a target is detected.

Because of large volumes of imagery that can be accumulated by a facility with an active mission, a library capability -- often a rudimentary one constrained by the availability of important personnel, and storage -- is required for storage, indexing (by mission, target, location), and control of film and hardcopy materials.

B.2.3.3.5 MAINTAIN HISTORY OF COVERAGE

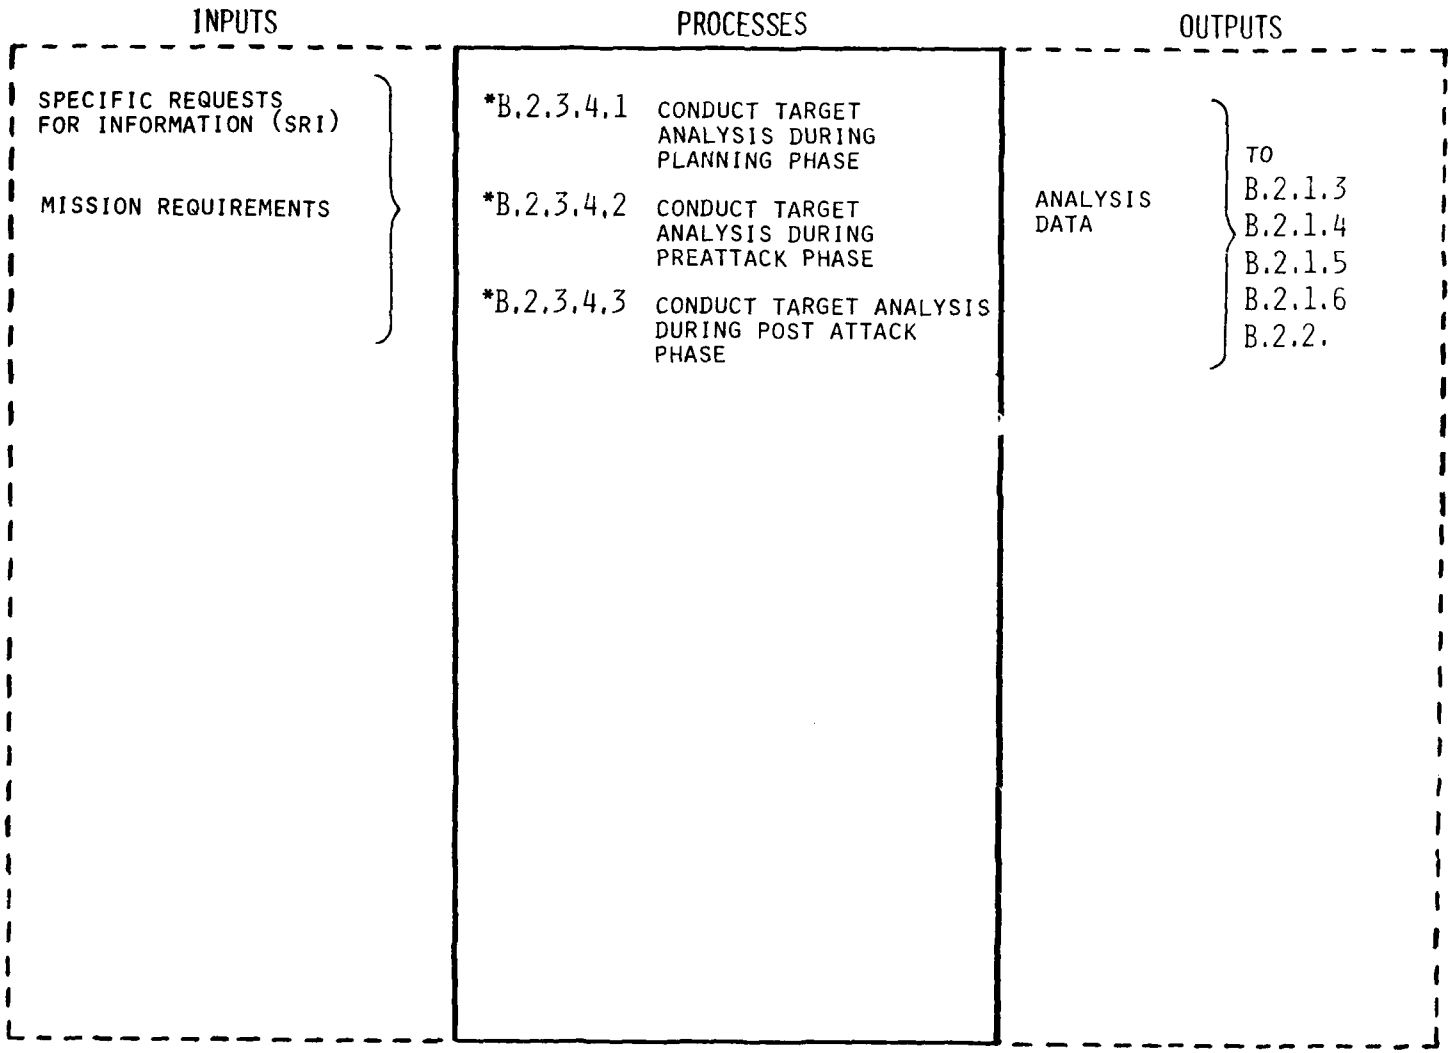


* indicates expansion of function in following pages

B.2.3.3.5 Maintain History of Coverage

The basic subprocesses involved in this activity are the relation of a particular mission flown by a given aircraft to a map designating the coverage of a particular geographic area, the update of such a master cover record in terms of each new mission flown, and the amendment of mission records to reflect eventual purge and destruction of associated imagery, as it becomes obsolete.

B.2.3.4 TARGET ANALYSIS/DEVELOPMENT

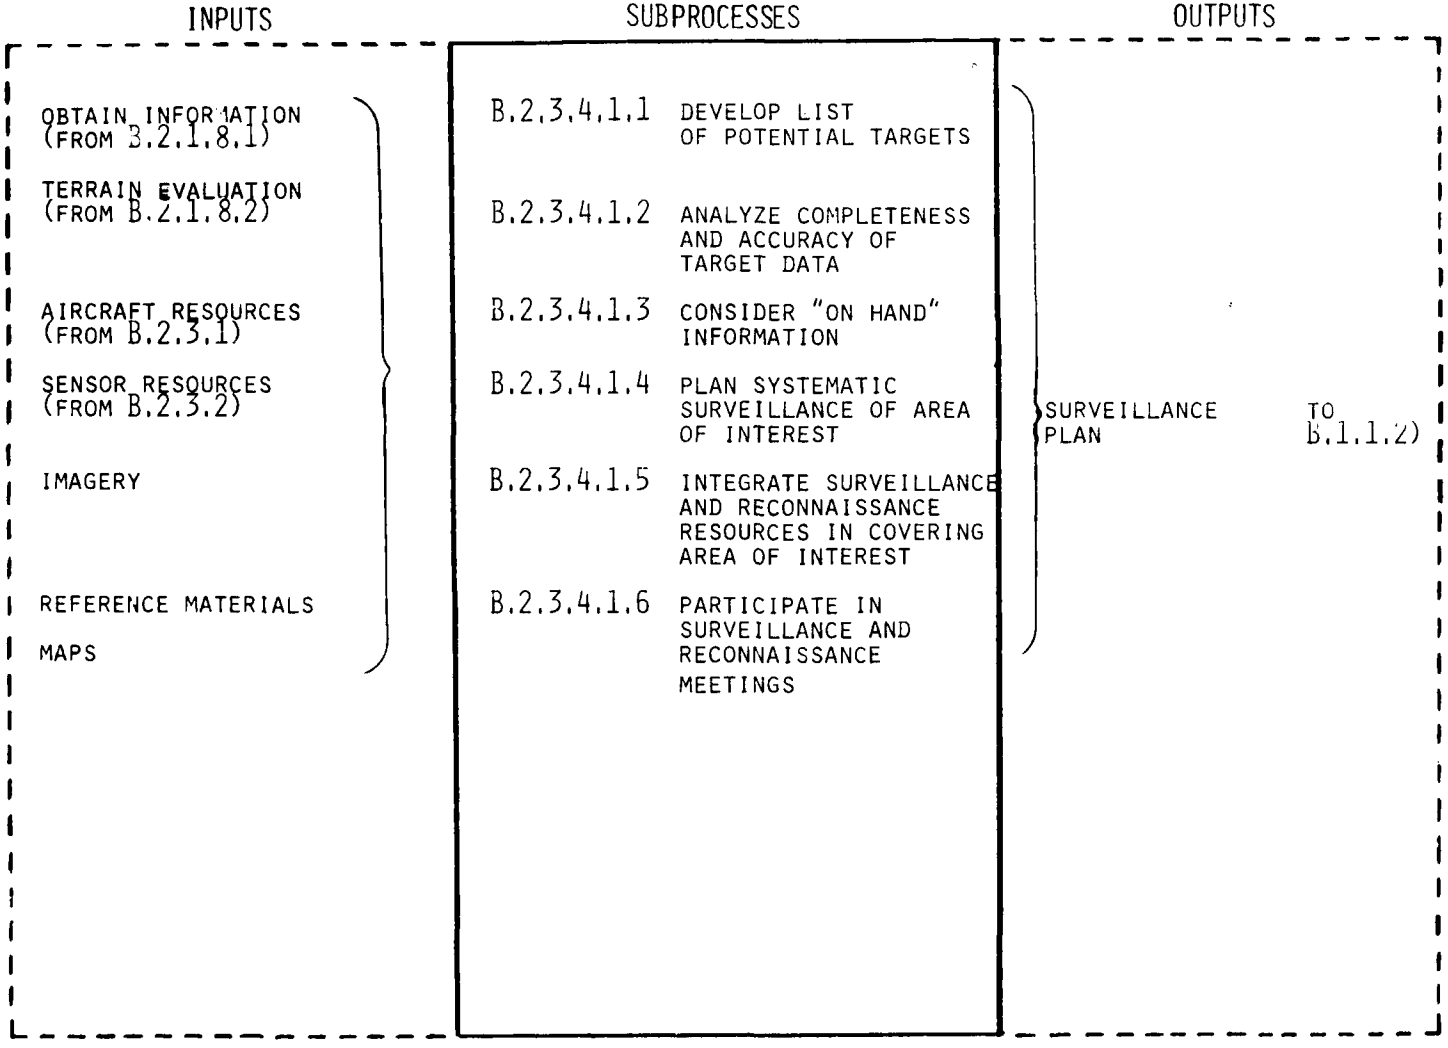


* indicates expansion of function in following pages

B.2.3.4 Target Analysis/Development

Although target analysis and development is being continually carried out on the strategic level in the areas of foreign technology assessment and other scientific and technological areas, target analysis and development processing on a tactical level tends to be more oriented toward a specific objective and associated plans of attack. In the following discussion and the associated charts, the tactical view is treated.

B.2.3.4.1 CONDUCT TARGET ANALYSIS DURING PLANNING PHASE



* indicates expansion of function in following pages

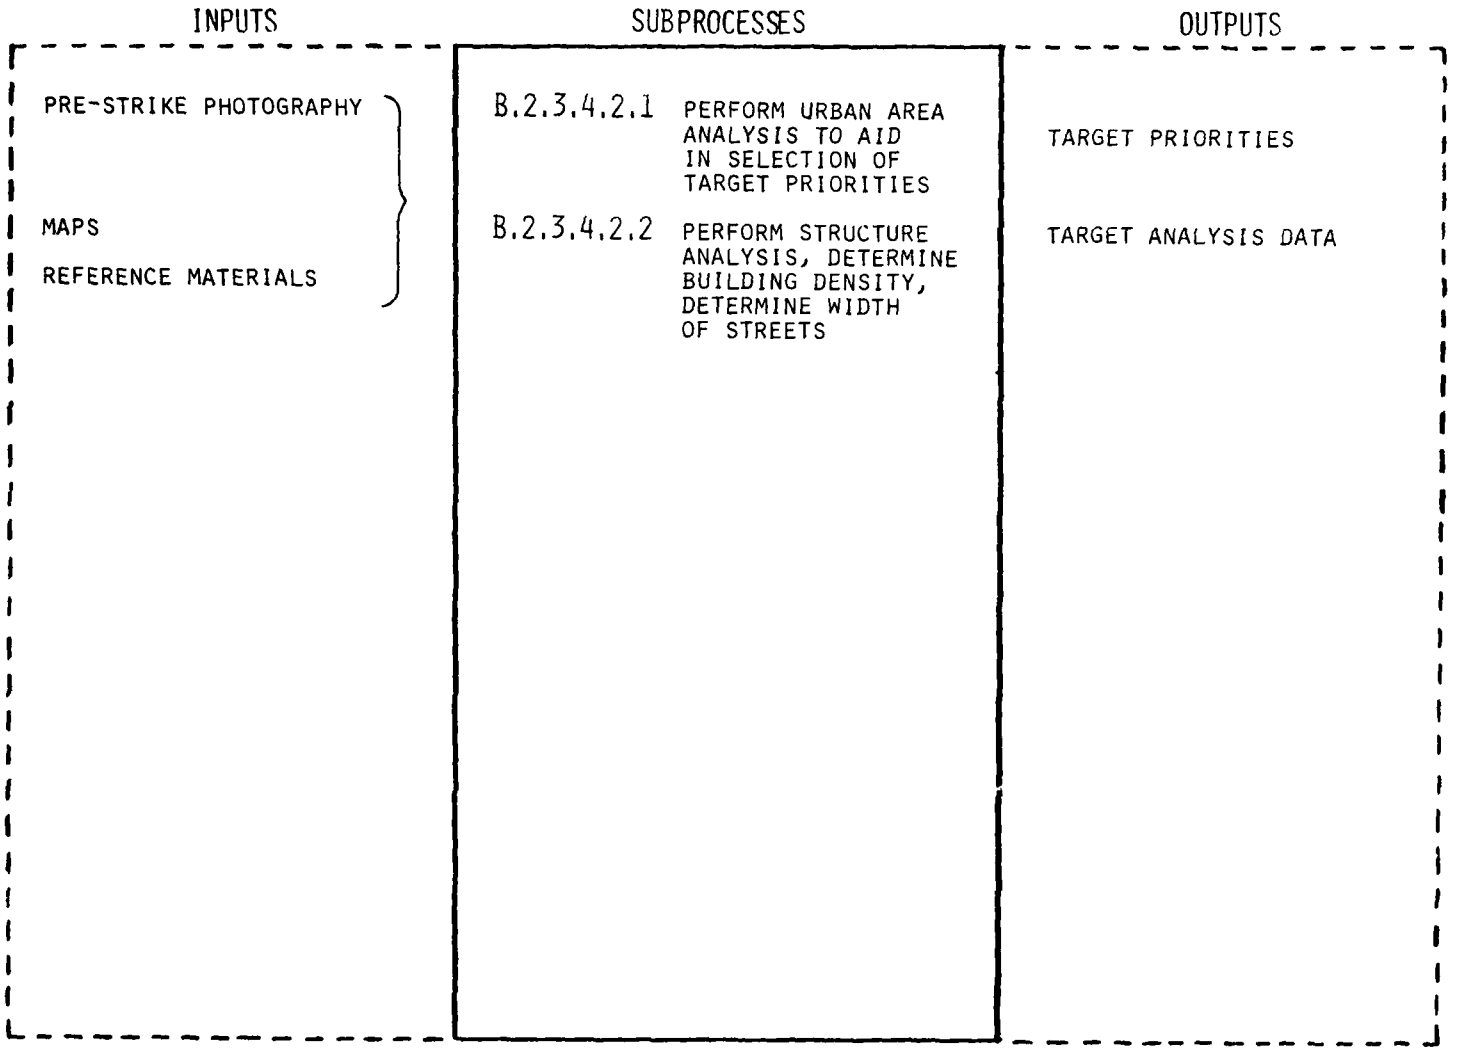
B.2.3.4.1 Conduct Target Analysis During Planning Phase

In a tactical situation, for any given state of affairs in crisis or wartime, the processing associated with the development of detailed information on targets begins with the creation of an inventory of potential targets in the affected area relevant to the planned attack. The initial steps involve an assessment of the completeness and accuracy of target data immediately available, and on hand within a given targeting information system.

This initial review of available information is followed by a planning phase aimed at developing additional required information -- essentially, the filling in of the variety of gaps which may exist in target information -- by systematic surveillance of the area or areas of immediate military interest.

This plan for systematic surveillance of areas of interest for particular elements must then be integrated with other similar plans generated by other elements in order to provide for an integration of surveillance and reconnaissance resources in providing the desired coverage of the area(s) of interest.

B.2.3.4.2 CONDUCT TARGET ANALYSIS DURING PRE-ATTACK PHASE



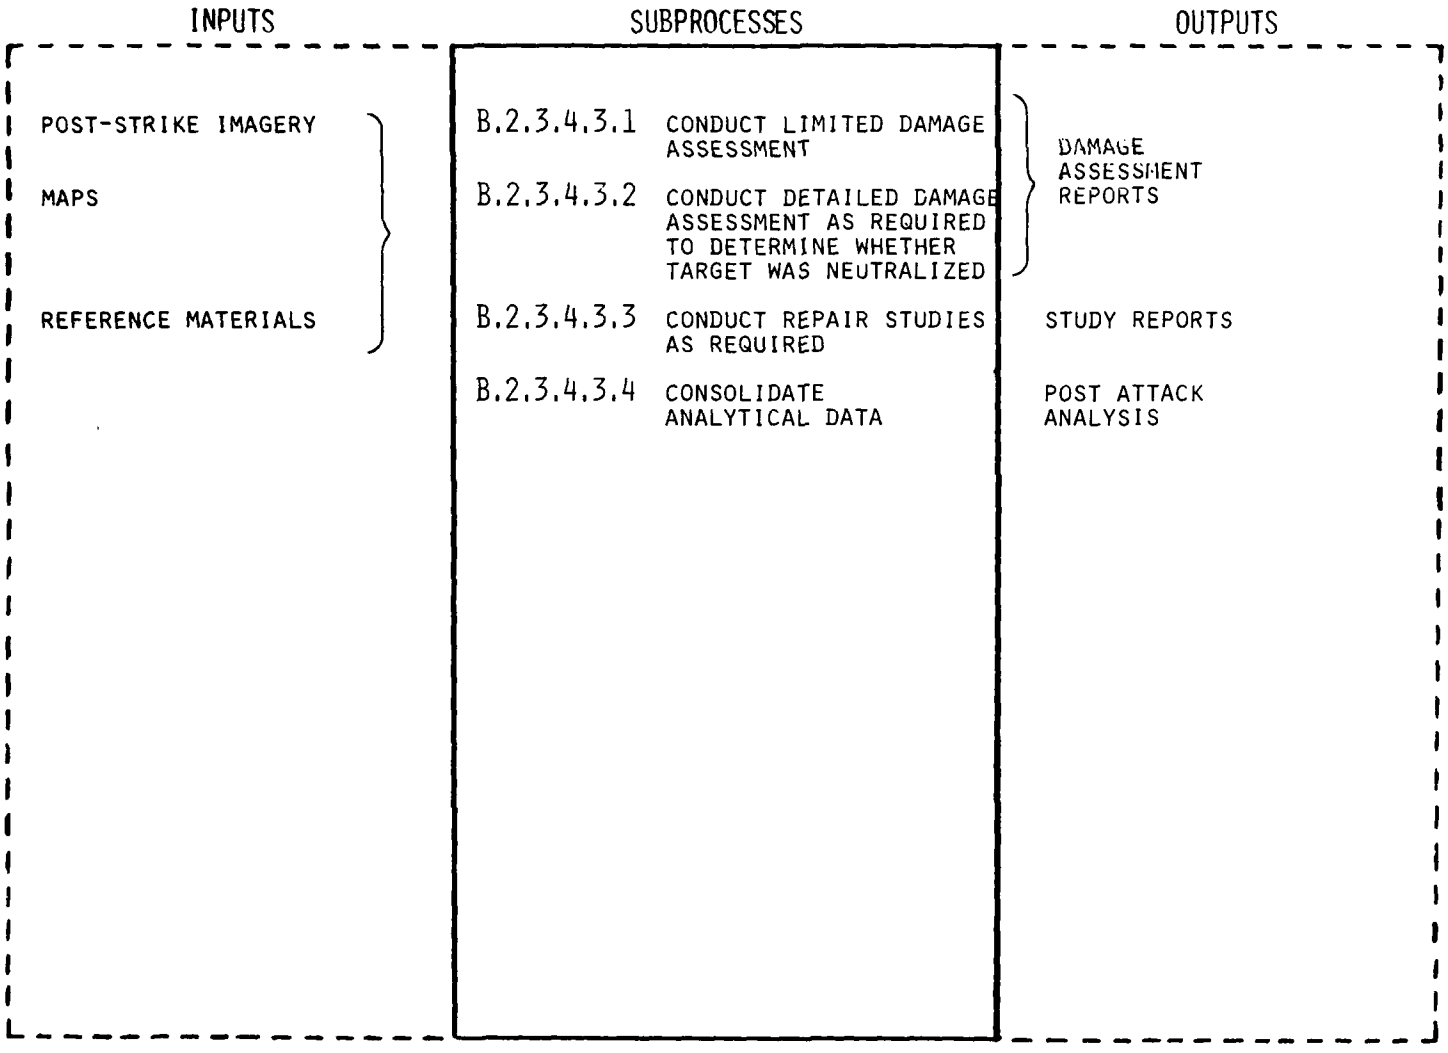
* indicates expansion of function in following pages

B.2.3.4.2 Conduct Target Analysis During Pre-Attack Phase

In the pre-attack phase of tactical operations, particular attention is devoted to urban area analysis, as a basis for selecting target priorities for attack forces, assuming urban targets of interest in the combat area.

Detailed urban area analysis calls for structural analysis of buildings to determine height, degree of reinforcement, special characteristics, such as built-in air raid or nuclear shelters, observation points, and the like, density of building structures in various sectors of the urban area, width of streets and trafficability for armored forces of various types, population density by sector, etc.

B.2.3.4.3 CONDUCT TARGET ANALYSIS DURING POST-ATTACK PHASE

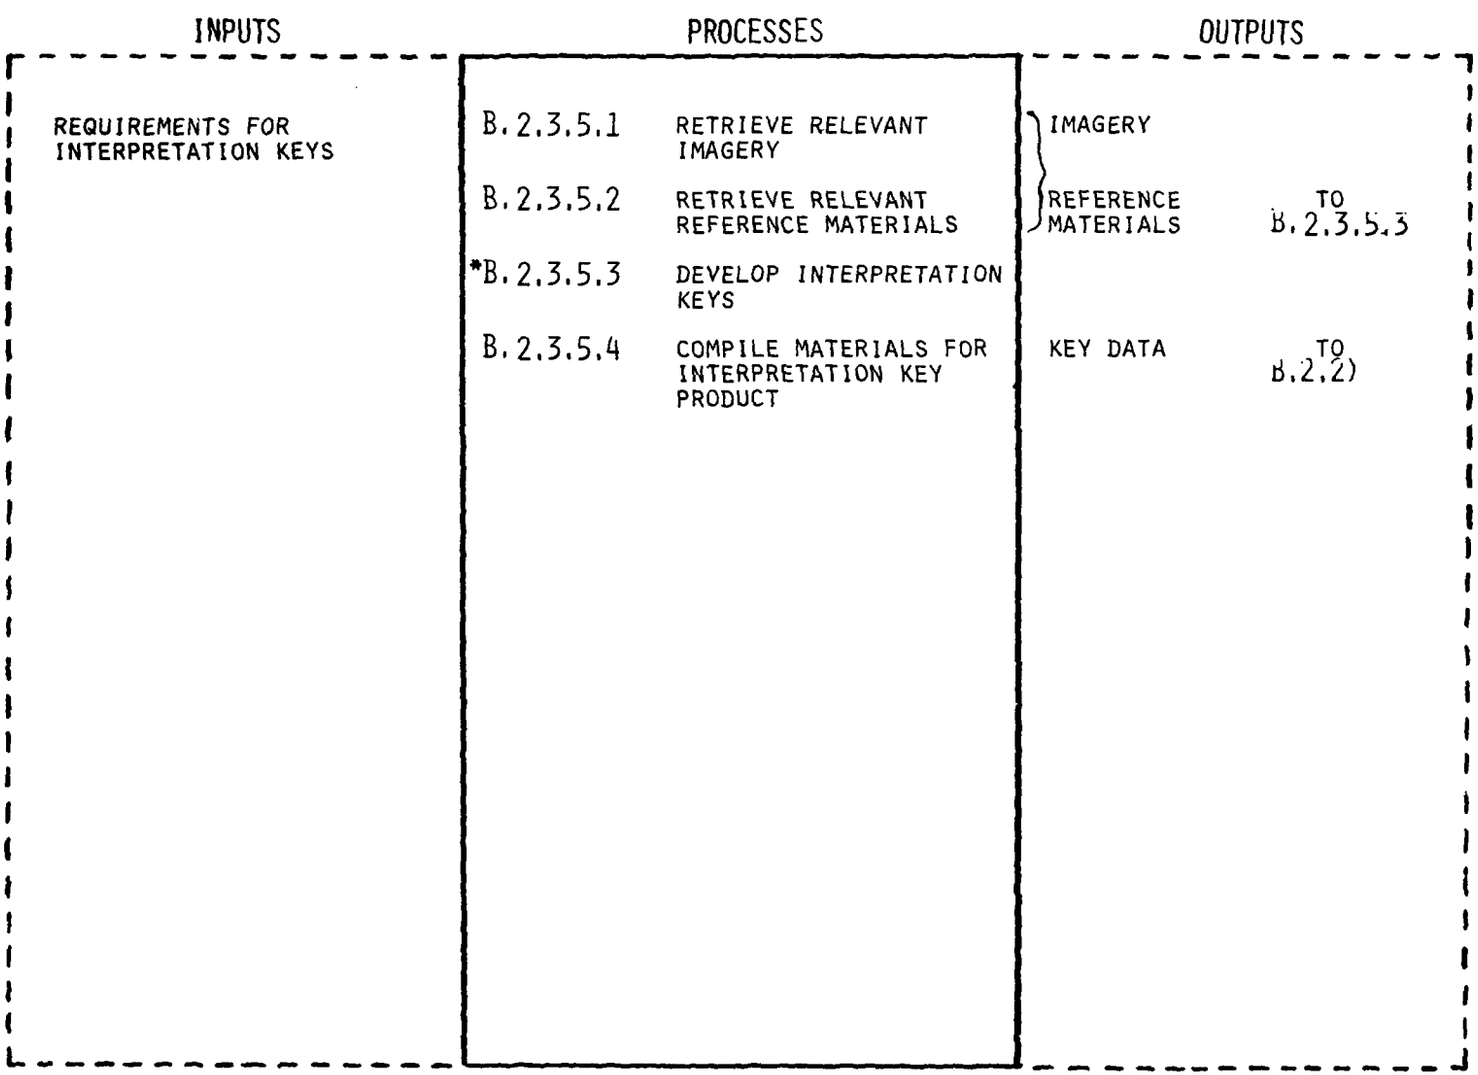


* indicates expansion of function in following pages

B.2.3.4.3 Conduct Target Analysis During Post Attack Phase

Target analysis in a tactical level post-attack context is primarily concerned with assessing the amount of damage inflicted by the given attack, evaluation of suppression or neutralization of a particular target, and estimates of repairs involved before the particular target facilities can become operational again.

B.2.3.5 INTERPRETATION KEY DEVELOPMENT

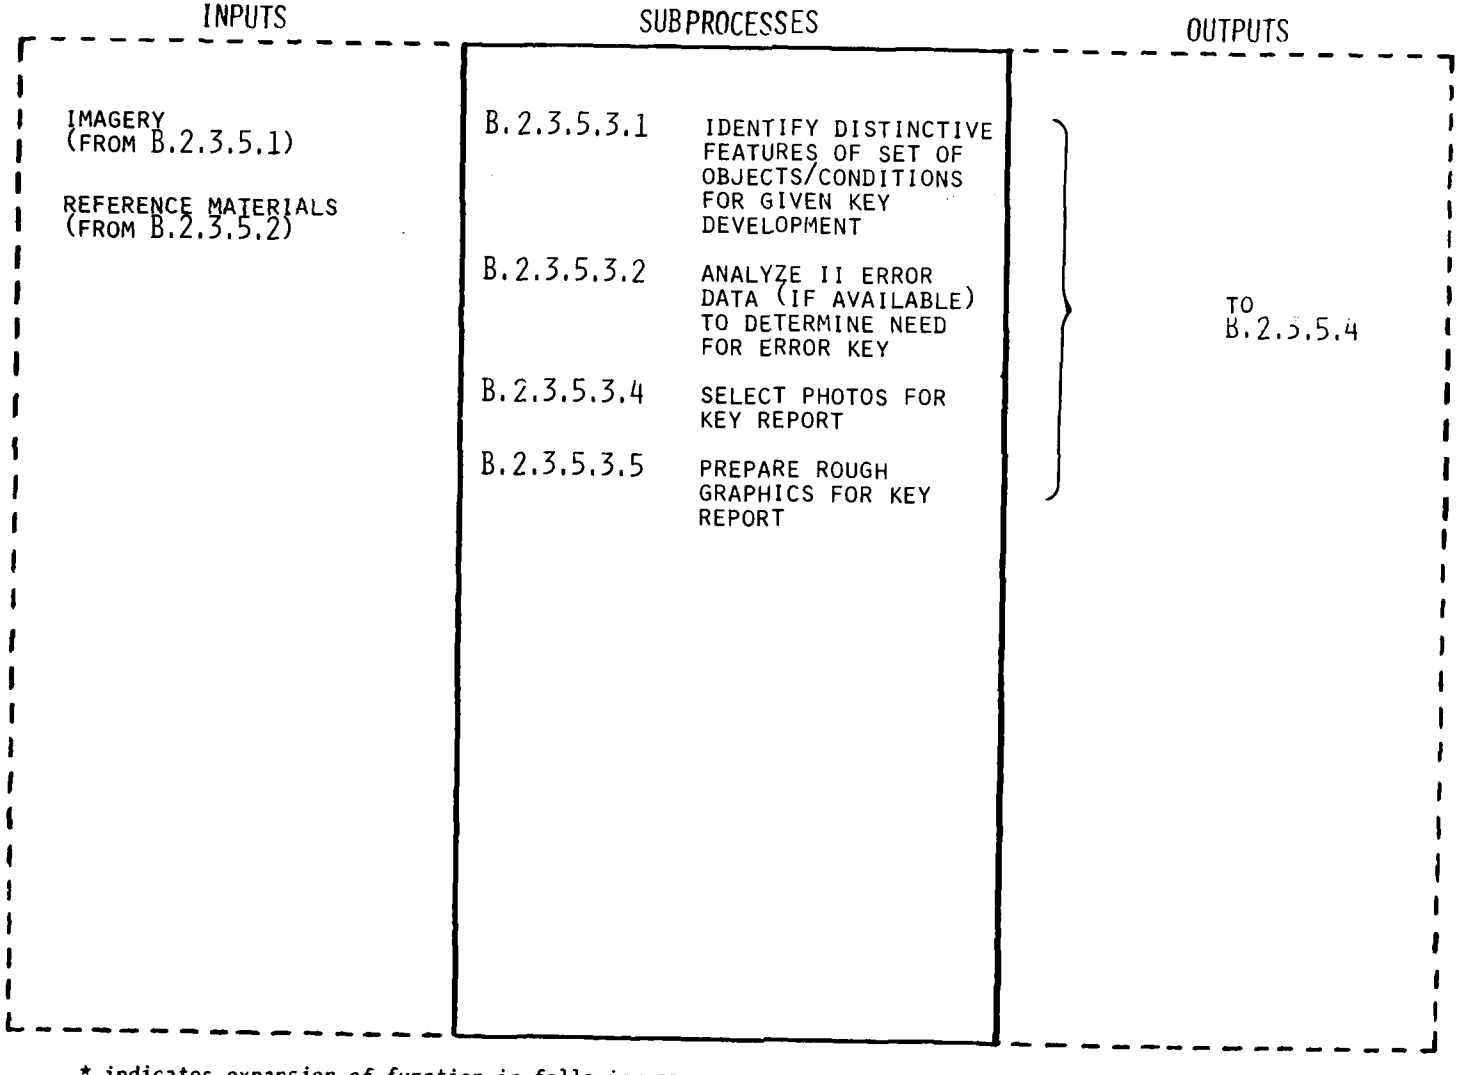


* indicates expansion of funct ı in following pages

B.2.3.5 Imagery Interpretation Key Development

On the level of the national imagery interpretation resources, development and maintenance of aids to the imagery interpretation process is an important research area. Based on all available materials -- including all source message traffic and hard copy reports, as well as all types of imagery relevant to the particular object, equipment, condition, or characteristic -- the objective is to develop concise and accurate materials for distinguishing items of known or potential military significance.

B.2.3.5.3 DEVELOP INTERPRETATION KEYS



* indicates expansion of function in following pages

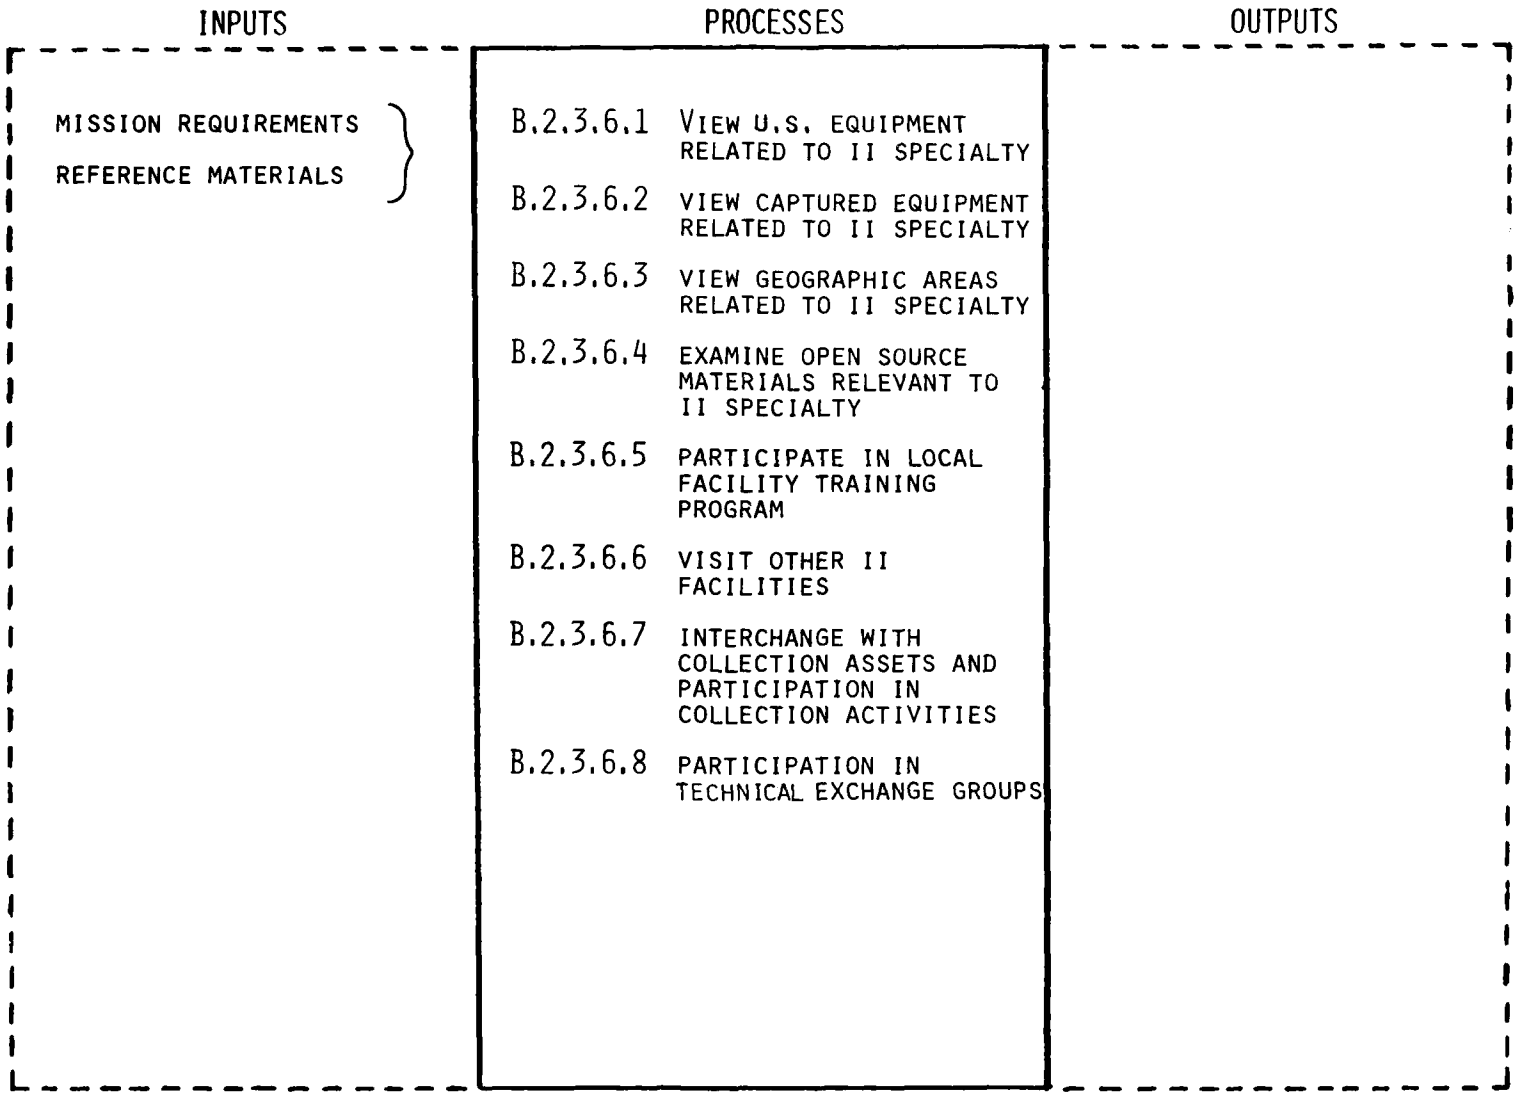
B.2.3.5.3 Develop Interpretation Keys

In developing a key for a particular set of objects, special care is devoted to identification and specification of features distinguishing different members of the given set. To illustrate: in the distinction of members of the set of U. S. Army trucks, an important distinctive feature is existence of an engine hood (distinguishes infantry weapons carrier versus cargo trucks), and number of bows on the top (cargo vehicles of differing capacities).

A related consideration involves the requirement for error keys (discussed under B.2.1.4) to avoid misidentification of items of military significance as non-military items which exhibit considerable similarity in structure, and conversely, the misidentification of non-military items as objects or charcteristics of military significance.

The materials developed in the light of these guiding principles will form chapters of the imagery interpretation documentation currently under development, and will utilize the best of available imagery supplemented by artist drawn graphics in a readily comprehensible format to provide effective imagery interpretation aids.

B.2.3.6 KNOWLEDGE BASE AND SKILL DEVELOPMENT



* indicates expansion of function in following pages

B.2.3.6 Knowledge Base and Skill Development

The training, maintenance, and enhancement of an image interpreter's skills and abilities is of paramount importance to effective, reliable, imagery interpretation at all levels. At the national level, in addition to the customary training and proficiency maintenance programs, image interpreters are involved in programs for enhancing their effectiveness and ability by a series of travel programs aimed at exposing them to U. S. equipment or developments related to their specialty, at viewing captured equipment in an environment similar to the actual operational environment in which it functions, and at viewing geographic areas similar to those in the image interpreter's area of responsibility. Moreover, image interpreters are provided with a variety of open source materials which complement and supplement the imagery they are required to interpret. Although such intensive programs do not currently exist on the level of the tactical image interpretation element, the need for them is widely recognized.

Formal Training

Formal training in general II skills is not available for all skill levels in the Army 96D II specialty. The USAICS II courses at Fort Huachuca cover only skill levels 1 and 2 plus the 35C officer course. The enlisted course for skill level 1 addresses 22 basic field skills:

(1) Security

(2) Photo interpretation

(3) Code matrix

(4) PI slide rule

(5) Photogrammetry

(6) Overlay preparation

(7) Plotting

(8) Terrain

(9) Road classification

(10) Bridges

(11) Ports, Harbors, Inland Waterways

(12) Railroads

(13) Airfields

(14) Tactical identification

(15) Installations

PRECEDING PAGE BLANK - NOT FILMED

(16) Order of Battle

(17) SLAR

(18) IR

(19) Mosaics

(20) Reports

(21) References

(22) TIIF

These courses introduce the novice II to the field but do not fully prepare the individual for an operational role. Unit training and apprenticeship type experience are expected to qualify the II for an active role in the II production process.

Advanced schools such as the DSIATP at Offutt Air Force Base or the NPIC school are aimed primarily at analysts going into assignments within national level organizations. These programs must cover military doctrine and technical subjects as well as imagery interpretation technique. Students in general will not have sufficient field experience, prior training, or technical backgrounds to permit the courses to focus exclusively on technique. Organization of the advanced courses is substantially different from basic courses in orientation toward target types. The segments taught at Offutt are:

Introduction

Military Geography

Photogrammetry

Ground Forces

Strategic Industries

Electronics

Offensive Missiles

Air Forces

Defensive Missiles

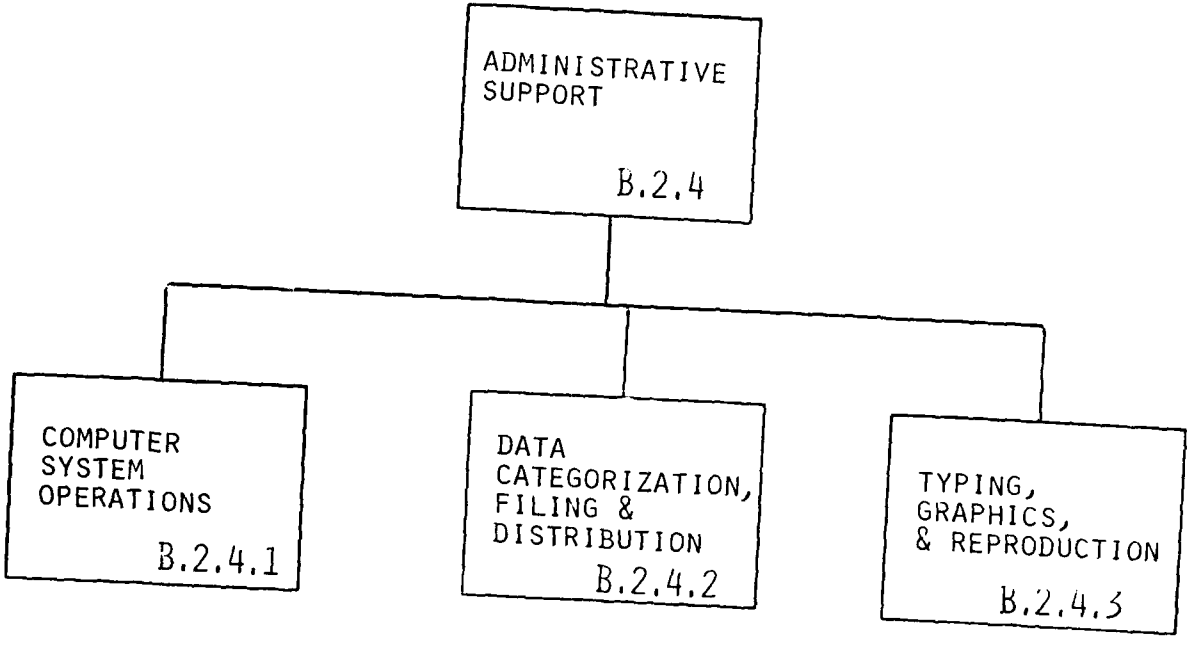
Naval Forces

Unit Training

A graduate of the DSIATP school has been trained to think like an imagery interpreter but unless his DSIATP training was preceded by relevant operational experience, he will not be capable of assuming responsibility for an active mission until he receives additional unit training at his next assignment. It is left to unit training to convey the "big picture" knowledge and tricks of the trade to the inexperienced.

Staff rotation also creates a need for the same type of unit training. It was frequently stated by interviewed analysts, that overlap time between beginning and leaving personnel was insufficient to pass along the legacy of past experience, thereby creating a necessity for self-taught skills and knowledge. An agressive, motivated analyst considers this type of environment as a professional challenge especially when supportive assistance and positive feedback are provided by management and peers.

Image interpretation was described by an advanced training instructor as essentially "an oral tradition". One image interpreter learns from another by working with him and talking about his methodology. Moreover, experienced image interpreters seem to share a special concern for informal training of novice image interpreters. Thus, although the importance of formal training cannot be underestimated, much of the image interpreter's skill derives from informal, learning, relationships with other II's.



ADMINISTRATIVE SUPPORT
B.2.4
COMPUTER SYSTEM OPERATIONS
B.2.4.1
DATA CATEGORIZATION, FILING & DISTRIBUTION
B.2.4.2
TYPING, GRAPHICS, & REPRODUCTION
B.2.4.3

B.2.4 Administrative Support

Administrative support processes in the II facility are tailored to suit the production level, mission, and data processing needs.

B.2.4.1 Computer System Operations

Operation of computer systems which support the management of tasking, production data, or data bases can be considered as falling within this category. Tasking would include computer system operator functions (starting, shutdown, configuration control, diagnostics, etc.) data entry, data base management, report generation, and user assistance. Use of computers for administrative support in II facilities is mostly restricted to national level facilities, at the current time. Field level use of computers such as in the TIIF is mainly for computational applications. Future systems will make extensive use of computers for communications and data base management as well as computation.

B.2.4.2 Data Categorization, Filing, and Distribution

An important administrative task is the handling of materials coming into the facility, generated within the facility, and leaving the facility. Major categories of material include:

- Procedures
- Handbooks
- Manuals
- Technical References
- Maps
- Requirements (message, letter, etc.)
- Handheld photography
- Mission film
- Open source technical journals, books, magazines, newspapers, wire service stories
- Intelligence reports
- Message traffic
- Technical exchange memoranda
- Production schedules
- Photocopy/graphic requests
- Imagery duplicates
- Personnel and equipment status
- Weather data
- Coverage history file
- Product file
- Target folders
- Mission data
- Collection Plan
- Sensor capabilities
- Intelligence analyst directories
- All-source intelligence materials

Much of the responsibility for collecting, categorizing and filing these materials rests with the analysts and control of the process may be informal along lines of interest. However, on a broad scale, informal control results in a much narrower range of materials available to individual analysts, awareness of other intelligence information is lost, and duplication of efforts cannot be controlled.

The availability of automated data processing technology has had an impact in two important aspects of this function. First, it has made it possible to maintain an integrated data base of mission parameters, tasking, and output reports. This data base capability alone has greatly improved the productivity and responsiveness of the II facility and helped eliminate duplication of effort.

The second area where automated data processing is beginning to have an impact is in the area of accessing and distributing intelligence materials on the basis of content. An automated data base containing past imagery coverage that can be searched by location parameters, time, or mission number is extremely valuable in exploiting previous missions. On a broader scale, all-source intelligence can be made more readily available for exploitation in the imagery interpretation process if it is available in a computerized file that is searchable by:

location parameters

country name

place name

time

keywords

Certain types of all-source intelligence materials are searchable in data bases maintained at the national level. Access is limited to special terminals, some which can be connected remotely through communication channels. Multiple terminals and query languages are required to access the host computer systems that maintain these data bases. Frequently, a specialist is required to operate the terminal systems for the analyst without time to learn the protocols and peculiarities of the different systems.

One means of distributing time-critical requirements and intelligence information is through global message communication networks that are accessible by every II facility. Current Army tactical facilities interface with the message communication network through hardcopy for both sending and receiving. New automated message handling technology which is in use at the national level and in prototype tactical facilities provides a direct interconnection to the world wide message communication network from computer terminals. Using these automated systems, image interpreters and other intelligence analysts can review intelligence reports or other message traffic relevant to their work area. Most time critical intelligence information passes through the message handling network, either when first generated or as an exploitation product. Message dissemination technology has been developed for automatic monitoring of the message traffic flow, filtering out relevant messages, and filing these messages for subsequent use in intelligence processing. This technology would replace the existing manual operation in the II facility which involves each analyst in perusing stacks of hardcopy messages distributed to the facility in general.

B.2.4.3 Typing, Graphics, and Reproduction

The level of administrative support provided in the II facility for product preparation and publication is variable depending on the staff size, workload, and applicable product standards for the user community. Products which have extremely wide distribution and a longer useful life are published to higher standards. Special staffing is provided to produce graphics, photocopy, and final type for facilities which produce a substantial volume of high quality products. Most facilities have some level of administrative support for these activities to give interpreters more time for analysis tasks. Automated data processing systems are beginning to impact this area.

In new systems, analysts are being given CRT terminals for entering processing data, editing, and report generation, typically referred to as word processing systems.

Integration of the word processing capabilities, data handling, and computational capabilities in a single data processing system is being planned for future systems.

APPENDIX A

Organizations Visited During Data Collection for IMINT Production Model

1. Army Research Institute (ARI)/Human Factors Technical Area
2. HQ US Army Intelligence and Security Command (INSCOM)/IASYS
3. US Army Intelligence Center and School/Director of Training, Fort Huachuca, AZ

FORESTER'S GUIDE TO AERIAL PHOTO INTERPRETATION

T. Eugene Avery

U.S. Department of Agriculture
Forest Service

Agriculture Handbook No. 308
October 1966
Slightly revised December 1969

For sale by the Superintendent of Documents, U.S. Government Printing Office
Washington, D.C. 20402 - Price 75 cents

This handbook is a revised and enlarged version of Occasional Paper 156, issued by the Southern Forest Experiment Station, New Orleans, La., in January 1957. The text and illustrations have been broadened to include most of the United States and parts of Canada.

Dr. T. Eugene Avery, formerly with the Division of Forest Economics Research at the Southern Forest Experiment Station, is Professor of Forestry and Head, Department of Forestry, University of Illinois, Urbana, Ill.

FORESTER'S GUIDE TO AERIAL PHOTO INTERPRETATION

This handbook was written as a practical reference on techniques of aerial photo interpretation in forest inventory. It is for the forester with a casual knowledge of the subject. While oblique photographs are occasionally useful for interpretation, this manual emphasizes stereoscopic interpretation of vertical aerial photographs available from various agencies of the U.S. Department of Agriculture (USDA). Figure 1 (foldout, inside back cover) is an example of a vertical aerial photograph.

With training, the forester can use aerial photographs to locate property boundaries and trails, determine bearings and distances, identify classes of vegetation, and measure areas. Experience will enable him to improve the efficiency of forest inventories by distributing field samples on the basis of photo stratifications. In some instances, he may even be able to estimate timber volumes directly from the photographs.

While photo interpretation may make the forester's job easier, there are limitations. Accurate measurements of such items as tree diameter, form class, and stem defect are possible only on the ground. Aerial photographs are best used to complement, assist, or reduce field work rather than take its place.

TYPES OF AERIAL PHOTOGRAPHS [1]

Oblique photographs are taken with the axis of the aerial camera at various angles between the horizon and the ground. *High* obliques show the horizon on the photograph; *low* obliques do not. An oblique photograph covers a larger area compared with a vertical photograph from the same altitude, but its usefulness is limited to fairly level terrain where the view is not obstructed by ridges. For this reason, and because obliques do not readily lend themselves to stereoscopic viewing, they are seldom used by foresters in the United States.

Vertical photographs are taken with the aerial camera pointed straight down at the ground, or as nearly so as feasible. Overlapping exposures in each fight line permit an interpreter to study vertical photographs three-dimensionally with a stereoscope. Because such prints have become so useful for mapping and interpretation, the term "aerial photo" is normally assumed to denote a vertical photograph and will be thus applied in this handbook.

Composite photography is accomplished either by several cameras taking simultaneous pictures, or by one camera having several lenses to provide multiple exposures.

The first approach is exemplified by *trimetrogon* photography, which uses one vertical and two oblique cameras. Combining the three pictures gives photo coverage from horizon to horizon. The system provides relatively inexpensive, small-scale coverage for reconnaissance mapping of large or remote areas.

A second technique, used by the U.S. Coast and Geodetic Survey, employs a special camera having nine lenses. This multiple lens system has proved successful for topographic mapping, but requires expensive photographic and plotting equipment. Its specialized nature makes it generally unsuitable for foresters.

Mosaics are composite pictures assembled from vertical aerial photographs. Individual photographs are cut, matched, and pasted together to give the appearance of a single large print. A mosaic assembled by reference to known points on the ground is called a controlled mosaic; if ground control of linear distances is lacking, the mosaic is called uncontrolled. When carefully assembled, both types provide good map approximations. Mosaics are often used as pictorial displays in offices and public buildings. Professionally prepared mosaics are expensive and cannot be studied three-dimensionally; hence their use by foresters is somewhat restricted.

[1] Adapted from "Forestry uses of aerial photographs," an unpublished training manual of the U.S. Forest Service, Pacific Northwest Forest and Range Experiment Station, 1961.

OBTAINING AERIAL PHOTOGRAPHY

Users of this guide will ordinarily rely on prints of existent photography flown for public agencies. Thus there is no need here to discuss specifications for new aerial photography. Details of flight planning and photographic contracts are covered in the *Manual of Photogrammetry* and the *Manual of Photographic Interpretation* (*1*, *2*).[2]

Sources of aerial photography.—Most of the United States has been photographed in recent years for various Federal agencies. The key to this photography is available free in map form as the "Status of Aerial Photography in the U.S." Copies may be obtained by writing to:

Map Information Office
U.S. Department of the Interior
Geological Survey
Washington, D.C. 20240

This map shows all areas of the United States, by counties, that have been photographed by or for: Agricultural Stabilization and Conservation Service, Soil Conservation Service, Forest Service, Geological Survey, Corps of Engineers, Air Force, Coast and Geodetic Survey, and commercial firms. Names and addresses of agencies holding the negatives for the photographs are printed on the back of the map, and inquiries should be sent directly to the appropriate organization. There is no central laboratory that can furnish prints of all Government photography.

The Agricultural Stabilization and Conservation Service (ASCS) of the Department of Agriculture holds the largest share of the recent aerial photography. ASCS was formerly known as the Agricultural Adjustment Administration (AAA), the Production and Marketing Administration (PMA), and the Commodity Stabilization Service (CSS).

Forest industries often have aerial surveys made of their lands, and ownerships adjacent to or within such areas may be included. Such surveys often are an additional source of photography. The aerial mapping company usually retains the negatives and must have the written permission of the original purchaser before it can sell prints.

Films, season, and date of photography.—Two types of black-and-white aerial film are in common use: panchromatic and infrared. Infrared is usually modified by a minus-blue filter to reduce extreme contrast and improve image resolution. Panchromatic photography offers better resolution and lighter shadows but exhibits little tonal contrast among forest types. Modified infrared photography presents a maximum of contrast between conifers and deciduous hardwoods, but wet sites and shadows register in black, thus restricting interpretation. In Western United States, where coniferous trees predominate, panchromatic film is more likely to be used. Conversely, foresters managing eastern hardwoods often prefer infrared photography because of easier forest type separations. In figure 2, dark-toned pines (A) are readily differentiated from the light-colored upland hardwoods (B) on the infrared stereogram, but there is little tonal contrast on the panchromatic exposures. Also, the farm pond at (C) is immediately seen on the infrared prints, but may be completely overlooked on the panchromatic photographs.

If measurements are needed for deciduous species, both kinds of photography should be taken during the growing season. Infrared is likely to be flown specifically for forestry purposes and usually meets this requirement. On panchromatic photographs taken in winter, conifers can be distinguished from hardwoods, but interpretation of hardwood stand-sizes is difficult. Modified infrared photography is occasionally available for tracts near large forest ownerships or National Forests, but most interpreters will be limited to use of USDA panchromatic photography.

If there is a choice between photography of different dates, one should consider the most recent. In regions characterized by rapid tree growth and frequent cutting, the value of photos more than 5 years old is questionable.

Photo scales and enlargements.—Available aerial photographs range in nominal scale from about 1:12,000 to 1:20,000. Contact prints are standardized at the 9- by 9-inch size. Forest industries often contract for photography at 1:15,840 (4 inches per mile), and some areas in Western United States have been photographed at 1:12,000.

USDA photography is normally at a scale of 1:20,000 (1,667 feet per inch). This is the smallest scale that nonprofessional interpreters with a minimum of equipment can use efficiently. Although enlargements of USDA photography can be obtained, they cost more, yield no additional detail, and cannot be viewed with simple stereoscopes. Contact prints are recommended for general use, unless enlargements present definite advantages in transfer of photo detail to base maps.

Paper surface, weight, and contrast.—USDA prints are available with either glossy or semimatte finishes. Glossy prints exhibit a high degree of resolution and tonal contrast, but their shiny surfaces are difficult to write upon. Semimatte prints are often preferred because they have a minimum of glare, an easily marked on "toothed" surface, and fair resolution qualities.

[2] Italic numbers in parentheses refer to Literature Cited, page 40.

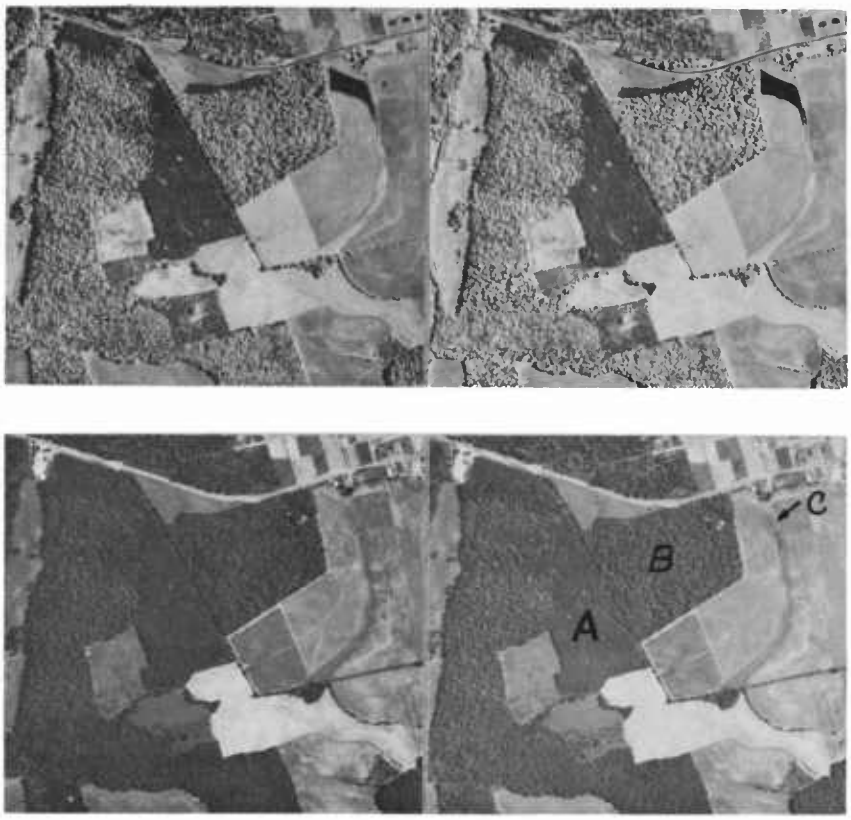

Figure 2.—**Modified infrared (above) and panchromatic photography made in the North Carolina Piedmont during June. Exposures were made simultaneously with a dual aerial camera system. Scale is 1,320 feet per inch. Prints may be viewed three-dimensionally with a lens stereoscope.**

Photographs are available on either single- or double-weight paper. Single-weight paper is suitable for office use, conserves filing space, and is easy to handle under the lens stereoscope. Double-weight paper is preferred for field use, however, because it is more durable and less subject to dimensional changes. Most USDA photography is furnished on double-weight, semimatte paper unless otherwise specified. Contact prints may be obtained on special low-shrink, waterproof paper at a slight increase in price.

Some USDA laboratories offer three degrees of print contrast: "soft" for mapping, "normal" for general use, and "contrast" for timber survey work. The contrast of aerial prints should be specified if a choice is available. The photograph should present maximum tonal differences between timber types without loss of image detail in light and dark areas. Although contrast is limited primarily by the quality of the original exposure, new electronic printing devices get excellent contrast from all but the poorest negatives.

Ordering Agricultural Stabilization and Conservation Service photography.—Photo index sheets or index mosaics, showing the relative positions of all individual photographs within a given county (fig. 3), can be examined at local offices of the Agricultural Stabilization and Conservation Service or the Soil Conservation Service. The number of index sheets per county varies from one to six or more. Foresters working regularly with aerial photographs may want to purchase a set of index sheets for areas where their work is concentrated.

To decide which photographs to order, outline the desired area on the photo index. Include all photographs which overlap this area, partially or completely. Prints are ordered by county symbol, roll number, and exposure number (fig. 1). Other items to specify are:

Date of photography—appears in upper left corner of each print.

Scale—such as 1:20,000 or 1,667 feet per inch.

Reproduction—such as 9- by 9-inch contact prints, double-weight, semimatte paper, with "contrast" finish.

Figure 3.—Portion of an aerial photo index sheet issued by the U.S. Department of Agriculture. Prints are lapped in mosaic fashion to form a composite picture of the county. The serpentine white line indicates that the county boundary is a river.

Photographs of the following States should be ordered from:

Western Laboratory
Aerial Photography Division
Agricultral Stabilization and Conservation Service
U.S. Department of Agriculture
2505 Parley's Way
Salt Lake City, Utah 84109

Arizona	Louisiana	Oklahoma
Arkansas	Minnesota	Oregon
California	Montana	South Dakota
Colorado	Nebraska	Texas
Hawaii	Nevada	Utah
Idaho	New Mexico	Washington
Kansas	North Dakota	Wyoming

Photography of Alaska and Vermont is not available through the ASCS. Photographs of the remaining States should be ordered from:

Eastern Laboratory
Aerial Photography Division
Agricultural Stabilization and Conservation Service
U.S. Department of Agriculture
45 South French Broad Avenue
Asheville, N.C. 28802

Alabama	Maine	North Carolina
Connecticut	Maryland	Ohio
Delaware	Massachusetts	Pennsylvania
Florida	Michigan	Rhode Island
Georgia	Mississippi	South Carolina
Illinois	Missouri	Tennessee
Indiana	New Hampshire	Virginia
Iowa	New Jersey	West Virginia
Kentucky	New York	Wisconsin

Photo index sheets, usually at a scale of 1 inch per mile, cost $2.50 for a sheet 20 by 24 inches. Prices for 9- by 9-inch contact prints, untrimmed and on single- or double-weight paper, are as follows:

Quantity	*Price per print*
First 25	$1.25
Over 25	.90

Contact prints on waterproof (low-shrink) paper are available at an additional 50 cents per print. Quantity prices apply only when an order is shipped to one address. Enlargements are available at four scales ranging from 1:15,840 on prints 14 by 14 inches to 1:4,800 on prints 40 by 40 inches. Prices range from about $2.50 to $8.00 per print.

These prices are as of Oct. 1968, but are subject to revision periodically. Payment must be made in advance, preferably by money order, and 6 to 8 weeks should be allowed for delivery.

Ordering Soil Conservation Service photography.—Some areas of the United States, notably counties bordering the Atlantic Ocean, are not covered by ASCS photography. In some instances, photo coverage of these areas may be purchased from:

Soil Conservation Service
Cartographic Division
U.S. Department of Agriculture
Hyattsville, Md. 20251

Ordering Forest Service photography.—Aerial photographs of the National Forests are available at scales of 1:15,840 (1,320 feet per inch) or 1:12,000 (1,000 feet per inch). Coverage includes the Chugach and part of the Tongass National Forests in Alaska, but does not include Hawaii. Some photographs are on infrared film. The prices quoted for ASCS coverage will generally apply to the Forest Service.

Forest Service photography of Eastern United States may be ordered from:

Chief, Forest Service
U.S. Department of Agriculture
Washington, D.C. 20250

Photographic coverage of Western United States (Forest Service, Regions 1–6 and 10) is obtained through the appropriate Regional Forester as follows:

Region	*Address*
1	Federal Building, Missoula, Mont., 59801
2	Federal Center, Building 85, Denver, Colo., 80225
3	Federal Building, 517 Gold Ave. SW., Albuquerque, N. Mex., 87101
4	Forest Service Building, Ogden, Utah, 84403
5	630 Sansome St., San Francisco, Calif., 94111
6	P.O. Box 3623, Portland, Oreg., 97208
10	Regional Forester, U.S. Forest Service, P.O. Box 1628, Juneau, Alaska, 99801

PREPARING PHOTOGRAPHS FOR STEREO-VIEWING

Equipment Needed

Equipment considered essential by one interpreter may be of limited use to another; nevertheless, the forester who anticipates a continued use of aerial photographs will probably find the following list closely approximates his minimum needs.

Lens stereoscope, folding pocket type.
Parallax bar or parallax wedge for measuring object heights.
Engineer's scale, graduated to 0.02 inch.
Tree crown-density scale.
Tree crown-diameter scale.
Dot grids for acreage determination.
China-marking pencils for writing on photographs.
Carbon tetrachloride and cotton for cleaning photographs.
Drafting instruments, triangles, and drafting tape.
Needles for point-pricking.
Tracing table.
Magnetic or spring-clipboard for holding stereo-pairs.
Proportional dividers.

367-547 O—69—— 2

If purchased with discretion, the items can be obtained for less than $250. For a price list of photo interpretation aids available from the Forest Service, write to the Division of Engineering, Forest Service, U.S. Department of Agriculture, Washington, D.C. 20250.

Many foresters will already own drafting instruments, dot grids, and pocket stereoscopes. A satisfactory tracing table can be improvised by installing a uniform light source under a glass surface. Fluorescent tubes are better than incandescent bulbs because they produce less heat. A sheet of frosted cellulose acetate between two pieces of ordinary single-weight glass serves well when special frosted glass is not available.

If the forester uses aerial photographs regularly and becomes adept in interpretation and mapping, he may wish to acquire more expensive equipment, such as a mirror stereoscope, vertical sketchmaster, reflecting projector, or radial plotting devices. The *Manual of Photogrammetry* (*1*) contains information on such equipment.

Preparing the Photographs

Photographic flights are planned so that prints will overlap about 60 percent in the line of flight and about 30 percent between flight strips. For effective stereo-viewing, prints must be trimmed to the nominal 9- by 9-inch size, preserving the four fiducial marks at the midpoint of each of the edges (fig. 1). Then:

1. *Locate the principal point (PP) or center of each photograph.* Aline opposite sets of fiducial marks with a straightedge or triangle. Draw a cross at the center with a wedge-pointed pencil, and make a fine needle hole at the intersection.
2. *Locate the conjugate principal points (CPP's) on each photograph*—the points that correspond to PP's of adjacent photographs. Adjust the stereoscope until distance between centers of lenses corresponds with interpupillary distance (usually about 2.5 inches). Arrange the first two photographs of a given flight line so that corresponding gross features overlap. Shadows should be toward the observer; if they fall away from the viewer there is a tendency to see relief in reverse. Clip down one photograph. Move adjacent photograph in direction of line of flight until corresponding images on each print are about 2.2 inches apart. Place lens stereoscope over prints *parallel to line of flight* so that the left-hand lens is over the left photograph and the right-hand lens is over the same image on the right photograph. The area around the PP will be seen as a three-dimensional image. The movable photograph should then be fastened down. While viewing this area through the stereoscope, place a needle in the same area on the adjacent photograph until it appears to fall precisely in the hole pricked for the PP. This locates the CPP (fig. 1), though a monocular check should be made before the point is permanently marked. Repeat for all photographs; each will then have one PP and two CPP's except that prints falling at the ends of the flight lines will have only one CPP. Ink a 0.2-inch diameter circle around each PP and CPP (fig. 1).
3. *Locate the flight lines on each print by alining the PP's and CPP's.* Connect the edges of the alined circles with a fine ink line (fig. 1). Because of lateral shifting of the photographic plane in flight, a straight line will rarely pass through the PP and *both* CPP's on a given print.
4. *Determine the photo base length for each stereo-overlap* by averaging the distance between the PP and CPP on one print and the corresponding distance on the overlapping print. Measure to the nearest 0.02 inch and record on the back of each overlap. There will be two average base lengths for each print, i.e., one for each set of overlapping flight lines.

Alining prints for stereoscopic study.—A print is selected and clipped down with shadows toward the viewer. The adjacent print is placed with its CPP 2.2 inches from the corresponding PP on the first print. With flight lines superimposed, the second print is positioned and clipped down. The stereoscope is placed with its long axis parallel to the flight line and with the lenses over corresponding images. In this way an overlapping strip 2.2 inches wide and 9 inches long can be viewed by moving the stereoscope up and down the overlap area (fig. 4).

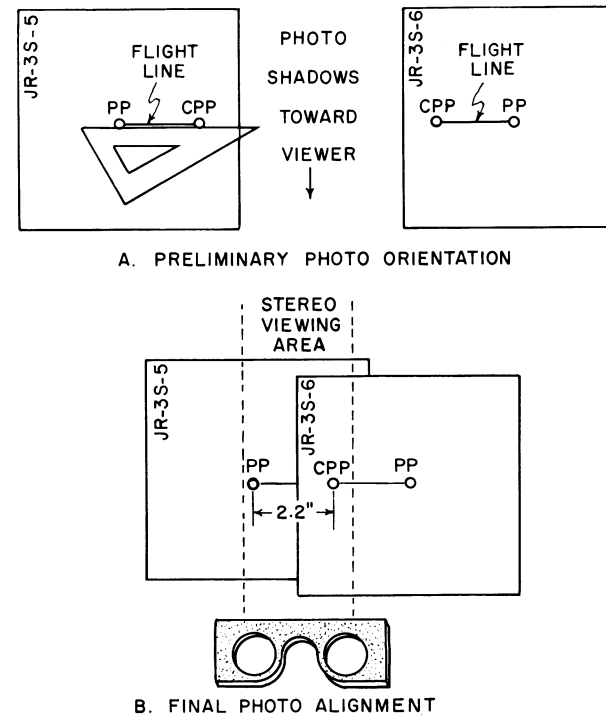

***Figure 4.*—Method of alining 9- by 9-inch contact prints for viewing with a lens stereoscope. Compare this diagram with figure 1.**

While the photos are still clipped down, the prints can be flipped into reverse position with the opposite photo on top. This presents another area of the overlap for stereo-viewing. To study the narrow strip between, the edge of one print must be curled upward or downward and the stereoscope moved parallel to the flight line until the "hidden area" comes into view (fig. 5).

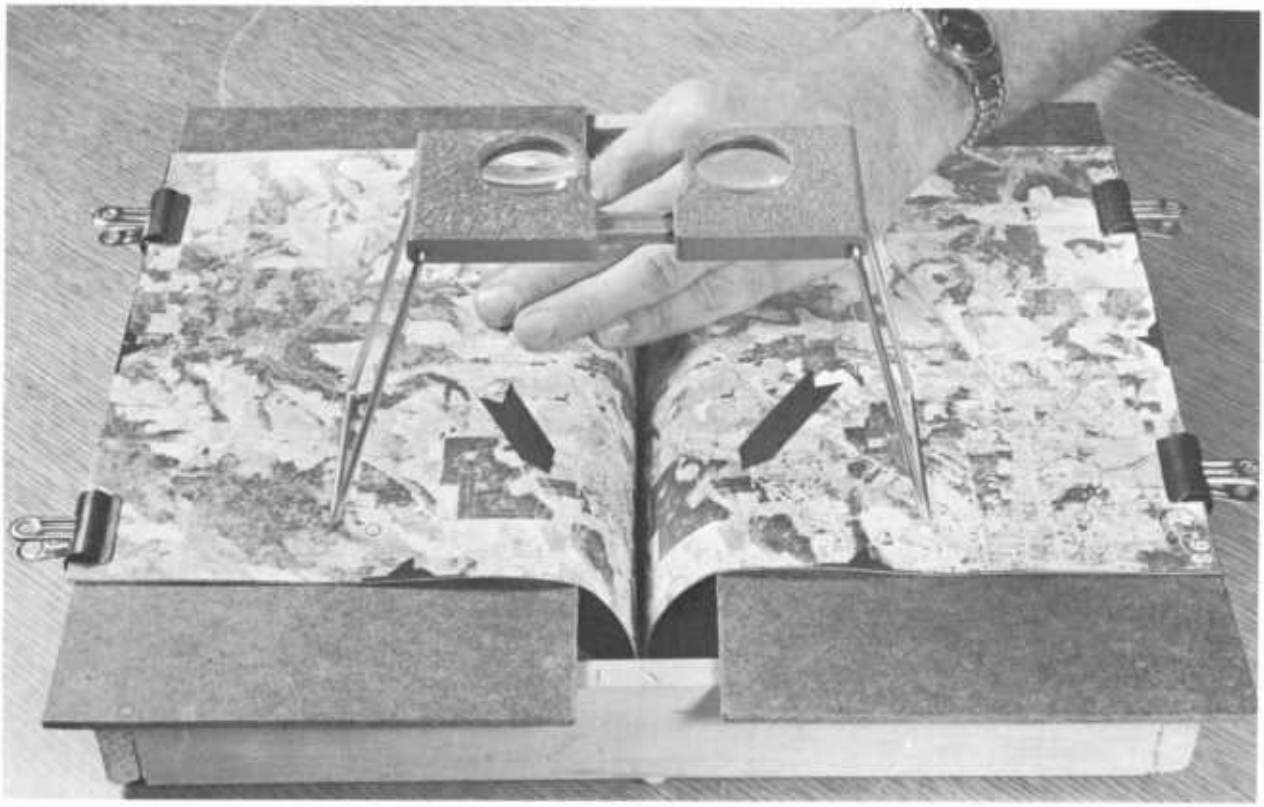

Figure 5.—**Slotted clip board for viewing the "hidden area" of overlapping contact prints with a lens stereoscope. The area indicated by arrows cannot be stereoscopically studied when prints are lapped as in figures 1 and 4.**

PHOTO SCALE, BEARINGS, AND DISTANCES

The vertical aerial photograph presents a true record of angles, but measures of horizontal distances vary widely with changes in ground elevations and flight altitudes. The nominal scale (as 1:20,000) is representative only of the datum, an imaginary plane passing through a specified ground elevation above sea level. Calculation of the average photo scale will increase the accuracy of subsequent photo measurements.

Aerial cameras in common use have focal lengths of 6, 8.25, or 12 inches (0.5, 0.6875, or 1.0 ft.). This information, with the altitude of the aircraft above ground datum, makes it possible to determine the representative fraction (RF) or natural scale:

$$RF=\frac{\text{Focal length (ft.)}}{\text{Flying height above ground (ft.)}}$$

The height of the aircraft is rarely known to the interpreter, however, and photo scale is more often calculated by this proportion:

$$RF=\left[\frac{\text{Photographic distance between two points (ft.)}}{\text{Ground or map distance between same points (ft.)}}\right]$$

Determining scale from ground measurements.—Select two points on opposite sides of the print so that a line connecting them passes near the PP. If the points are approximately equidistant from the PP, the effect of photographic tilt will be minimized. (Tilt results when the camera axis deviates from the vertical at the instant of exposure. It is often present, but generally not enough to be readily noticed.) Points must be easily identifiable on the ground so that the distance between them can be precisely measured. Gas and power line rights-of-way, highways, and railroads offer clearings where ground distances can be quickly chained. It is not necessary to calculate the scale of every photograph in a flight

strip. In hilly terrain, every third or fifth print may be used; in flat topography, every tenth or twentieth. Scales of intervening photographs can be obtained by interpolation.

Office checks of photo scale.—Scale determination from ground measurements is laborious and expensive; hence other methods should be used wherever possible. If a U.S. Geological Survey quadrangle sheet is available, the map distance can be measured and used in the formula, provided the same distance can be identified for photo measurement (fig. 6).

Another alternative is presented in areas of flat terrain where General Land Office subdivisions of sections, quarter-sections, and forties are visible on the photographs. Since the lengths of these subdivisions will be known, they can also be used as ground distances. A given section may rarely be exactly 5,280 feet on a side, but determining scale by this method is more accurate than accepting the nominal scale.

Compass bearings and distances.—Although flight lines usually run north-south or east-west, few photographs are oriented exactly with the cardinal directions. For this reason, a reference line must be located before bearings can be determined. The method described is used by field teams on the U.S. Forest Survey:

1. Select a straight-line feature such as a highway, section line, or field edge and determine its bearing. Draw this reference line on the photograph, extend it as necessary, and record the bearing (fig. 7).

Figure 6.—Determination of photo scale from a U.S. Geological Survey map. Map scale is 1:24,000 or 2,000 feet per inch. Map distance between X and Y is 2.00 inches, or 4,000 feet on the ground. Photo distance is 4.80 inches. Thus the photo scale is $4.80 \div 4{,}000 \times 12$, or 1:10,000. (Courtesy of Abrams Aerial Survey Corporation.)

2. Pick a point of beginning (PB) from which the line of approach to a field location will be run. This should be some feature visible on both photograph and ground, such as a fence corner, barn, road intersection, or stream fork. Draw a line on the photograph from the PB to the location, and extend until it intersects the reference line. Measure the angle between the two lines with a protractor and determine the bearing of the line of approach.

3. Measure the distance between the PB and the field location to the nearest 0.01 inch and convert to feet or chains at the calculated photo scale. At a scale of 1:20,000, a measure of 0.01 inch equals 16.67 feet or about 25 links. In figure 7, the distance from PB to the center of the circular field plot is 1.15 inches, or about 29 chains. Common scale conversions are given in table 1.

TABLE 1.—*Scale conversions for vertical aerial photographs* [1]

Representative fraction (scale)	Feet per inch	Chains per inch	Inches per mile	Acres per square inch	Square miles per square inch
(1)	(2)	(3)	(4)	(5)	(6)
1:7,920	660.00	10.00	8.00	10.00	0.0156
1:8,000	666.67	10.10	7.92	10.20	.0159

1:9,600	800.00	12.12	6.60	14.69	.0230
1:10,000	833.33	12.63	6.34	15.94	.0249
1:10,800	900.00	13.64	5.87	18.60	.0291
1:12,000	1,000.00	15.15	5.28	22.96	.0359
1:13,200	1,100.00	16.67	4.80	27.78	.0434
1:14,400	1,200.00	18.18	4.40	33.06	.0517
1:15,000	1,250.00	18.94	4.22	35.87	.0560
1:15,600	1,300.00	19.70	4.06	38.80	.0606
1:15,840	1,320.00	20.00	4.00	40.00	.0625
1:16,000	1,333.33	20.20	3.96	40.81	.0638
1:16,800	1,400.00	21.21	3.77	45.00	.0703
1:18,000	1,500.00	22.73	3.52	51.65	.0807
1:19,200	1,600.00	24.24	3.30	58.77	.0918
1:20,000	1,666.67	25.25	3.17	63.77	.0996
1:20,400	1,700.00	25.76	3.11	66.34	.1037
1:21,120	1,760.00	26.67	3.00	71.11	.1111
1:21,600	1,800.00	27.27	2.93	74.38	.1162
1:22,800	1,900.00	28.79	2.78	82.87	.1295
1:24,000	2,000.00	30.30	2.64	91.83	.1435
1:25,000	2,083.33	31.57	2.53	99.64	.1557
1:31,680	2,640.00	40.00	2.00	160.00	.2500
Method of calculation	$\frac{RFD}{12}$	$\frac{RFD}{792}$	$\frac{63,360}{RFD}$	$\frac{(RFD)^2}{6,272,640}$	$\frac{\text{Acres/sq. in.}}{640}$

[1] Conversions for scales not shown can be made from the relationships listed at the bottom of each column. With the scale of 1:7,920 as an example (column 1, line 1), the number of feet per inch is computed by dividing the representative fraction denominator (RFD) by 12 (number of inches per foot). Thus, 7,920÷12=660 feet per inch (column 2). By dividing the RFD by 792 (inches per chain), the number of chains per inch is derived (column 3). Other calculations can be made similarly. Under column 4, the figure 63,360 represents the number of inches in one mile; in column 5, the figure 6,272,640 is the number of square inches in one acre; and in column 6, the number 640 is acres per square mile.

IDENTIFYING FOREST TYPES AND TREE SPECIES

Forest types and tree species can often be delineated with greater accuracy and lower cost on aerial photographs than by ground methods. The degree to which species groups can be recognized depends on the quality, scale, and season of photography; the type of film used; and the interpreter's training. A general knowledge of forest associations and plant ecology is helpful, but field experience in the specific area to be mapped is far more valuable.

A generalized map of forest regions in the United States is shown in figure 8. The tree species listed provide the first step in identification, i.e., the elimination of those cover types not likely to occur in a given locality. The second step, heavily dependent on a knowledge of local

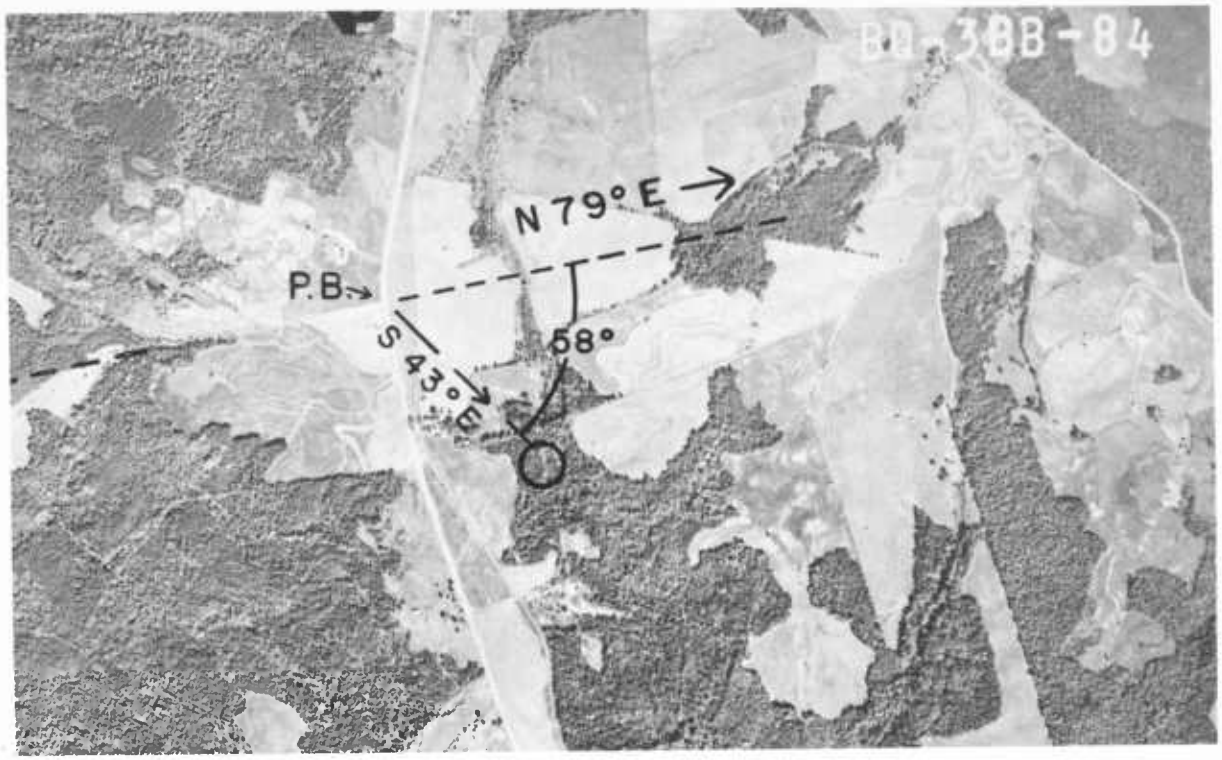

Figure 7.—**Determination of compass bearing and distance to a field plot on a USDA contact print. Scale is 1,667 feet per inch.**

vegetation, is to establish which forest types may be encountered in the area to be mapped.

Recognition of an individual species, often feasible only on large-scale photography, is normally the culmination of intensive study. Obviously the forest interpreter must be familiar with branching patterns and crown shapes of all important species in his region. Mature conifers in sparsely stocked stands can often be recognized on 1:20,000 USDA photography by the configuration of their crown shadows falling on level ground (fig. 9). Studying oblique photographs of trees has been helpful to many foresters.

Recognition of species on vertical photographs also requires a familiarity with tree crowns as seen in overhead views (fig. 10). While overhead crown characteristics are not always apparent on 1:12,000 to 1:20,000 photographs, they can be highly useful on large-scale stereograms. Photo scales as large as 50 feet per inch have been utilized for tree species identifications in Canada (*16*, *20*).

Aside from shadows, crown shapes, and branching patterns, the features to consider in identifying tree species are photographic texture (smoothness or coarseness of images), tonal contrast, relative sizes of tree images at a given photo scale, and topographic location or site. Most of these are rather weak clues when observed singly, yet together they may be the final link in identification by elimination.

For some parts of the United States and Canada, vegetation keys are available aids in tree species recognition. Keys are useful for training new interpreters and for reference by more experienced personnel. Depending on the method of presenting diagnostic features, photo interpretation keys may be grouped into two general classes: *selective* keys and *elimination* keys. Selective keys are usually illustrations and descriptions of trees in a specific region, e.g., pines of Florida. They are organized for comparative use; the interpreter merely selects the key example that most nearly coincides with the forest stand he must identify. By contrast, elimination keys require the user to follow a step-by-step procedure, working from the general to the specific. One of the more common forms of elimination keys is the dichotomous type. Here the interpreter must continually select one of two contrasting alternatives until he progressively eliminates all but the item being sought.

A sample elimination key for identifying northern conifers is reproduced here. It may be used to identify tree species pictured in the large-scale stereograms in figure 11. In original form, this Canadian key had additional descriptive materials and illustrations such as those shown in figures 9 and 10 (*16*).

Vegetation keys are most easily constructed for northern and western forests where conifers predominate, because there are relatively few species to be considered and crown patterns are rather distinctive for each important group. By con-

trast, few if any, reliable keys are available for the highly variable hardwood forests of Southern and Eastern United States.

While the scope of this handbook does not permit a detailed treatment of all important forest types throughout the United States and Canada, examples are given in figures 12 through 18.

Key to the Northern Conifers [3]

1. Crowns small, or if large then definitely cone-shaped.
   2. Crown broadly conical, usually rounded tip, branches not prominent ---------- cedar
   2. Crowns have a pointed top, or coarse branching, or both.
      —crowns narrow, often cylindrical, trees frequently grow in swamps------ swamp type black spruce
      —crowns conical, deciduous, very light-toned in fall, usually associated with black spruce-------- tamarack
      —crowns narrowly conical, very symmetrical, top pointed, branches less prominent than in white spruce ---------- balsam fir
      —crowns narrowly conical, top often appears obtuse on photograph (except northern white spruce), branches more prominent than in balsam fir ---------- white spruce, black spruce (except swamp type)
      —crowns irregular, with pointed top, has thinner foliage and smoother texture than spruce and balsam fir---------- jack pine
1. Crowns large and spreading, not narrowly conical, top often not well defined.
   3. Crowns very dense, irregular or broadly conical.
      4. Individual branches very prominent, crown usually irregular ---------- white pine
      4. Individual branches rarely very prominent, crown usually conical ---------- eastern hemlock
   3. Crowns open, oval (circular in plain view)---------- red pine

MAPPING FROM AERIAL PHOTOGRAPHS

Type maps are no longer considered essential by all foresters, but at times their cost may be justified. A general ownership map showing principal roads, streams, forest types, and condition classes may be desired for management planning and illustrative purposes. Also, in making a photo-controlled ground cruise where precise forest-area estimates are required, it may be necessary to measure stand areas on controlled maps of known scale rather than directly on contact prints. This is particularly important where topography causes wide variation in photo scales.

The wise interpreter will delineate only those types that he can consistently recognize. For maximum accuracy, type lines should be drawn under the stereoscope. As lines made with a china-marking pencil are easily removed with carbon tetrachloride or benzene, this method is recommended for preliminary work. Water-soluble ink is also suitable. Permanent markings can be made with drawing ink after types have been verified by ground reconnaissance.

Uncontrolled maps.—Where area measurement is not critical, simple uncontrolled type maps can be prepared at photo scale by direct tracing. Tract boundaries are drawn within the "effective area" [4] of alternate prints in each flight strip. Photographs are interpreted under the stereoscope, and all types and planimetric data are outlined. The detail is then traced onto frosted acetate or vellum, from one annotated print at a time. If boundaries are accurately drawn on interpreted prints to include all of the tract without duplication, the traced data from adjoining prints should match up without difficulty. To assure standardization in type recognition, it is desirable to have one man perform all interpretation work.

Uncontrolled maps are no more accurate for area measurement than the photographs from which they were prepared, but they may suffice for management plans and illustrations. Where flat terrain predominates, average photo scales vary only slightly and tracings may approach the accuracy of controlled maps.

Controlled maps.—Base maps of uniform scale may be required for photo-controlled ground cruises, as precise measures of forest area by type and stand size are essential for accurate volume estimates. In flat terrain, average photo scale can be determined and acreages measured directly on contact prints, but in steep topography variations in photo scale require the transfer of forest types to base maps for accurate area measurement. The most common way of adjusting variable photo scales to controlled maps is by constructing "radial line plots" or by preparing plat sheets from field notes of the General Land Office. As construction of a radial line plot is complex and has been ade-

[3] Reproduced by permission of L. Sayn-Wittgenstein, Forest Research Branch, Canada Department of Forestry (*16*).

[4] If 9- by 9-inch photographs with 60-percent endlap and 30-percent sidelap are assumed, alternate photographs will have effective areas of about 7.2 by 6.3 inches.

PRINCIPAL TREES OF THE FOREST REGIONS

NOTE.—The order indicates the relative importance or abundance of the trees

ROCKY MOUNTAIN FOREST

Northern Portion (Northern Idaho and Western Montana):

Lodgepole pine
Douglas-fir
Western larch
Engelmann spruce
Ponderosa pine
Western white pine
Western redcedar
Grand and alpine firs
Western and mountain hemlocks
Whitebark pine
Balsam poplar

Eastern Oregon, Central Idaho, and Eastern Washington:

Ponderosa pine
Douglas-fir
Lodgepole pine
Western larch
Engelmann spruce
Western redcedar
Western hemlock
White, grand, and alpine firs
Western white pine
Oaks and junipers (in Oregon)

Central Montana, Wyoming, and South Dakota:

Lodgepole pine
Douglas-fir
Ponderosa pine
Engelmann spruce
Alpine fir
Limber pine
Aspen and cottonwoods
Rocky Mountain juniper
White spruce

Central Portion (Colorado, Utah, and Nevada):

Lodgepole pine
Engelmann and blue spruces
Alpine and white firs
Douglas-fir
Ponderosa pine
Aspen and cottonwoods
Pinyons
Rocky Mountain and Utah junipers
Bristlecone and limber pines
Mountain-mahogany

Southern Portion (New Mexico and Arizona):

Ponderosa pine
Douglas-fir
White, alpine, and corkbark firs
Engelmann and blue spruces
Pinyons
One-seed, alligator, and Rocky Mountain junipers
Aspen and cottonwoods
Limber, Mexican white, and Arizona pines
Oaks, walnut, sycamore, alder, boxelder
Arizona cypress

PACIFIC COAST FOREST

Northern Portion (Western Washington and Western Oregon):

Douglas-fir
Western hemlock
Grand, noble, and Pacific silver firs
Western redcedar
Sitka and Engelmann spruces
Western white pine
Port Orford cedar and Alaska cedar
Western and alpine larches
Lodgepole pine
Mountain hemlock
Oaks, ashes, maples, birches, alders, cottonwoods, madrone

Southern Portion (California):

Ponderosa and Jeffrey pines
Sugar pine
Redwood and giant sequoia
White, red, grand, and Shasta red firs
California incense-cedar
Douglas-fir
Lodgepole pine
Knobcone and Digger pines
Bigcone-spruce
Monterey and Gowen cypresses
Sierra and California junipers
Singleleaf pinyon
Oaks, buckeye, California-laurel, alder, madrone

SOUTHERN FOREST

Pine Lands:

Shortleaf, loblolly, longleaf, slash, and sand pines
Southern red, black, post, laurel, cherrybark, and willow oaks
Sweetgum
Winged, American, and cedar elms
Black, red, sand, and pignut hickories
Eastern and southern redcedars
Basswoods

Alluvial Bottoms and Swamps:

Sweetgum and tupelos
Water, laurel, live, overcup, Texas, and swamp white oaks
Southern cypress
Pecan, water and swamp hickories
Beech
River birch
Ashes

Alluvial Bottoms and Swamps:

Red and silver maples
Cottonwoods and willows
Sycamore
Hackberry
Honeylocust
Holly
Redbay and sweetbay
Southern magnolia
Pond and spruce pines
Atlantic white-cedar

CENTRAL HARDWOOD FOREST

Northern Portion:

White, black, northern red, scarlet, bur, chestnut, and chinquapin oaks
Shagbark, mockernut, pignut, and bitternut hickories
White, blue, green, and red ashes
American, rock, and slippery elms
Red, sugar, and silver maples
Beech
Pitch, shortleaf, and Virginia pines
Yellow-poplar
Sycamore
Chestnut
Black walnut
Cottonwoods
Hackberry
Black cherry
Basswoods
Ohio buckeye
Eastern redcedar

Southern Portion:

White, post, southern red, blackjack, Shumard, chestnut, swamp chestnut, and pin oaks
Sweetgum and tupelos
Mockernut, pignut, southern shagbark, and shellbark hickories
Shortleaf and Virginia ("scrub") pines
White, blue, and red ashes
Yellow-poplar
Black locust
Elms
Sycamore
Black walnut
Silver and red maples
Beech
Dogwood
Persimmon
Cottonwoods and willows
Eastern redcedar
Osage-orange

Texas Portion:

Post, southern red, and blackjack oaks
Eastern redcedar, Ashe juniper

FLORIDA AND TEXAS FOREST—TROPICAL

Mangrove, false mangrove
Royal and thatch palms; palmettos
Florida yew
Wild figs
Seagrapes ("pigeon plum")
Blolly
Bahama lysiloma ("wild tamarind")
Wild-dilly
Gumbo-limbo
Poisontree
Inkwood
Button-mangrove
False-mastic ("wild olive")
Fishpoison-tree ("Jamaica dogwood")

NORTHERN FOREST

Northern Portion:

Red, black, and white spruces
Balsam fir
Eastern white, red ("Norway"), jack, and pitch pines
Hemlock
Sugar and red maples
Beech
Northern red, white, black, and scarlet oaks
Yellow, paper, sweet, and gray birches
Quaking and bigtooth aspens
Basswoods
Black cherry
American, rock, and slippery elms
White and black ashes
Shagbark and pignut hickories
Butternut
Northern white-cedar
Tamarack

Southern Portion (Appalachian Region):

White, northern red, chestnut, black, and scarlet oaks
Chestnut
Hemlock
Eastern white, shortleaf, pitch, and Virginia ("scrub") pines
Sweet, yellow, and river birches
Basswood
Sugar and red maples
Beech
Red spruce
Fraser fir
Yellow-poplar
Cucumber magnolia
Black walnut and butternut
Black cherry
Pignut, mockernut, and red hickories
Black locust
Tupelos ("blackgums")
Buckeye

ALASKA FOREST

Coast Forest:

Western hemlock (important)
Sitka spruce (important)
Western redcedar
Alaska cedar
Mountain hemlock
Lodgepole pine
Black cottonwood
Red and Sitka alders
Willows

Interior Forest:

White (important) and black spruces
Alaska paper (important) and Kenai birches
Black cottonwood
Balsam poplar
Aspen
Willows
Tamarack

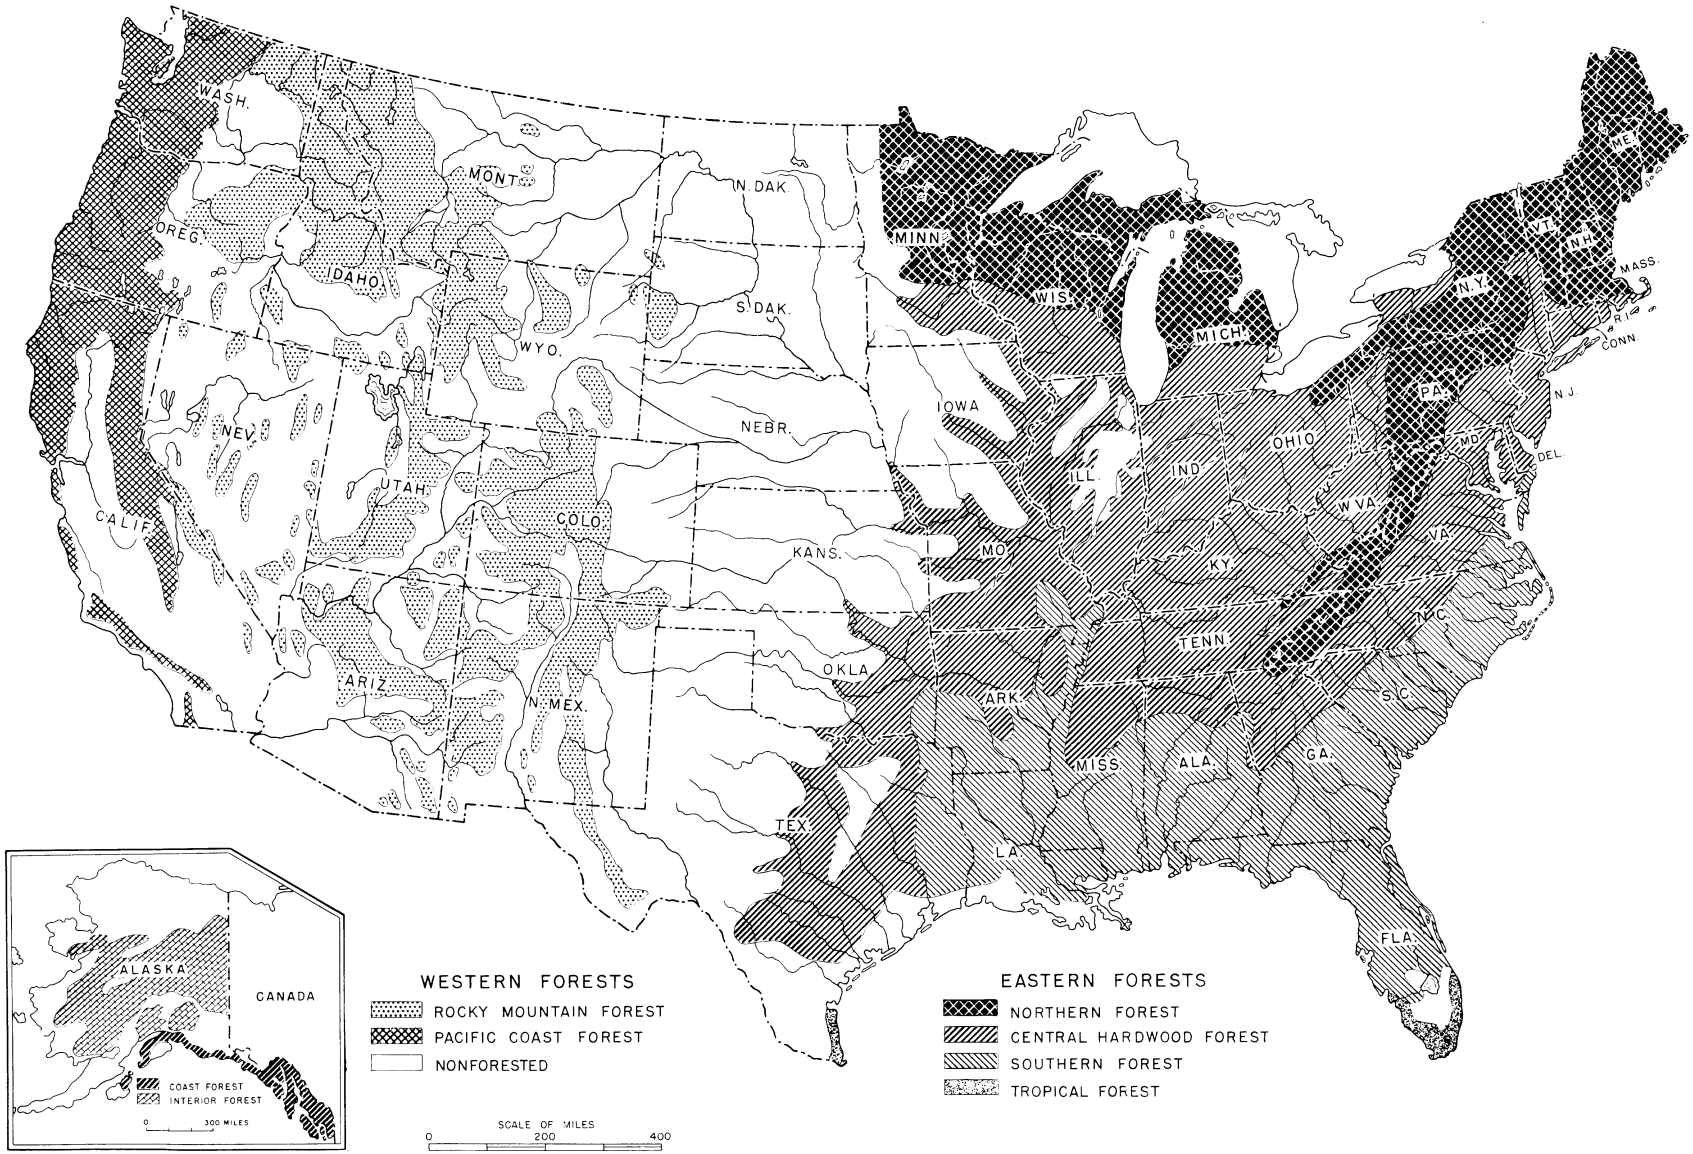

Figure 8.—**Forest regions of the United States.**

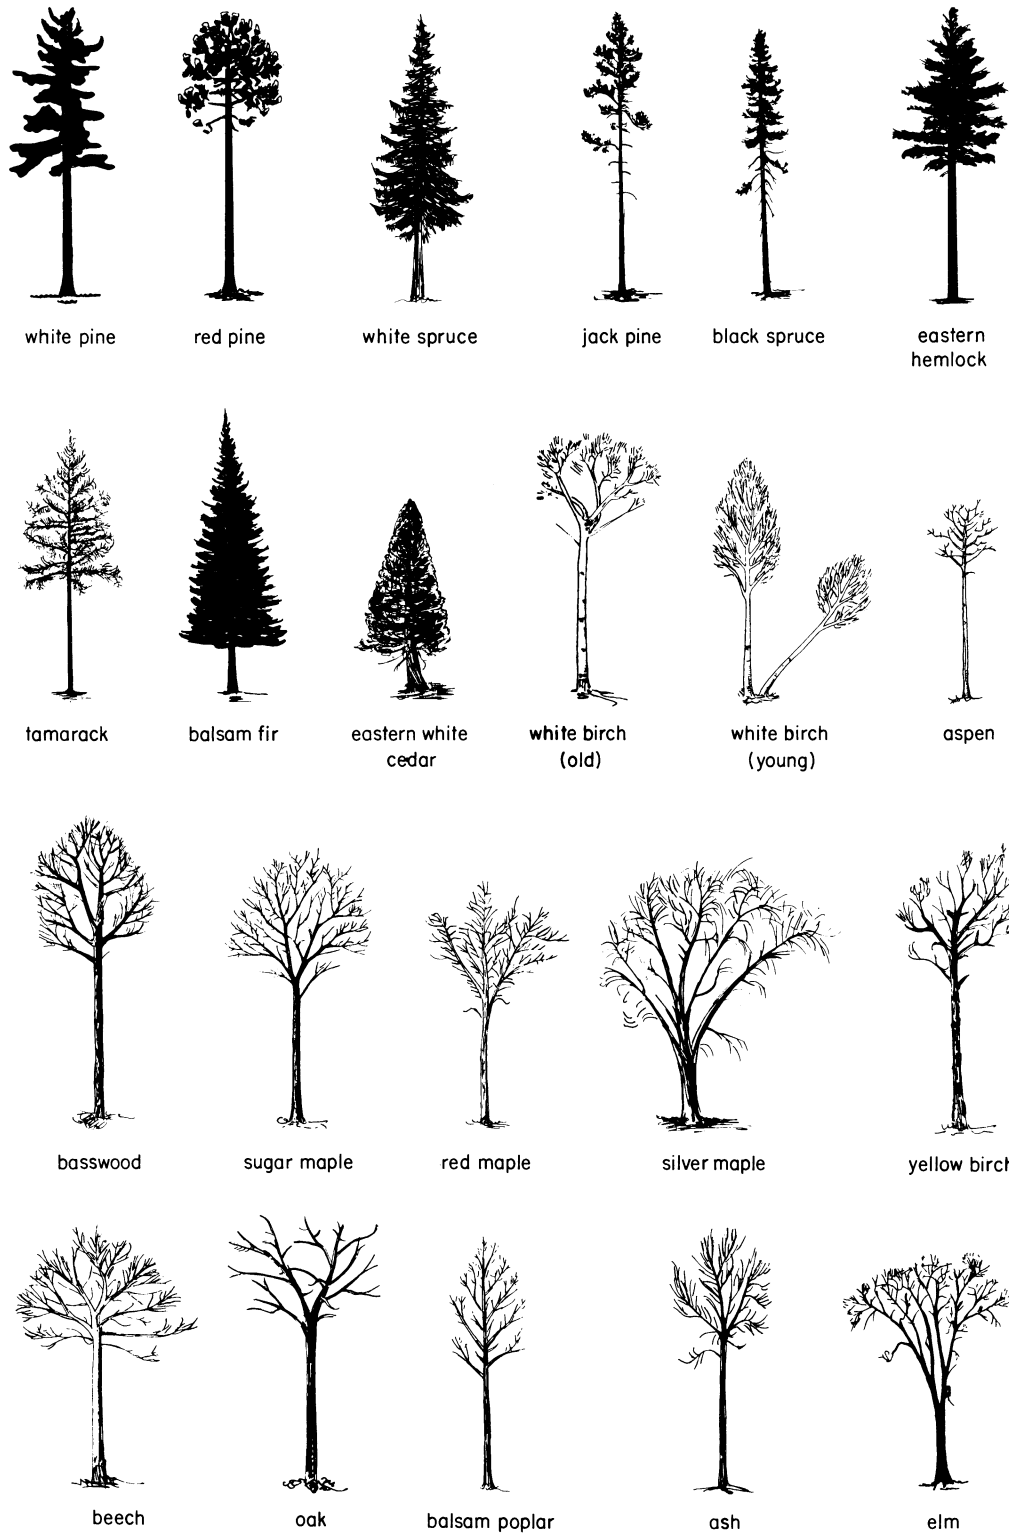

Figure 9.—**Silhouettes of forest trees. When tree shadows fall on level ground, they often permit identification of individual species. (Reprinted by permission of L. Sayn-Wittgenstein, Forest Research Branch, Canada Department of Forestry.)**

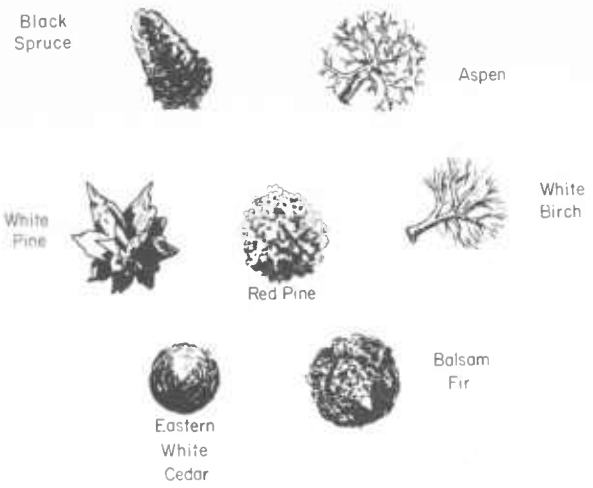

Figure 10.—Vertical views of tree crowns. Compare with stereograms in figure 11. (Reprinted by permission of L. Sayn-Wittgenstein, Forest Research Branch, Canada Department of Forestry.)

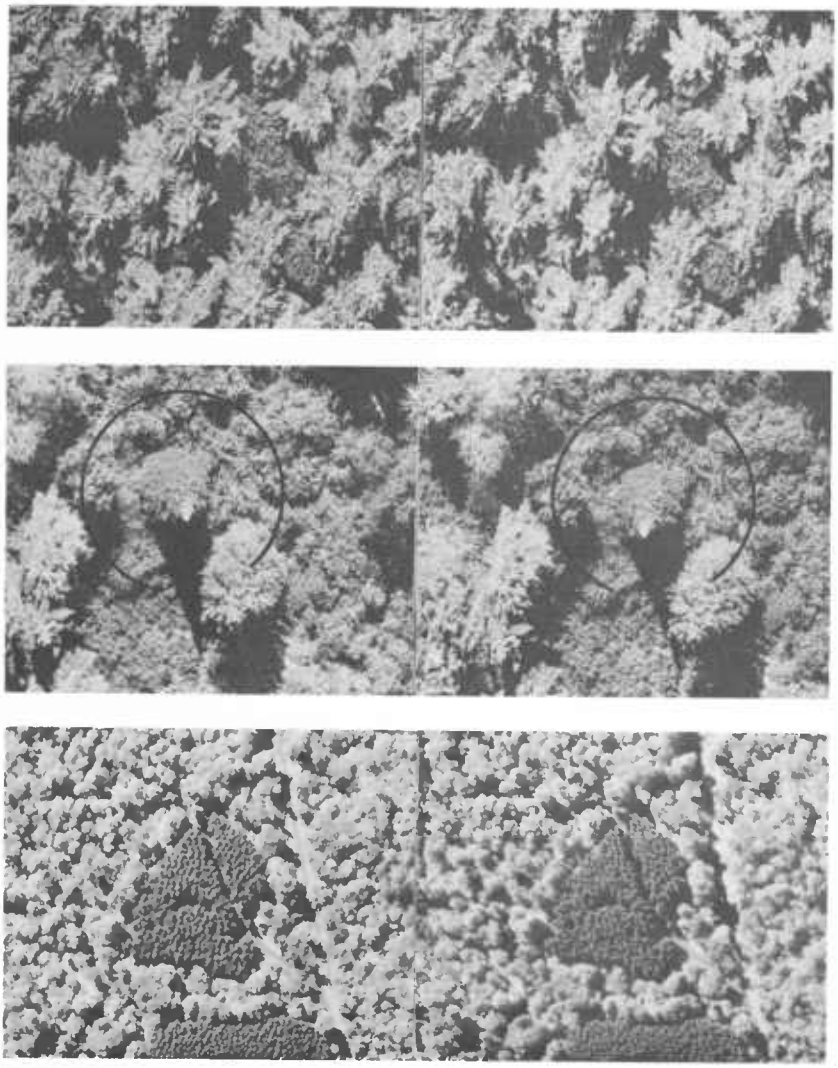

Figure 11.—Large-scale stereograms showing star-shaped white pine crowns (top), cone-shaped balsam fir crowns (center), and a red pine plantation surrounded by a stand of basswood (bottom). The two upper stereograms are on panchromatic film at a scale of 50 feet per inch. The bottom pair is on infrared film at a scale of 330 feet per inch. (Reprinted by permission of L. Sayn-Wittgenstein, Forest Research Branch, Canada Department of Forestry.)

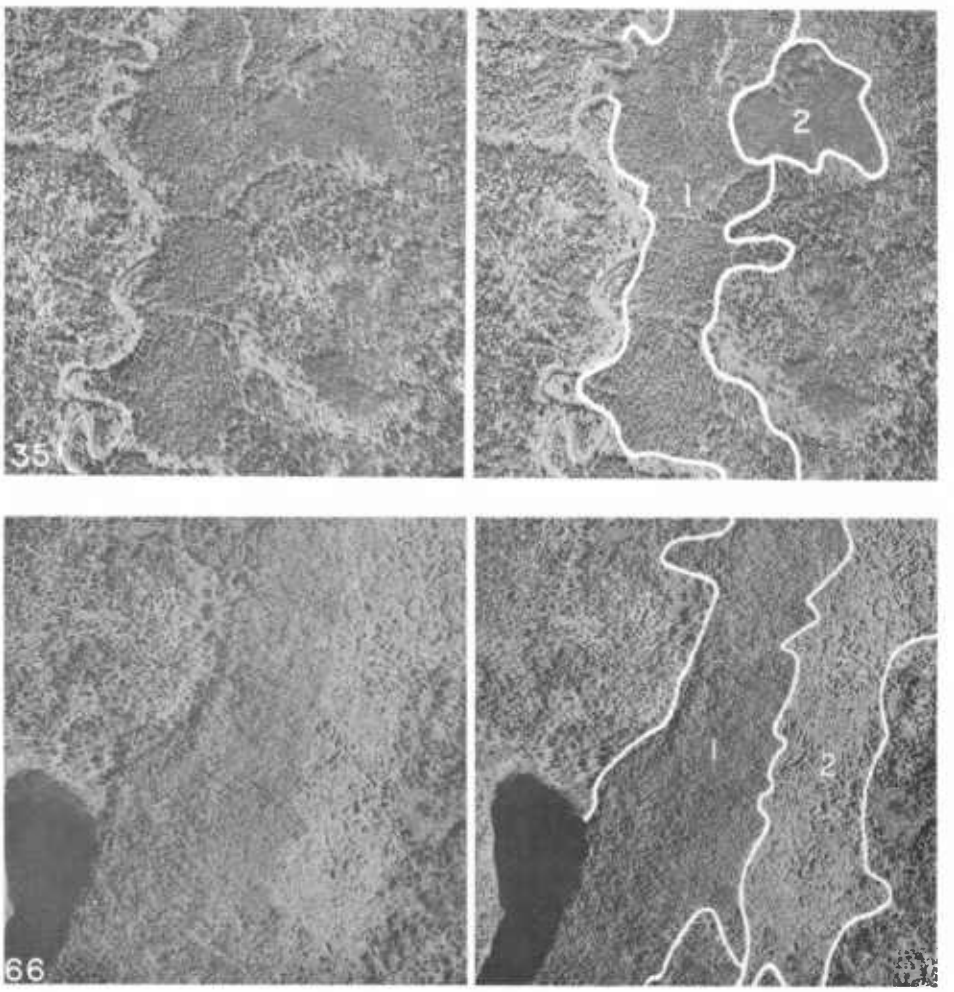

Figure 12.—Summer panchromatic photography in Ontario. In the upper stereogram (No. 35) stand 1 is balsam fir and stand 2 is black spruce. In the lower stereogram (No. 66) stand 1 is aspen-white birch and stand 2 is beech. Scale is 1,320 feet per inch. (Reprinted by permission of V. Zsilinszky, Ontario Department of Lands and Forests, Canada.)

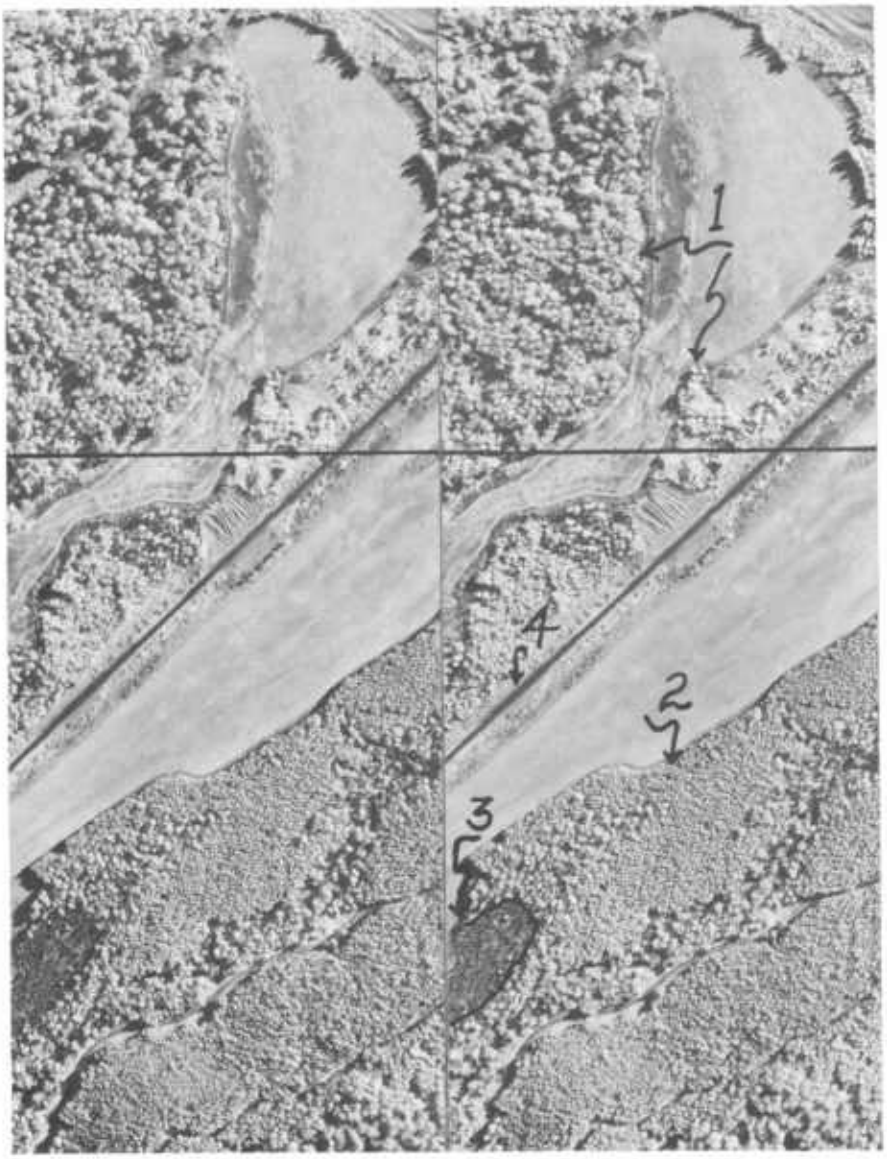

Figure 13.—Infrared stereogram illustrating forest associations in central Alaska. Types are (1) paper birch, (2) aspen, and (3) white spruce. A portion of the Alaska Railroad is shown at (4). Scale is about 420 feet per inch.

Figure 14.—USDA panchromatic stereogram from Del Norte County, Calif. Enclosed trees are primarily redwood, with lesser numbers of Douglas-fir, spruce, and hemlock. Clear stereo-viewing is hindered by the heavy displacement of trees, some of which are 250 to 300 feet tall. Scale is about 1,667 feet per inch.

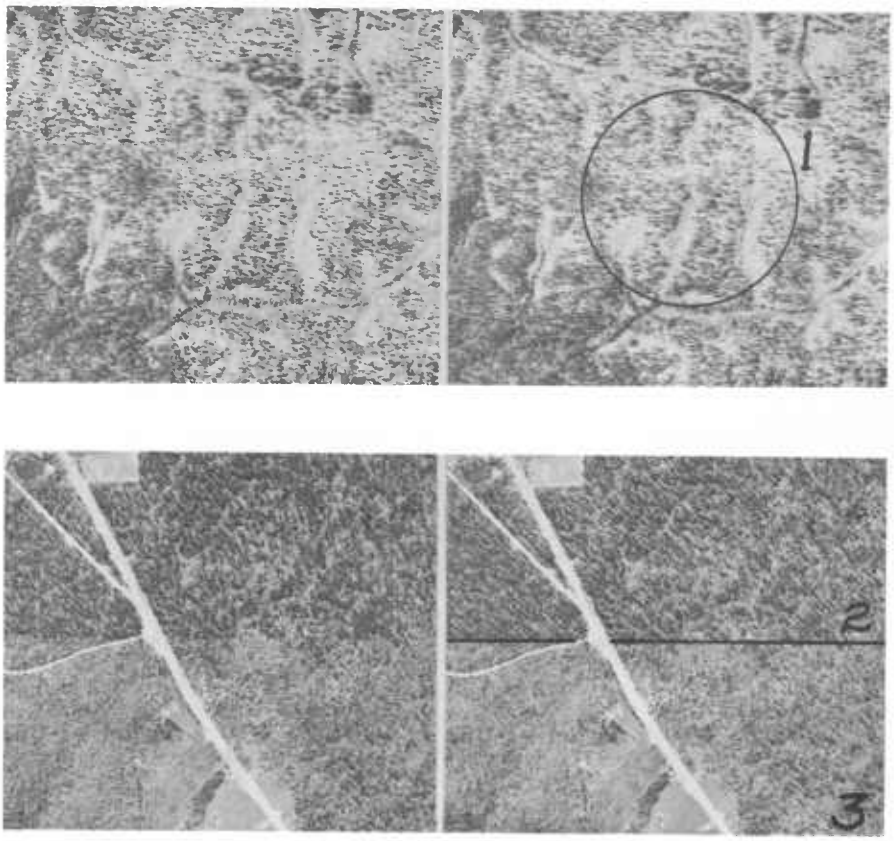

Figure 15.—USDA panchromatic stereograms from Jackson (above) and Clarke Counties, Miss. At (1) is a natural stand of longleaf and slash pines; loblolly-shortleaf pines are pictured at (2) and leafless upland hardwoods at (3). Scale is about 1,667 feet per inch.

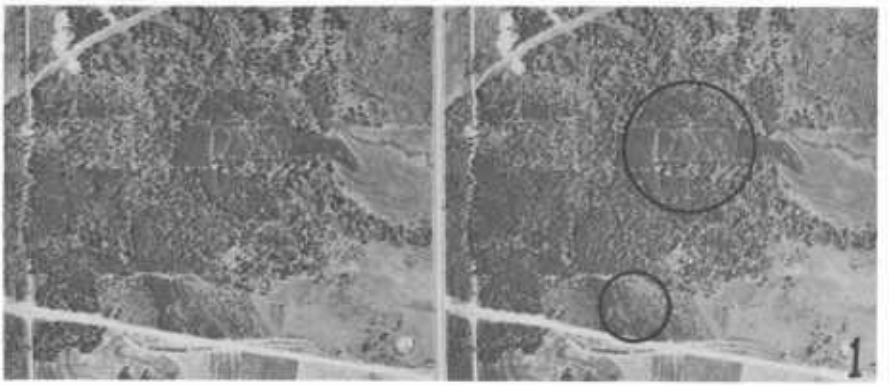

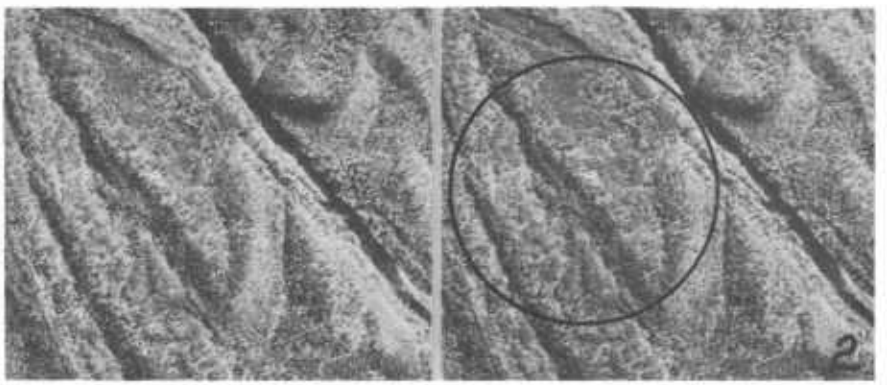

Figure 16.—USDA panchromatic stereograms from Columbia (above) and Sevier Counties, Ark. Two loblolly pine plantations are pictured at (1), while the mountainous terrain at (2) supports a mixture of upland hardwoods and shortleaf pine. Scale is about 1,667 feet per inch.

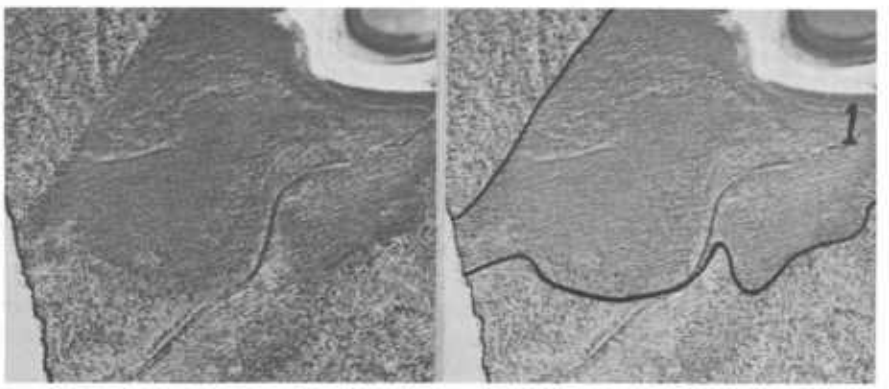

Figure 17.—USDA panchromatic stereograms from Bolivar County, Miss. The fine-textured stand at (1) is willow and cottonwood growing on a recent deposition of sand and silt. At (2) is a stand of bottom-land hardwoods, i.e., oaks, gums, maples, and other wet-site species. Scale is about 1,667 feet per inch.

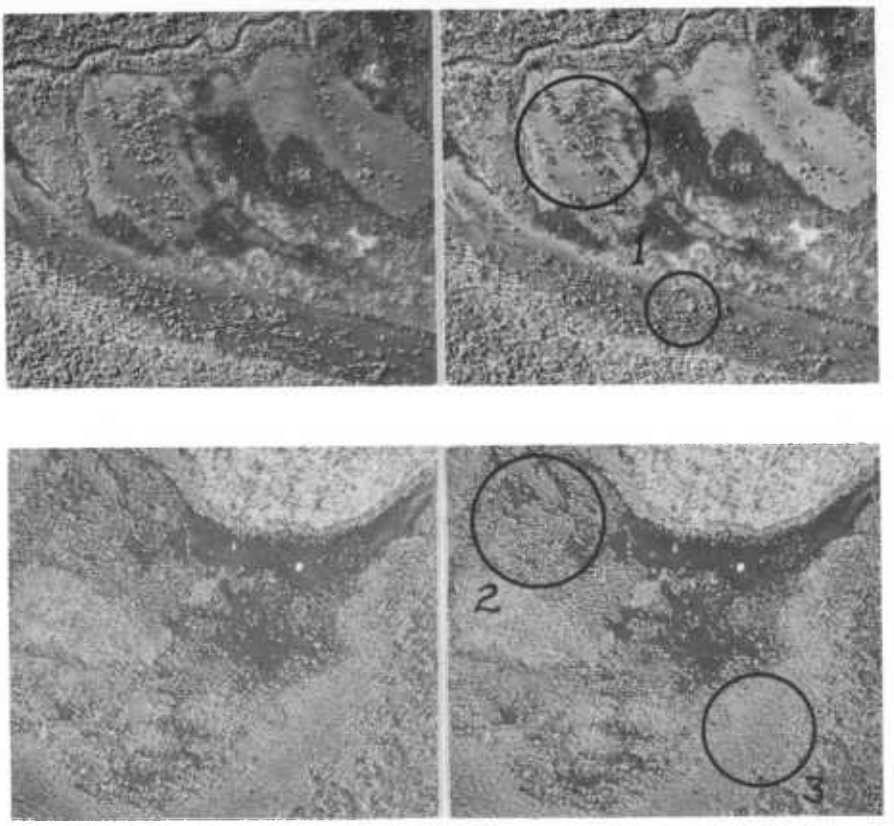

Figure 18.—**USDA panchromatic stereograms from Lafayette County, Ark. Pure stands of southern cypress are shown at (1); the irregular and somewhat star-shaped crowns of this species can be clearly discerned against the water. At (2) is a mixture of cypress and tupelo gum, while a pure stand of tupelo gum is pictured at (3). Scale is about 1,667 feet per inch.**

quately treated in several readily available publications (*1*, *17*, *18*), it will not be reviewed here.

General Land Office (GLO) plats.—Most of the United States west of the Mississippi River and north of the Ohio River, plus Alabama, Mississippi, and portions of Florida, was originally subdivided under the U.S. Public Land Survey. Township, range, and section lines are often visible on aerial photographs. If enough such lines and corners can be identified, GLO plats can be constructed for use as base maps from field notes available at State capitals or county offices. To do this, a GLO plat showing sections, quarter sections, and forties is drawn to average photo scale from field notes. As many as possible of the same lines and corners are pinpointed on the aerial photographs, preferably arranged in a systematic framework throughout the forest property. Ownership maps, county highway maps, and topographic quadrangle sheets may help to identify such corners, but additional points must usually be found by taking the photographs into the field. The accuracy of this method depends upon the number of grid lines and corners which can be pinpointed on the aerial photographs. The technique described is adapted from Johnson (*7*).

When photo interpretation of forest types has been completed, the detail is transferred to the plat, one square of the grid being completed at a time. If the plat and photographs are of the same scale, transfer can be made by direct tracing on a light table; where scales differ, a vertical sketchmaster is recommended (fig. 19). By moving this instrument up or down on its adjustable legs, maps can be drawn at scales of seven-tenths to one and one-half times the scale of the contact print. The sketchmaster accommodates a single, annotated print, which is placed face up on the platform under a large mirror. Photo images are reflected from the large mirror to a semisilvered mirror in the eyepiece housing. The semitransparent eyepiece mirror thus provides a monocular view of the reflected photo image superimposed on the base map. When the grid points on photograph and map have been matched, the transfer of detail becomes a simple procedure (fig. 20).

Topographic and county maps.—Topographic quadrangle sheets and county highway maps are often useful in preparing base maps and identifying features on aerial photographs. When available, 7½-minute quadrangle maps at a scale of 1:24,000 provide excellent base maps, and can be

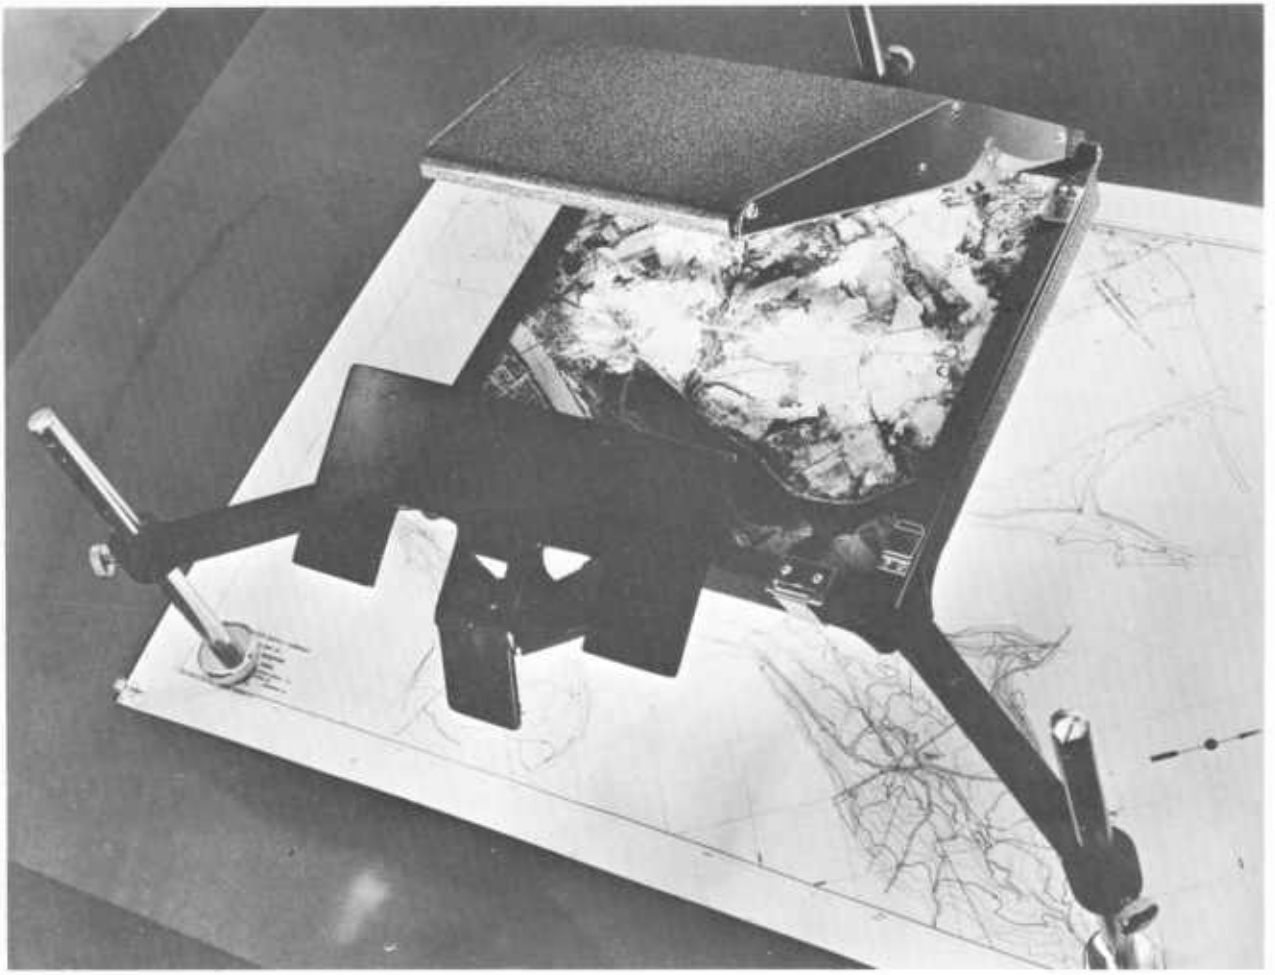

Figure 19.—**Vertical sketchmaster for transferring detail from single contact prints to a base map. A semisilvered eyepiece mirror enables the operator to view photograph and map simultaneously. (Courtesy of Aero Service Corporation.)**

purchased for about 30 cents per copy. Maps for areas west of the Mississippi River, including all of Louisiana and Minnesota, can be purchased from

U.S. Geological Survey
Distribution Section
Federal Center
Denver, Colo. 80225

For areas east of the Mississippi River, including Puerto Rico and the Virgin Islands, maps may be purchased from

U.S. Geological Survey
Distribution Section
Washington, D.C. 20240

Maps of Hawaii may be ordered at either address. All orders must be paid in advance. Other sources of topographic quadrangle maps are the Maps and Surveys Branch of the Tennessee Valley Authority, Chattanooga, Tenn.; the Mississippi River Commission, U.S. Army Corps of Engineers, Vicksburg, Miss.; and the U.S. Coast and Geodetic Survey, Department of Commerce, Washington, D.C.

County maps, usually obtained from State highway departments, may serve as base maps when a high level of accuracy is not required. They show township, range, and section lines, in addition to geographic coordinates (longitude and latitude) to the nearest 5 minutes. They are usually printed at a scale of about one-half inch per mile. Although bearings of section lines are not shown, such maps are more reliable than oversimplified plats showing idealized sections oriented exactly with the cardinal directions. Portions of county maps can be enlarged to photo scale and sections subdivided into quarters or forties by proportionate measurement. These maps may be especially helpful in preparing GLO plats as previously outlined.

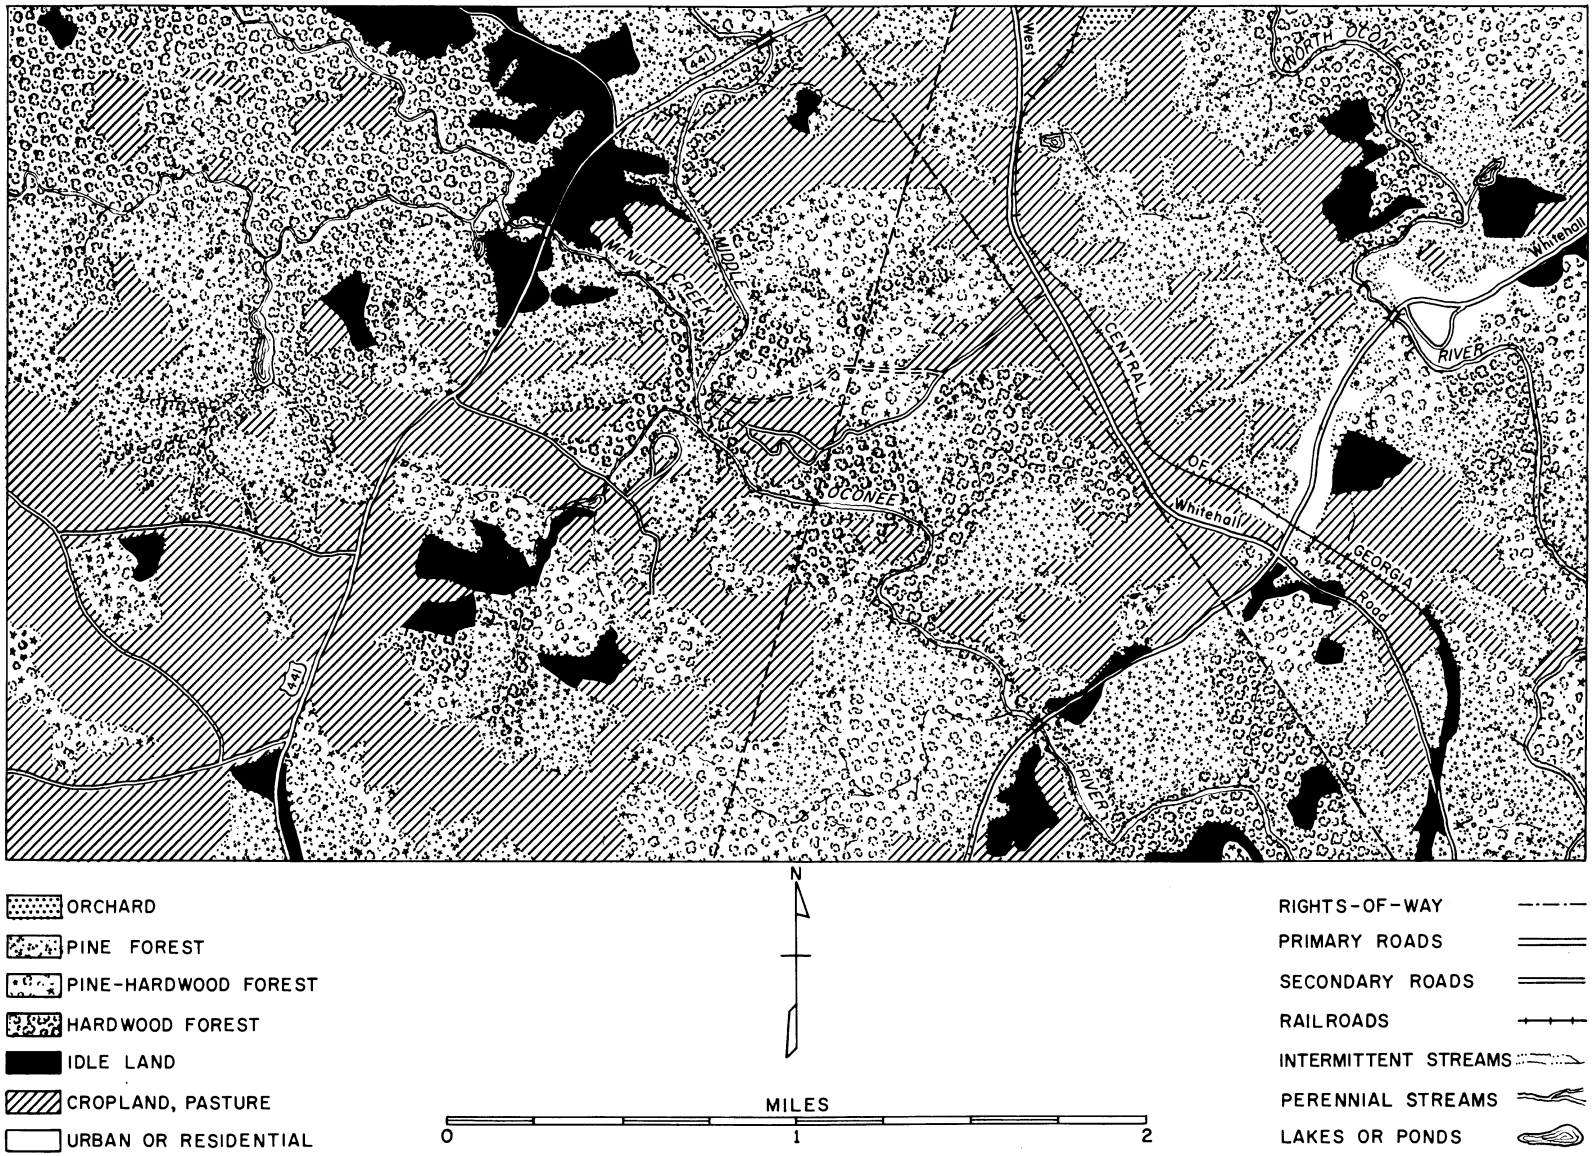

Figure 20.—**Photo mosaic assembled from 1960 USDA prints, and corresponding map compiled with the vertical sketchmaster. The area is in Clarke County, Ga.**

MEASURING AREAS

Both aerial and ground cruising require accurate measurement of forest areas. Photographs offer an inexpensive means of making such determinations. In locations where photo scales are not appreciably altered by topographic changes, areas can be measured directly on contact prints. Greater accuracy is possible if forest types are transferred to controlled base maps before area is determined. This procedure is essential for mountainous terrain. On the other hand, if only relative proportions of the forest types are needed and measurements are limited to the effective areas of contact prints, no bias results from using photographs, even when local relief ranges from 500 to 1,000 feet (*12, 19*). (This statement assumes that, for large tracts, errors in measurement of areas below the datum plane are compensated by errors of a similar magnitude above the datum plane.) Small tracts in rough topography should be measured on controlled maps. Measurement techniques are similar in both cases, so the procedures outlined for measuring area on photographs generally apply to map determinations.

Devices for area measurement.—The principal devices for area measurement are polar planimeters, transects, and dot grids.

The planimeter is relatively expensive and its use somewhat tedious. The pointer is carefully run clockwise around the boundaries of an area two or more times (for an average reading). From the vernier scale, the area is read in square inches and then converted to the desired units, usually acres, on the basis of photo or map scale.

The transect method is analogous to determining forest area by a strip cruise in which the chainage encountered in each forest type is recorded. An engineer's scale is alined on the photographs to cross topography and drainage at approximately right angles. The length of each type along the scale is recorded to the nearest tenth of an inch. Proportions for each type are developed by relating the total measure of that type to the total linear measure. For example, if six equally spaced parallel lines 6 inches long are tallied on a given photograph, the total transect length is 36 inches. If hardwoods are intercepted for a total measure of 7.2 inches, this particular type would be assigned an acreage equivalent to $7.2 \div 36$, or 20 percent of the total area. The transect method is simple and requires a minimum of equipment. For making rough area estimates on photo index sheets, special transparent overlays for location of transect lines can be improvised (*9*).

Use of a dot grid is the preferred method for determining area on aerial photographs. A dot grid is a transparent overlay with dots systematically arranged on a grid pattern. In use, the grid is alined with a straight-line feature to avoid positioning bias, and then dots are tallied for each forest type (fig. 21). Type areas are calculated by proportions: the number of dots on a given type divided by the total number of dots counted yields a percentage value that is multiplied by the total area to obtain the acreage of the type. If total acreage is not known, the number of acres per square inch is determined. This figure is then divided by the number of dots per square inch to find the acreage represented by each dot.

Intensity of dot sampling.—The number of dots that must be counted for a given accuracy depends upon the estimated proportion of the total area occupied by the most important classification to be recognized. For example, suppose area breakdowns are needed for 10 square miles photographed at a scale of 1:15,840. Estimated proportions of each area classification are as follows: forest, 25 percent; agricultural lands, 60 percent; urban areas, 10 percent; and rivers and lakes, 5 percent. If the most important category is agricultural land, the dot grid intensity would be calculated on this basis. If the population being sampled is large, the number of samples may be computed by a formula based on the binomial distribution:

$$n = p(1-p)\left[\frac{t}{E}\right]^2$$

Where: n = total number of samples (dots) to be counted.
p = estimated proportion of the total area in the most important type classification (0.60 in this case).
t = a constant denoting the reliability of the estimate or level of statistical significance (the value 1.96 used here denotes a statistical probability of being correct 95 times in 100).
E = maximum permissible error, expressed as a percent of total area. (In this case, ±2 percent or 0.02.)

Substituting the above values, we get:

$$n = 0.60(1-0.60)\left[\frac{1.96}{0.02}\right]^2 = 2{,}305 \text{ dots}$$

Thus if we are correct in the assumption that the true percentage of agricultural land is 60, then 2,305 dots should be spaced over the total area to insure a 95-percent probability of obtaining an estimated proportion lying between 58 and 62 percent. At the specified photo scale of 1:15,840, the total print area represented by 10 square miles would be 160 square inches. Therefore, the number of dots needed per square inch would be 2,305 ÷160, or about 14. Here, it would be most expedient to select a square-spaced grid having 16 dots per square inch.

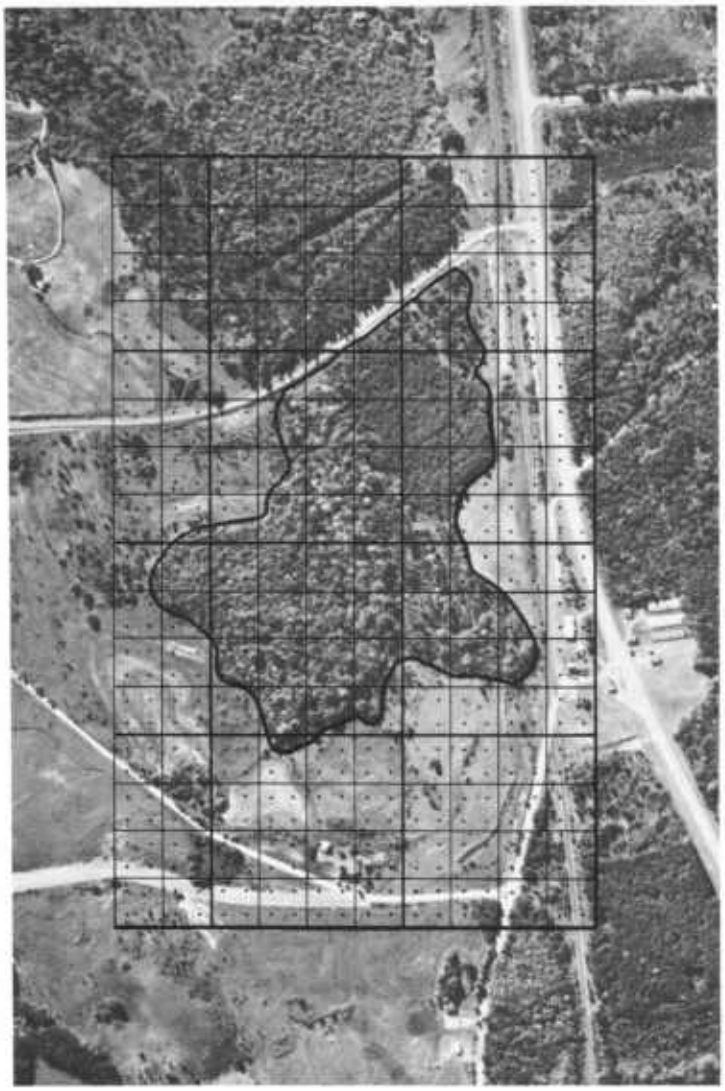

Figure 21.—**Dot grid positioned over part of an enlarged USDA print for acreage determination. The delineated stand contains about 25 acres. Photo scale is 660 feet per inch.**

The principal drawback to the formula method is that a prior knowledge of p is required, which is actually the value being sought. By definition, however, p always lies between 0 and 1, and it can be shown that $p(1-p)$ reaches a maximum value of 0.25 when p is set at 0.50 or 50 percent. Therefore, the equation may be revised to read:

$$n=0.25\left[\frac{t}{E}\right]^2$$

And, substituting values from the previous solution:

$n=0.25\left[\frac{1.96}{0.02}\right]^2=2{,}401$ dots, an increase of 96 dots over the first estimate.

A grid with 16 dots per square inch will still be adequate for the desired degree of accuracy ($16\times160=2{,}560$ dots).

For areas of 1,000 acres or less, grids with closely spaced dots are needed. Grids with 64 dots per square inch are commonly used with 1:20,000 photographs. As 1 square inch equals 63.77 acres at photo scale, each dot represents 0.996 acres. For 1:15,840 photography (40 acres per square inch), grids having 40 dots per square inch are available. It is not essential, of course, that a separate grid be used for each photo scale or that the number of dots per square inch be equal to the acreage per square inch. Wherever feasible, the preceding equation should be used to determine the grid intensity.

Tree Height

Tree heights are commonly determined on aerial photographs by measuring either stereoscopic parallax or shadow lengths. Though more difficult for the beginner, the parallax method is faster, requires fewer calculations, and is more adaptable to a variety of stand conditions. Anyone who can use a stereoscope can train himself to measure stereoscopic parallax, and even the occasional interpreter will find this method of measuring heights advantageous.

Shadow-length measurements are reliable only in open-grown stands where individual shadows fall on level ground. Accurate measurement is almost impossible in dense, irregular stands or on slopes. Furthermore, the conversion of shadow length to tree height is complex in comparison to the conversion of parallax measurements. For these reasons only the parallax method will be discussed. Foresters interested in details of shadow-height calculations should refer to Johnson's article (*8*), which includes a special form for making tree-height conversions.

The concept of parallax.—The Manual of Photogrammetry (*1*) defines parallax as "the apparent displacement of the position of a body with respect to a reference point or system, caused by a shift in the point of observation." In measuring object heights on stereoscopic pairs of aerial photographs, two types of parallax must be measured or approximated—the absolute and the differential. The absolute stereoscopic parallax of a point is "the algebraic difference, parallel to the air base, of the distances of the two images from their respective principal points" (*18*). The parallax difference, or differential parallax, of an object being measured for height determination is the difference in the absolute stereoscopic parallax at the top and the base of the object, measured parallel to the air base or flight line.

The formula for converting parallax measurements to tree height on aerial photographs is:

$$h=\frac{H\times dP}{P+dP}$$

where h = height of object
H = altitude of aircraft above ground datum
P = absolute stereoscopic parallax at base of object being measured
dP = differential parallax

If object heights are to be determined in feet, the height of the aircraft (H) must also be in feet. Absolute stereoscopic parallax (P) and differential parallax (dP) must be expressed in the same units; ordinarily, these units will be thousandths of inches or hundredths of millimeters.

The height of the aircraft above ground datum is calculated from the basic scale formula, transposed to the more convenient form: Flight altitude (H) = focal length × scale denominator. With photographs of 1:20,000 scale and a camera of 8.25-inch focal length, the flight altitude would be $0.6875\times20{,}000=13{,}750$ feet.

In flat terrain, the average photo base length is ordinarily substituted as the absolute stereoscopic parallax (P). If the ground elevation at the base of the tree being measured differs from the elevation of the principal points by more than 200 or 300 feet, however, the following method (*17*) should be used to calculate a new value for P:

1. Orient the stereo-pair with flight lines superimposed and images separated about 2.2 inches. Clip down photographs.
2. Measure the distance between the two principal points to the nearest 0.01 inch with an engineer's scale.
3. Measure the distance between corresponding images on the two photographs at or near the base of the tree to the nearest 0.01 inch.
4. Subtract (3) from (2) to obtain the absolute stereoscopic parallax at the base of the tree.

Differential parallax (dP) is usually measured stereoscopically with either a parallax wedge or parallax bar, employing the "floating mark" principle. Such instruments are discussed in the section that follows. The concept of differential parallax can be illustrated by direct measurement of severely displaced images such as in the large-scale stereogram of a water tank in figure 22. With a photo scale of 1:7,800 and a camera focal length of 6 inches, flight altitude above ground (H) is computed as $0.5\times7{,}800$ or 3,900 feet. Average photo base length (P) for the stereo-pair is 3.70 inches.

Absolute stereoscopic parallax at the base and top of the water tank is measured parallel to the line of flight with an engineer's scale; the difference (2.27−2.13 inches) is dP, the differential parallax of the displaced images. As the tank is somewhat tapered in form, measurements were made at the midpoint of the base and vertically above this position at the center of the top. Substituting in the parallax formula:

$$\text{Height of tank } (h)=\frac{3{,}900\times0.14}{3.70+0.14}=\frac{546.00}{3.84}=142 \text{ feet}$$

Parallax wedges.—Parallax wedges are usually printed on transparent film or glass. The basic design consists of two rows of dots or graduated lines beginning about 2.5 inches apart and converging to about 1.8 inches apart. The graduations on each line are calibrated for making parallax readings to the nearest 0.002 inch. The "training wedge" in figure 23 is graduated for reading to the nearest 0.01 inch only.

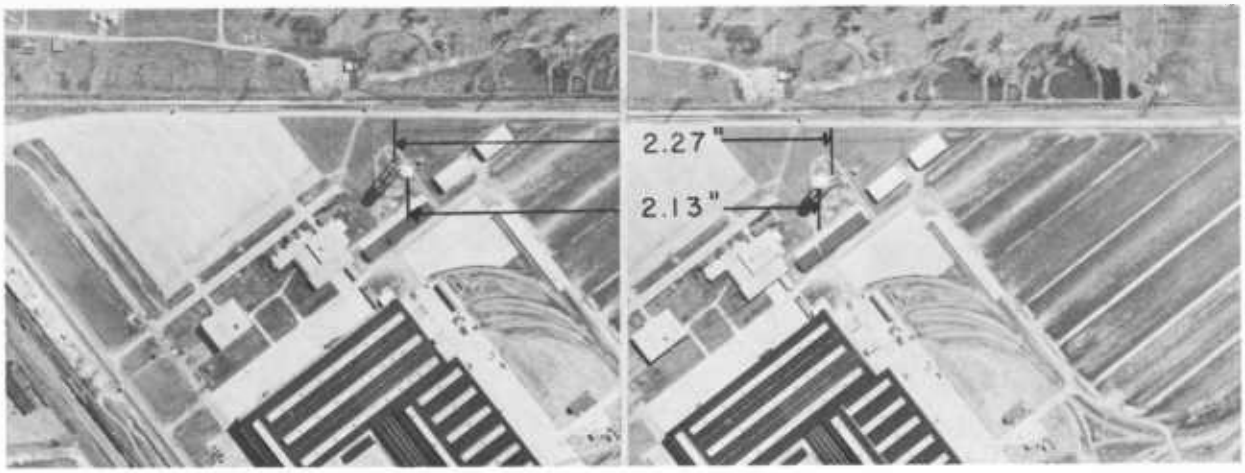

Figure 22.—Large-scale stereogram showing an industrial plant and heavily displaced water tank. Measurements of stereoscopic parallax shown can be used to determine height of the tank above ground. (Courtesy of Abrams Aerial Survey Corporation.)

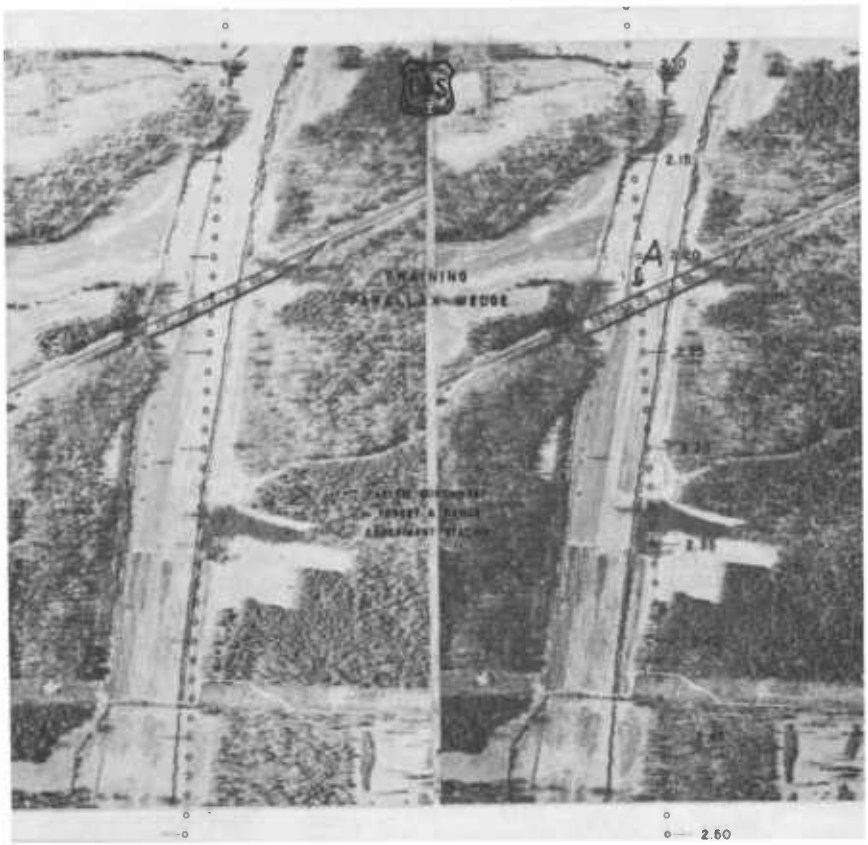

Figure 23.—Parallax wedge correctly oriented over a large-scale stereogram of a railroad trestle. Graduations on right-hand row of dots refer to separation of the converging lines in inches. (Courtesy of Abrams Aerial Survey Corporation.)

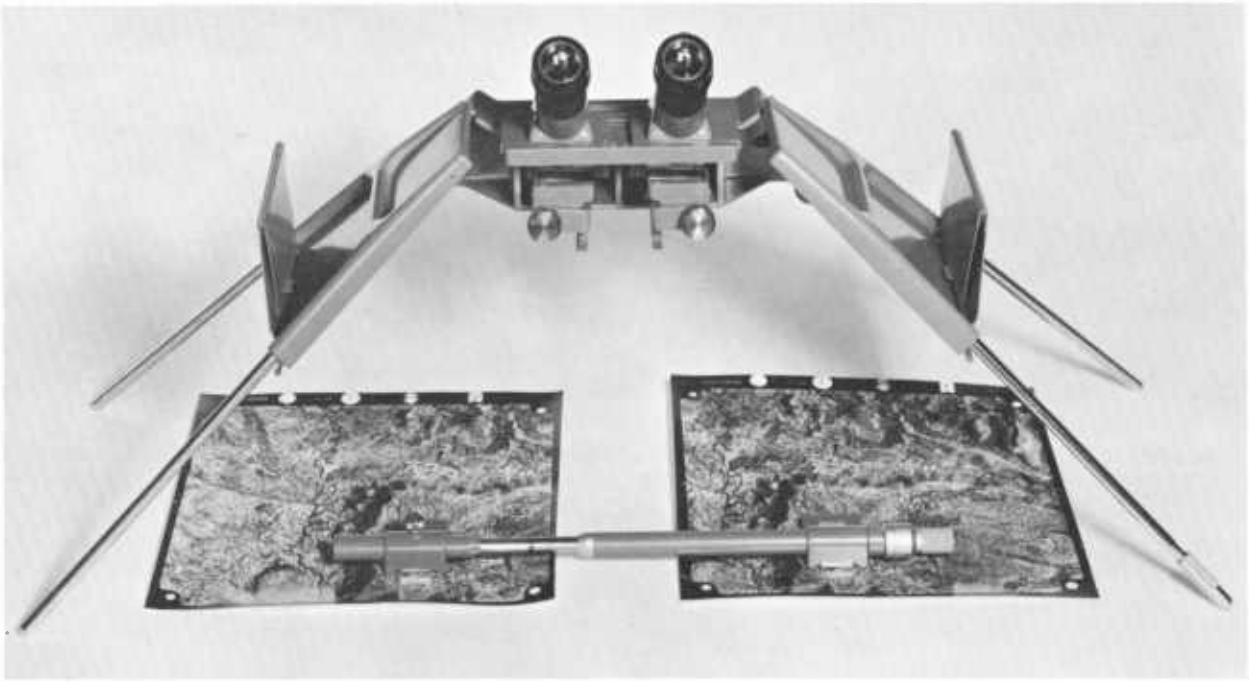

Figure 24.—**Modern mirror stereoscope with inclined magnifying binoculars. Positioned across the two photographs is a parallax bar (stereometer) for measuring heights of objects. (Courtesy of Wild-Heerbrugg Instruments, Inc.)**

The parallax wedge is placed over the stereoscopic image with the converging lines perpendicular to the line of flight and adjusted until a single fused line of dots or graduations is seen sloping downward through the stereoscopic image. If the photo images are separated by exactly 2 inches, a portion of the parallax wedge centering around the 2-inch separation of converging lines will fuse and appear as a single line. The line will appear to split above and below this section. Using the fused line of graduations, the differential parallax is obtained by counting the number of dots or intervals between the point where a graduation appears to rest on the ground and the point where a graduation appears to "float" in the air at the same height as the top of the object. In figure 23, for example, the dot resting on top of the railroad trestle yields a reading of 2.22 inches. When this value is subtracted from a ground reading of 2.26 inches, dP is determined as 0.04 inches. If flight altitude (H) of 4,000 feet and a photo base length of 3.56 inches, the parallax formula yields:

$$\text{Height of trestle } (h) = \frac{4{,}000 \times 0.04}{3.56 + 0.04} = \frac{160.00}{3.60} = 44 \text{ feet}$$

The interpreter should remember that the degree of stereoscopic parallax normally encountered on 1:12,000 to 1:20,000 USDA photographs is much less than that illustrated here. Nevertheless, the principle and the methods of measurement are exactly the same. Where P is large in relation to dP, tables 2 and 3 can be used as shortcut approximations in converting parallax measurements to object heights on USDA photographs.

The parallax bar.—This instrument is more expensive than the parallax wedge and yields results of comparable accuracy. But many interpreters prefer the parallax bar because the floating dot is movable and thus easier to place on the ground and at crown levels. A parallax bar designed to measure heights with a mirror stereoscope is shown in figure 24.

The bar has two lenses attached to a metal frame that houses a vernier and a graduated metric scale. The left lens contains the fixed reference dot; the dot on the right lens can be moved laterally by means of the vernier. The bar is placed over the stereoscopic image parallel to the line of flight. The right-hand dot is moved until it fuses with the reference dot and appears to rest on the ground at the base of the tree. The vernier reading is recorded to the nearest 0.01 millimeter. The vernier is then turned until the fused dot appears to "float" at treetop level, and a second reading recorded. The difference between the readings is the parallax difference (dP) in millimeters. This value can be substituted in the parallax formula without conversion if the absolute parallax (P) is also expressed in millimeters.

Accuracy of height measurements.—Accuracy in

TABLE 2.—*Parallax-wedge conversion factors for wedges reading to 0.002-inch parallax (dP)*[1]

Photo base (*P*) (inches)	Object height in feet per 0.002 inch of *dP*, at flight altitudes of —				
	6,000 feet	8,000 feet	10,000 feet	12,000 feet	14,000 feet

3.9	60	80	100	120	140
4.0	58	78	97	117	136

[1] To use table, measure parallax difference (*dP*) of object to nearest hundredth of a millimeter (as 0.57 mm., for example). If average photo base (*P*) is 3.1 inches and flight altitude is 12,000 feet, the table value of 151 is multiplied by 0.57 for an object height of 86 feet.

measuring total heights of trees and stands depends upon a number of factors, not the least of which is the interpreter's ability to determine stereoscopic parallax. Usually interpreters can detect differences in parallax of about 0.002 inch, or 0.05 mm., and this graduation interval is used on most parallax wedges.

The interpreter who can detect a difference of 0.002 inch of stereoscopic parallax will be able to stratify forest stands into 10-foot total height classes on contact prints of 1:15,840 to 1:20,000 scales (*18*). Greater accuracy may be possible in flat terrain where photo scale changes are not pronounced and less skill is required in selecting the point for the base parallax reading. The ground parallax must be read on the same contour as the base of the tree.

The interpreter should consider the following points to improve accuracy in height measurement:

1. In rough terrain, a new photo scale and flight altitude should be calculated for each overlap. For stands on high ridges or in deep ravines, it is better to calculate new values for absolute stereoscopic parallax than to use the average photo base length.
2. Once a pair of photographs have been alined for stereo-viewing, they should be fastened down. A slip of either photograph between the parallax reading at the base and the top of a tree may cause highly inaccurate height readings.
3. To avoid single measurements of high variability, several measurements should be made of the same tree or stand and the results averaged.

Tree Crown Diameter

For most conifers and many hardwoods, tree crown diameter is related to stem diameter. It is thus a useful photographic measurement when estimating individual tree volumes or stand-size classes. Actual determination of crown diameter is a distance measurement, somewhat complicated by the small sizes of tree images and the effects of crown shadows.

Crown diameters are measured with either wedges or dot-type scales reading in thousandths of an inch. With a crown wedge, the diverging lines are placed tangent to both sides of the crown for making the reading. Dot-type scales have circles of graduated sizes for direct comparison with tree crowns (fig. 25). For converting measurements, the scale of photography is calculated in feet per thousandth of an inch. At 1:20,000, each 0.001 inch of crown measure equals 1.667 feet. A reading of 0.010 inch would imply a crown diameter of 17 feet (table 4).

Tree crowns are rarely circular, but, because individual limbs are often invisible on aerial photographs, they usually appear roughly circular or elliptical. Since only the parts visible from above can be evaluated, photo measures of crown diameter are often lower than ground checks of the same trees. Nevertheless, most interpreters can determine average crown diameter with reasonable precision if they take several readings.

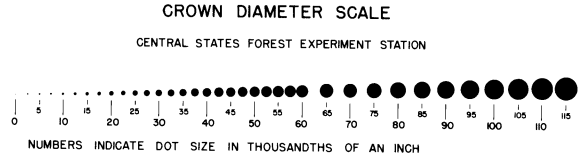

***Figure 25.*—Dot-type scale for measuring crown diameters. Such scales are usually printed on transparent film.**

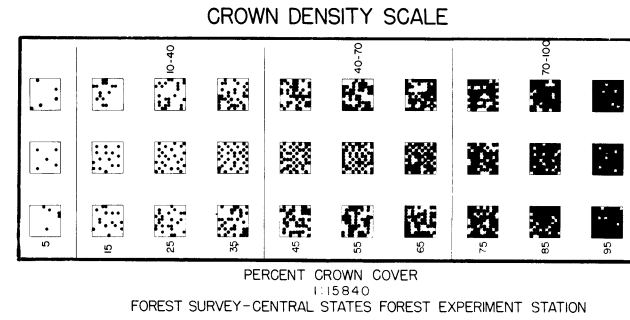

***Figure 26.*—Density scale for comparison with photo images in estimating crown closure percent.**

Obviously, crown diameter measurements of individual trees are most accurate in open-grown stands. In dense stands, measurements are generally confined to determination of an average for the dominant trees. Crowns of mature conifers can usually be classified into 5-foot classes without difficulty (*18*).

Tree Crown Closure

Crown closure percent, also referred to as crown density, is the proportion of the forest canopy occupied by trees. Crown density may refer to all crowns in the stand regardless of canopy level or only to the dominants. Estimates are purely ocular, and stands are commonly grouped into 10-percent density classes. Printed density scales (fig. 26) may aid the interpreter, though the patterns of black dots on a white background bear little resemblance to photographic images of trees. Comparative stereograms illustrating various stand densities have also proved useful (fig. 27).

Evaluation of crown closure is much more subjective than the determination of tree height or crown diameter. Actual measurement is virtually impossible on most USDA photographs, and accuracy is thus dependent on the interpreter's judgment. Inexperienced interpreters tend to overestimate closure by ignoring small stand openings or including portions of crown shadows. Devices for checking closure on the ground fail to provide estimates that are truly comparable to those made on vertical photographs. Thus the neophyte must rely on practice, checked by skilled interpreters, to develop proficiency.

Crown closure is useful because of its relation to stand volume per acre. It is applied in lieu of basal area or number of trees per acre, as these cannot be accurately determined on available photography. Measurements of crown diameter and estimates of closure should always be made under the stereoscope.

Tree counts.—Complete tallies of individual trees can seldom be made accurately on available USDA photographs. In dense stands, suppressed trees and many intermediates cannot be seen. Clumps of two or three trees often appear as single

crowns, and ragged individual crowns may look like two trees. Only in even-aged, open-grown forests can all trees in a stand be separated. Counting all trees on a plot is tedious, and this measure of density is seldom used. Where large-scale photographs are available (1:1,000 to 1:5,000), individual-tree counts may be much more reliable.

AERIAL CRUISING

Individual Tree Volumes

Ordinary tree volume tables can be easily converted to aerial volume tables when correlations can be established between tree crown diameters and stem diameters (*10*). The photographic determinations of crown diameter and total tree height are merely substituted for the usual field measures of stem diameter (d.b.h.) and merchantable height, respectively (fig. 28). Photographic measurements are usually limited to well-defined open-grown trees, and crown counts are required to obtain total volume for a given stand of timber.

The construction and application of aerial tree volume tables depends on a well-established relationship between photographic measures of crown diameter and ground determinations of tree d.b.h. Such relationships can often be established for individual species or species groups, notably even-aged conifers in the middle diameter classes (*18*). By contrast, stem-crown diameter correlations rarely have been used for estimating volumes of mixed hardwoods.

The aerial tree table (table 5) provides volumes in terms of gross cubic feet. In making an aerial cruise, photographic measurements may include all trees on 0.2- to 1-acre circular plots, or stands may be delineated according to height classes for determination of the average tree per unit area. In the latter instance, a tree count must be made to obtain the total stand volume.

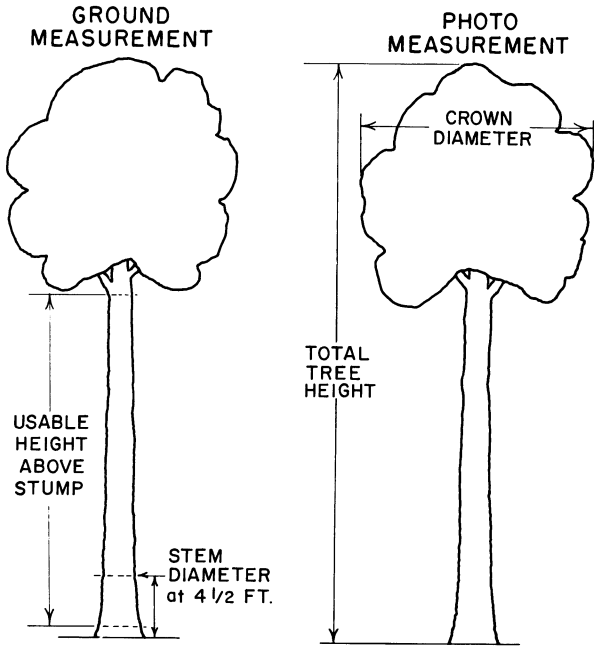

Figure 28.—**Comparison of ground and photographic measurements in the determination of individual tree volumes.**

In general, the individual-tree approach to aerial crusing is of limited value when the interpreter is restricted to use of 1:12,000 to 1:20,000 USDA photographs. At this scale, images are usually too small for accurate assessment of individual trees.

Stand Volume Per Acre

If recent photographs and reliable aerial stand-volume tables can be obtained, average stand volume per acre can be estimated with a minimum of field work. Estimates are made in terms of gross volume, as amount of cull or defect cannot be adequately evaluated. Even-aged stands of simple species structure are best suited for this type of estimating, especially if gross and net volumes are essentially identical. All-aged stands of mixed hardwoods are more difficult to assess, but satisfactory results can be obtained if field checks are made to adjust the photographic estimate of stand volume per acre and to determine allowance for defect. Though volumes from photographs cannot be expressed by species and diameter classes, total gross volumes for areas as small as 40 acres can be estimated within 10 to 15 percent of volumes derived from conventional ground cruises (*13*).

Most aerial stand-volume tables for mixed species are constructed in terms of cubic feet per acre. Tables for species in pure stands, such as Douglas-fir, may be expressed either in board feet or cubic feet per acre. Three photographic measurements of the dominant stand are generally required for entering an aerial stand volume table: average total height, crown diameter, and crown closure percent.

Aerial volume tables have been constructed for many of the important timber associations in the United States. Included here are tables for Douglas-fir (table 6), Rocky Mountain conifers (table 7), and Kentucky hardwoods (table 8). Composite tables, applicable in mixed stands, are presented for northeast Mississippi (table 9) and for northern Minnesota (table 10). Crown diameter was eliminated as a variable in tables 6 and 10.

[1] Based on 342 trees in Arkansas, Lousiana, and Mississippi. Gross volumes are inside bark and include the merchantable stem to a variable top averaging 6 inches i.b. Reprinted from (*4*).

One of the several procedures for making aerial volume estimates is as follows:

1. Outline tract boundaries on the photographs, utilizing the effective area of every other print in each flight line. This assures stereoscopic coverage of the area on a minimum number of photographs and avoids duplication of measurements.
2. Delineate all forest types. Except where type lines define stands of relatively uniform stocking and total height, they should be further broken down into homogeneous units so that measures of height, density, and crown diameter will apply to the entire unit. Generally it is unnecessary to recognize stands smaller than 5 to 10 acres.
3. Determine the acreage of each condition class with dot grids. This determination can often be made on contact prints.
4. By stereoscopic examination, measure the variables for entering the aerial stand volume table. From the table, obtain the average volume per acre for each condition class.
5. Multiply gross volumes per acre from the table by condition class areas to determine gross volume.
6. Add class volumes for the total gross volume on the tract.

A practical application is illustrated by the stereogram in figure 29 and the corresponding cordwood volume summary. In this particular inventory, hardwood components in each stand were ignored, and estimates were derived only for pine timber. The aerial cruise, fortified by fre-

[1] Gross volume, in trees 5.0 inches and larger, from stump to top limit of 4.0 inches diameter inside bark. Reprinted from (*15*).

[2] Average height of dominants and codominants as measured in the field.

[3] Average estimates of several experienced interpreters includes all trees in the major canopy (occasionally excludes small trees definitely below the general canopy).

[1] Gross volumes are inside bark and include all trees 5.0 inches d.b.h. and larger from stump to a variable top diameter not less than 4.0 inches i.b. Volumes may be converted to rough cords per acre by dividing by 80.

[2] Based on 50 1-acre plots in Carlton County, Minn. Heavy lines indicate limits of basic data. Reprinted from (*5*).

quent field checks, was within 10 percent of a ground inventory made by an independent agency.

Adjusting volumes by field checks.—When aerial volume tables are not sufficiently reliable for acceptance of pure photographic estimates and allowance must be made for defective trees, some of the plots interpreted should be mechanically selected for field measurement. For example, if 350 plots were interpreted and every 10th plot selected, 35 plots would be visited in the field. If the field volumes averaged 600 cubic feet per acre as opposed to 800 cubic feet per acre for the photo plots, the adjustment ratio would be $600 \div 800$ or 0.75. If the 35 field plots are representative of the total, the ratio can be applied to the average photo volume per acre to determine the adjusted volume. Ratios should be computed by forest types, because hardwoods are likely to require larger adjustments than conifers.

The accuracy of aerial cruises depends not only upon the volume tables but also on the availability of recent photographs and the interpreter's ability to measure correctly. This last item may be the greatest single source of error. Each photo variable should be measured twice for an average, or two interpreters should assess each plot.

Photo estimates of pine cordwood volumes for a tract in the Georgia Piedmont [1]

County: Oconee
Photo No.: BQ–3BB–85, 86
Owner: J. Reynolds
Photo date: 11–1–60
Pine area: 177 acres
Scale: 1,667 ft./inch

[1] Cubic volumes derived from table 9 and divided by 80 for conversion to cords.

[2] Stands are numbered as in figure 29.

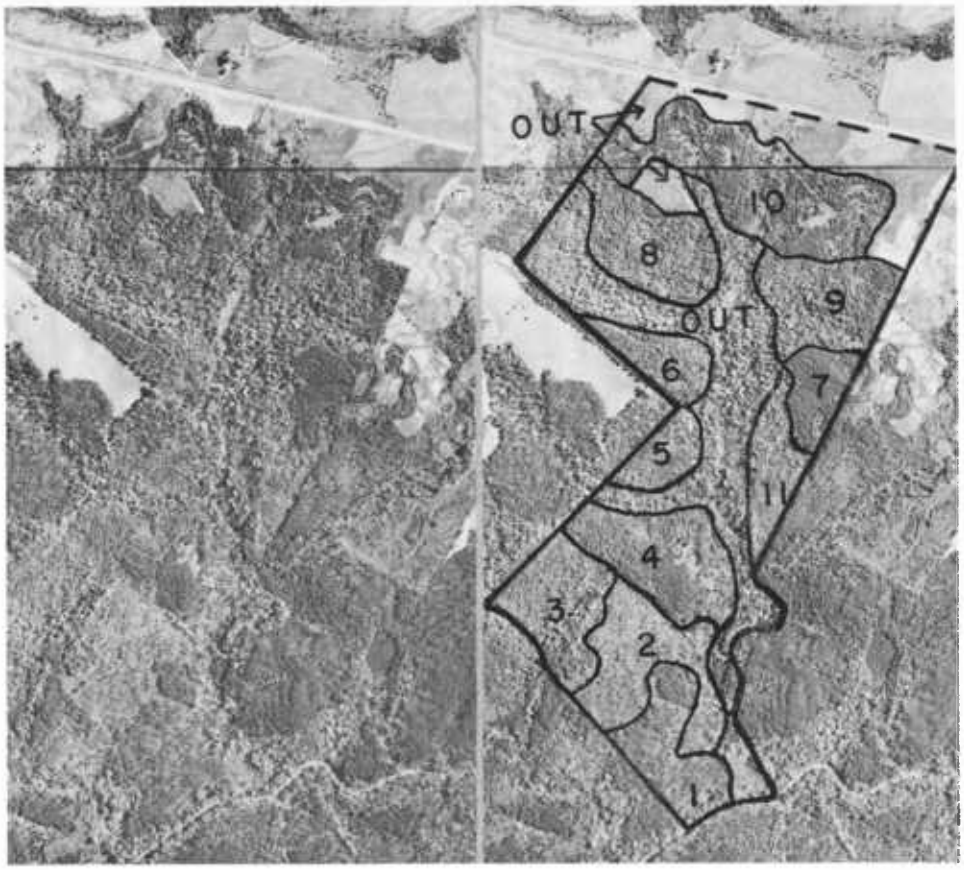

Figure 29.—**USDA panchromatic stereogram of a forest area in the Georgia Piedmont. Area and pine volume estimates were made for each of the stands numbered. Scale is about 1,667 feet per inch.**

PHOTO STRATIFICATION FOR GROUND CRUISING

A photo-controlled ground cruise combines the features of both aerial and ground estimating, offering a means of obtaining timber volumes with maximum efficiency. Photographs are used for area determination, for allocation of field samples by forest type and stand-size classes, and for designing the pattern of field work. Tree volumes, growth, cull percents, form class, and other data are obtained on the ground by conventional methods. A photo-controlled cruise may increase the efficiency, while reducing the total cost, of an inventory on tracts as small as 100 acres.

The approach to an inventory of this kind depends largely on the types of strata recognized and the method of allocating field samples. Cost and the statistical accuracy required determines the total number of field samples to be measured. Once this number has been determined, there are several ways in which the samples may be distributed among various photo classifications:

1. By area of each class. Though sometimes used, this method is often unsatisfactory because stands of low value may occupy the greatest acreage while high-value stands may be insufficiently sampled. The opposite extreme may result if value alone (volume-per-acre classes) is used.
2. By applying different cruising intensities to each class. A 20-percent cruise might be used for high-value stands, 10 percent for medium value, and 5 percent or less for low-value areas. This arbitrary method is better than using acreage alone, but it may not be the most economical and efficient.
3. By statistical methods. A preliminary cruise or a good estimate of the variability within each class must be made before the required number of plots per class can be computed. This approach is best for large tracts; for small ones it may be costly or unwieldy.

4. By a combination of area and value (volume). This is the preferred approach for small areas. A suggested procedure adopted from Johnson (*6*) and Spurr (*18*) follows.

Plot allocation by area and volume.—Assume that the tract is 1,600 acres and that 400 field plots are to be distributed among three forest types (pine, pine-hardwood, and hardwood) and three volume classes within each type (5, 8, and 12 cords per acre).

1. Stratify each forest type into volume-per-acre classes on the basis of personal experience or with aerial stand-volume tables. Precision is not required, as the volume classes are used only as a guide. Tabulate by type and acreage:

Cords per acre	*Pine (acres)*	*Pine-hardwood (acres)*	*Hardwood (acres)*
5	120	200	100
8	100	500	350
12	80	100	50
Total	300	800	500

2. Multiply the number of acres in each class by the cord volume per acre. The product is the number of cords per class:

Pine	*Pine-hardwood*	*Hardwood*
5×120= 600	5×200=1, 000	5×100= 500
8×100= 800	8×500=4, 000	8×350=2, 800
12× 80= 960	12×100=1, 200	12× 50= 600
2, 360	6, 200	3, 900

3. Add the cordage in each class to get the total for the entire area: 2,360+6,200+3,900=12,460 cords. Divide by the number of plots to get the number of cords to be represented by each plot:

$$\frac{12,460}{400}=31.15 \text{ cords per plot}$$

4. Divide the volume for each class (item 2) by the cord volume per plot to get the number of plots assigned to each class. Round to the nearest whole number. Add the plots for each class to make sure the total (400) is correct.

Pine	*Pine-hardwood*	*Hardwood*
$\frac{600}{31.15}=19.26(19)$	$\frac{1,000}{31.15}=32.10\ (32)$	$\frac{500}{31.15}=16.05(16)$
$\frac{800}{31.15}=25.68(26)$	$\frac{4,000}{31.15}=128.41(128)$	$\frac{2,800}{31.15}=89.88(90)$
$\frac{960}{31.15}=30.82(31)$	$\frac{1,200}{31.15}=38.52\ (39)$	$\frac{600}{31.15}=19.26(19)$
(76)	(199)	(125)

Total: 400 plots

Arrangement of ground samples.—If type boundaries have been accurately delineated and stands are homogeneous within the recognized classes, field plots can sometimes be taken along routes of easy travel without introducing much bias. Usually, though, it is necessary to lay out line-plot or strip cruises at right angles to topography. The cruise lines should be drawn to scale on a type map in such a way that the required number of samples within each class can be obtained. The number of plots or chains of strip that a crew can complete per day is the basis for calculating the lengths of the lines. To minimize travel, lines may be triangular or U-shaped, beginning and ending near the same starting point on a road or trail. Compass bearings and distances can be determined on the map to avoid location bias in the field. The cruise lines can then be placed on the photographs for use in the field, if desired.

Field measurements are taken by conventional procedures. Cumulative tally sheets or point-sampling may be employed to speed the tree tally. After the cordage per acre for each volume class has been determined by field sampling, the values are multiplied by the appropriate stand acreages. The result is the total volume on the tract, by forest types:

Assumed volume class (cords per acre)	*Field plots (number)*	*Field volumes per acre (cords)*	*Type area (acres)*	*Volume per class (cords)*
PINE TYPE				
5	19	3. 9	120	468. 0

AERIAL PHOTOGRAPHS IN GEOLOGIC INTERPRETATION AND MAPPING

By Richard G. Ray

ABSTRACT

Aerial photographs today are widely used to obtain both qualitative and quantitative geologic information; vertical aerial photographs are used almost to the exclusion of other types. Techniques and procedures described herein relate primarily to vertical photography.

Geologic interpretation of aerial photographs is based on the fundamental recognition elements of photographic tone, color, texture, pattern, relation of associated features, shape, and size. The scale of photographs, as well as the vertical exaggeration that is present in most stereoscopic models, also are significant in photointerpretation.

The amount of geologic information that may be obtained from aerial photographs is primarily dependent on the type of terrain (igneous, metamorphic, or sedimentary), climatic environment, and stage of the geomorphic cycle. Because features are more readily recognized where strong differences exist in the erosional resistance of adjacent rocks, sedimentary terrain may be expected to yield the greatest amount of information from aerial photographs. Metamorphic terrain may yield the least information because metamorphic processes tend to destroy differences that may have existed in the unmetamorphosed rocks. Combinations of criteria such as photographic tone, texture, pattern, and vertical exaggeration permit inferences as to rock type and geologic structure, which are important in petroleum exploration, ore-deposits search, and engineering geology.

In petroleum exploration aerial photographs provide a wealth of information primarily with regard to potential structural traps. Folds commonly may be interpreted from a study of strike and dip of bedding and from stream patterns; anomalous stream characteristics, such as stream deflections, may suggest subsurface structures. The variety of photorecognition criteria that suggests faults permits aerial photographs to be of particular use in many ore-deposits studies. Analysis of soil patterns yields information regarding permeability of the surficial materials that are a concern of the engineering geologist.

The instruments used for viewing photographs, measuring geologic features, and compiling geologic maps range from simple stereoscopes and stereometers, or measuring bars, to complex double-projection instruments such as the multiplex or Kelsh plotter. Some instruments require the use of paper prints; others require the use of glass-plate diapositives. Measuring devices primarily provide spot heights or differences in altitudes; these quantitative data may be geologically significant in measurement of stratigraphic thickness and dip of beds and in structure contouring. Accuracy of vertical measurements is related fundamentally to the scale of photography and the instruments used for making measurements. In general, accuracy of measurement is greater when large-scale photographs are used and when double-projection instruments rather than simple parallax bars are employed.

INTRODUCTION

Use of aerial photographs to obtain geologic information—popularly called photogeology—has contributed to mineral and fuel discoveries, and to engineering geology studies, as well as to the general geologic mapping of many areas; it also has increased the efficiency of many geologic mapping groups by adding speed, economy, and accuracy to areal mapping as well as adding certain geologic information that is impossible, difficult, or economically impractical to obtain by routine field-mapping methods. The past financial success of consultants in geologic interpretation of aerial photographs attests to successful geologic application of photogeologic procedures and techniques, particularly in petroleum geology, and to lesser extent in mining and engineering geology.

Many technical papers on the geologic interpretation of aerial photographs have been published, primarily since the end of World War II; on several occasions symposia on photointerpretation, and specifically photogeology, have been presented. Much of the information currently available has been published as individual articles and they are scattered throughout the literature; comprehensive treatments on the geologic interpretation of aerial photographs are generally unavailable now (1959) (see Eardley, A. J., 1942; Smith, H. T. U., 1943b; and Petrusevich, M. N., 1954). In addition to the published information much unpublished information also has accumulated in recent years. The collection and synthesis of much of this information, together with discussion of photointerpretive and related photogrammetric procedures, are the main objectives of this paper. The paper is particularly intended as a guide to geologic interpretation of aerial photographs as applied as a tool in reconnaissance geologic mapping, and as a reference to published papers representative of the photogeologic literature.

The primary objectives of photogeology are (a) to contribute to geologic mapping, which in turn is basic to mineral and fuel exploration, engineering geology studies, some water-resources investigations, and related studies, and (b) to contribute to geologic knowledge through research. The objectives of photogeology may be economic or academic, and procedures used can be expected to differ widely, ranging, for example, from use solely of simple lens stereoscopes for qualitative interpretation to employment of precision stereoplotters for making geologic measurements. Regardless of procedures used, however, photogeology to date has contributed principally to the broad aspects of geologic study, that is, in mapping distribution of rock types and structures. The interpreter can only infer the composition of rock types from photographs; he cannot identify mineral types or absolute ages of rocks. Thus, maximum use of photogeologic procedures is attained by combining photogeologic studies with various laboratory studies and with field investigations.

The uses of aerial photographs and the various photogeologic procedures are discussed herein under the general headings of interpretation and instrumentation. The part dealing with interpretation is widely illustrated with stereoscopic pairs and triplets, single photographs, and mosaics, together with explanatory notes, to demonstrate the kinds and amounts of geologic information that can be obtained from aerial photographs of differing geologic terrains and to illustrate some uses of photographs in specific studies, such as the search for petroleum. These photographs demonstrate primarily the qualitative uses of the fundamental recognition elements in geologic interpretation; they represent only a sampling of the tremendous number of illustrations available. Because reproduction processes tend to obscure details only subtly expressed on aerial photographs, selection of photographs used in this paper was confined principally to those that illustrate clearly defined recognition elements and geologic features. All aerial photographs (figs. 39–114) are at the end of the paper. Agencies holding the negatives of these photographs are given in a list that follows the photographs.

Methods and significance of determining quantitative geologic information from aerial photographs are described under the heading of instrumentation.

THE AERIAL PHOTOGRAPH

The aerial photograph is an instantaneous record of the ground details as determined chiefly by the focal length of the camera lens, the flying height of the airplane at the time of exposure, and the film and filters used. It may also be defined as a composite of photographic images, which make up the recognition elements used for interpretation. The aerial photograph is a perspective photograph that is geometrically related to the type of camera in which it is taken; it may be a vertical photograph, taken with the camera axis pointing essentially vertically down, or it may be an oblique photograph, taken with the camera axis purposely tilted from vertical, generally 20° or more. Vertical photographs currently are used almost to the exclusion of oblique photographs for geologic interpretation, and most photogrammetric instruments used in photogeology in the United States are designed to accommodate vertical photographs; hence the following discussion is limited to techniques applicable to the study of vertical photography. Twin low-oblique photographs—those in which the apparent horizon is not shown—generally may be transformed and the resulting paper prints used as vertical photographs; however, low-oblique photographs cannot be used in many stereoplotting instruments unless the instruments are specially designed.

A general knowledge of the geometry and terminology used with vertical aerial photographs is necessary if one is to understand and make maximum use of photographs for interpretation and mapping purposes. The terminology and geometry of the vertical photograph are presented in figure 1.

FACTORS THAT AFFECT THE PHOTOGRAPHIC IMAGE

Factors that affect the photographic image, and hence interpretation, may be divided into two groups: (a) The relatively constant man-controlled factors, such as focal length of lens, flying height, film and filter combinations, and lens angle; and (b) the variable natural factors including color of objects photographed, position of an object with respect to the angle of sun, amount of haze in the atmosphere, and others. The constant factors are discussed briefly below; effects of natural factors on the photographic image are described where appropriate throughout the text.

FOCAL LENGTH AND FLYING HEIGHT

Focal length and flying height may be considered together because of the relation of photograph scale to these two factors. In terms of focal length and flying height, the average scale of a photograph is expressed as

$$S=\frac{f}{H}$$

or

$$\text{Scale}=\frac{\text{focal length (feet)}}{\text{flying height (feet)}}.$$

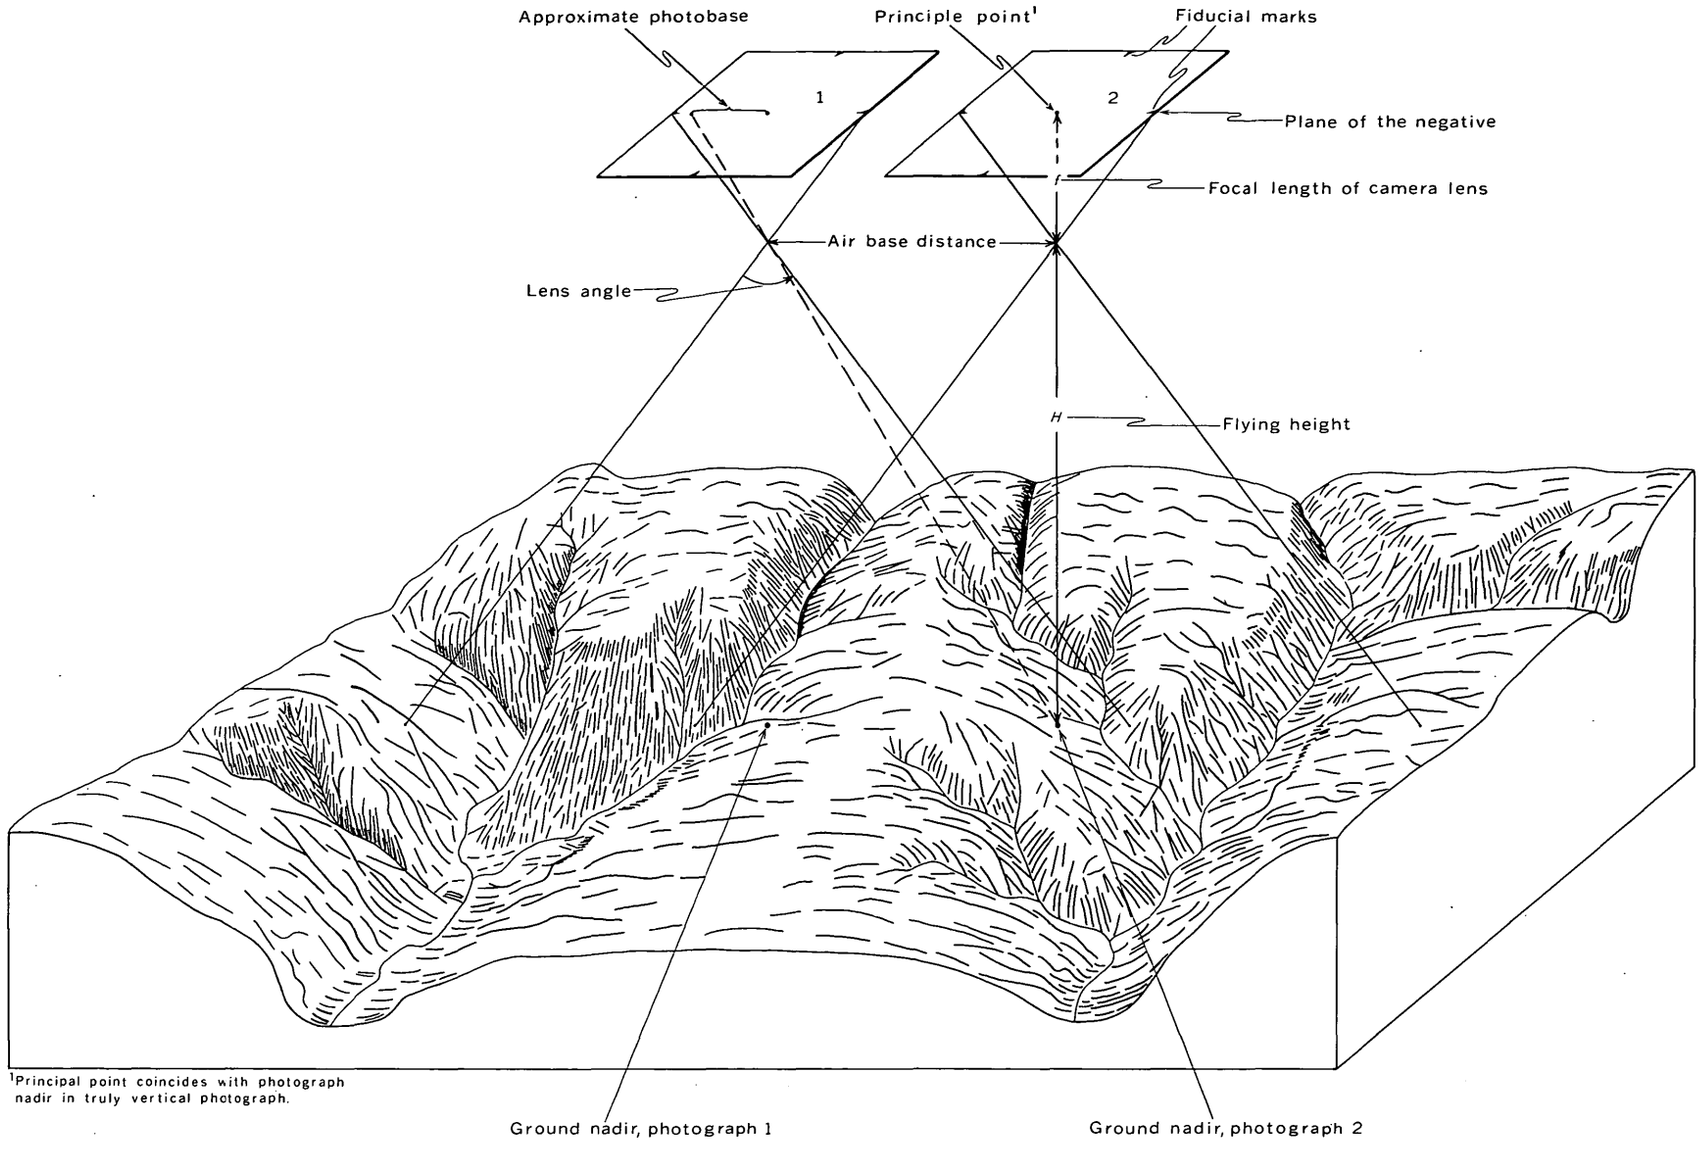

FIGURE 1.—Geometry of the vertical aerial photograph.

Thus, for example, the scale of photographs taken at 10,000 feet above mean terrain with a 6-inch (0.5 foot) focal-length lens is

$$\frac{0.5}{10{,}000}=1:20{,}000.$$

It is evident that as focal length increases, the scale of photographs becomes larger, but as flying height increases, scale of photographs becomes smaller. Therefore, at any given flying height, long-focal-length lenses result in larger scale photographs than short-focal-length lenses. It follows also that at a given flying height a greater number of photographs are necessary to cover a given ground area when long-focal-length lenses are used. Doubling the focal length of the lens, for example, will quadruple the number of photographs required to cover a given area at a given flying height.

It should be noted that if a photograph is enlarged or reduced, the "effective" focal length for that photograph is also changed in direct proportion to the amount of enlargement or reduction. Thus, if photographs taken with a 6-inch-focal-length lens are enlarged two times, the effective focal length is changed from 6 inches to 12 inches. Parallax measurements (see p. 53), used in determining differences in altitude, are increased, but the absolute value for each unit of parallax measurement is decreased. Reducing or enlarging photographs thus has a significant effect with respect to choosing appropriate measuring and plotting instruments, and in measuring differences in altitudes.

For determining scale from the formula $S = f/H$ the effective focal length must be used where photographs have been reduced or enlarged. Particular note should be made in the use of transformed low-oblique photographs, in which the effective focal length is almost always less than the focal length of the camera.

FILM AND FILTER COMBINATIONS

The appearance of the photographic image may be controlled to marked extent by the sensitivity of the film and by the light transmission of the filter employed. The sensitivity of a film emulsion may be controlled when the film is manufactured so that all or only selected parts of the visible spectrum are recorded, or so that part of the invisible spectrum, such as infrared light, is recorded. Also, the wave length of light reflected from an object and actually recorded may be controlled in part by filter combinations. The recording of selected wave lengths of light, controlled by filters or type of film, or by combinations of film and filters, affects the photographic image, primarily by affecting the photographic tone. Conventional panchromatic aerial film is generally exposed through a minus-blue filter and permits the recording of blue-green, yellow, orange, and red light. When color film is used the entire visible spectrum is commonly recorded and a greater number of color differences can be distinguished than on conventional black-and-white film. Special color film or color film used with filters may distort the color of the objects photographed, but if differentiation of geologic features is permitted, then lack of color fidelity may not be detrimental to interpretation. Ideally, film and filter combinations may be used to accentuate specific features for a given type of interpretation (see p. 7–8).

LENS ANGLE

The angle of the camera lens—that is, the apex angle of the cone of rays passing through the lens—is important indirectly in relation to radial displacement and parallax measurements, which are in turn significant with regard to photogrammetric applications in geologic interpretation. Characteristically, long-focal-length lenses (greater than 6 inches) have a narrower lens angle than short-focal-length lenses (6 inches or less). Thus, to maintain a given scale and format size, photographs taken with a narrow-angle (long-focal-length) lens requires flying at a higher altitude than with a wide-angle (short-focal-length) lens. Under these conditions, radial displacement (also termed "relief displacement") of similar image points is less when narrow-angle lenses are used, but only because of the greater flying height required by the narrow-angle lens to maintain the given scale and format size. The parallax difference for an object of specific height is in turn affected as a result of the difference in flying height, the parallax difference decreasing directly with increased flying height for a given focal-length lens (see p. 53). Thus it can be said that lens angle indirectly affects parallax measurement. When a constant flying height is maintained, however, lens angle does not affect parallax measurements of similar image points. Image distortion at the margins of photographs taken with a wide-angle lens may be greater than on photographs taken with a narrow-angle lens and this is considered by many to be detrimental to photointerpretation, especially in high-relief terrain.

VIEWING OF PHOTOGRAPHS

Photographs may be viewed singly, as mosaics, or as stereoscopic pairs. Most commonly stereoscopic pairs of paper prints are viewed in reflected light with simple lens, prism, or mirror stereoscopes, notes are made directly on the prints or on transparent overlays, and information is later transferred to a base map or

mosaic. Many paper prints can also be viewed with transmitted light, which may be helpful in revealing photographic detail. If vertical measurements are made from paper prints a separate measuring device must be commonly employed with the stereoscope. In recent years double-projection instruments, employing the anaglyph principle in forming the stereoscopic model from glass-plate diapositives, have been used increasingly in geologic interpretation.

When photographs are viewed singly or in a mosaic, a two-dimensional view is obtained. The single photograph or mosaic is normally viewed along a line generally perpendicular to the photograph surface, but for some subtle linear features, an oblique view of the surface with a reflected light source moved to different positions may reveal photographic details otherwise difficult or impossible to see (see Lattman, 1958, p. 575). Many valuable relations of geologic and associated features can be observed, particularly as a result of the overall view permitted by mosaics or single prints of small scale, but a two-dimensional view reveals only part of the data available to the interpreter; the value of three-dimensional, or stereoscopic, examination of aerial photographs in contrast to studying the two-dimensional view cannot be overemphasized. Conspicuous geologic features are commonly visible on single aerial photographs or mosaics of aerial photographs, but the wealth of information seen in stereoscopic view is many times greater. Details, such as fine lines or textural differences not readily seen on single photographs—or even on the ground—commonly are shown clearly in the stereoscopic model. Such clarity is in many places a direct result of the common association of fine lines and textures with relief changes, which are exaggerated in most stereoscopic models. To take advantage of the exaggerated vertical dimension, which is so helpful in photointerpretation, aerial photographs should of course be viewed stereoscopically. It may be desirable also to view the photographs pseudoscopically by reversing the print positions so that hills appear as valleys and vice versa. In pseudoscopic view, stream patterns or anomalies may stand out (see fig. 95), or because of the unnatural view other features may be accentuated. Aschenbrenner (1954, p. 401) demonstrated by the use of a seemingly random distribution of dots, which may be likened to silver grains of a photographic emulsion, that information not visible on a single picture can be clearly seen in stereoscopic view.

INTERPRETATION

Interpretation was defined broadly by Summerson (1954, p. 397) as the prediction of what cannot actually be seen; and thus geologic interpretation of aerial photographs is not unlike certain geologic interpretations of field-observed data. Colwell (1952, p. 535; 1954, p. 433) defined interpretation as "* * * the act of examining photographic images of objects for the purpose of identifying the objects and deducing their significance." However, geologic interpretation, more often than not, is a result of combined deductive and inductive reasoning, based on the principle of cause and effect. For example, certain features easily identified on aerial photographs, such as terminal moraines and kettle holes, are inductively concluded to have resulted from glaciation, and this in turn may lead by deductive reasoning to the specific identification of less readily recognizable features, such as certain kame terraces. Further deduction may lead to conclusions concerning the type of material present in these terraces. On the other hand, interpretation may be directed mainly toward understanding the geologic significance or history of a broad area, and specific features such as positions of beds and measurements of stratigraphic thicknesses combine by inductive reasoning to reveal the probable geologic conditions that resulted in those features.

Geologic interpretation of aerial photographs can be considered generally a two-step process. The first step includes observation, fact-gathering, measurement, and identification of features on the photographs. The second step involves deductive or inductive mental processing of these data in terms of geologic significance. According to Stone (1951, p. 755) a procedural or methodical approach to interpretation should be used because "The establishment of procedure prepares the way for orderly and complete analyses of complex subjects." A procedural or methodical approach appears to be especially applicable to the observational phase of a photogeologic study, and it will give a firm basis on which the interpretive phase is dependent.

Observational data, also termed "first-order" information (see Hopkins, Karlstrom, and others, 1955, p. 142), may be subjected to either the empirical or rational method of processing (Smith, H. T. U., 1953, p. 9–10). According to Smith (1953, p. 9) the empirical process is largely mechanical rather than perceptive, and involves matching images of a photograph with similar reference images; reasoning is largely by analogy and this "Reasoning by analogy alone is notoriously deceptive, unless extreme care is taken to make certain that the analogy is truly complete." Smith (1953, p. 9) also made the particularly significant statement that "Nature is not always so obliging as to provide the desired simplicity and uniformity of conditions" that would permit the ready application of empirical methods. Indeed, much in nature is com-

plex and nonuniform, many terrain features are polygenetic, and thus interpreting the geologic significance of observational data is dependent largely upon a thorough understanding of the principles of the sciences that explain the observational data. "The physical conditions of a particular terrain change, and the adjustment to that change is a gradual one, allowing all manner of intermediate forms and combinations between the norm for the old situation and that for the new" (Summerson, 1954, p. 396).

Surface expressions of geologic features—the observational data—range from the very obvious to the very subtle. Sorting those data that are significant to a particular problem and properly relating these features one to another provide a measure of the ability of the individual interpreter. Where more than one plausible explanation of observational data is possible, the experience as well as the fundamental geologic ability of the interpreter become especially significant. Thus a rational processing of observational data will yield the most meaningful interpretive results. This does not imply that an empirical method of processing observational data, exemplified by the numerous photointerpretation "keys," may not yield satisfactory results in certain geologic problems and terrains, but the logical, scientific approach demands a rational processing of observational data, particularly where inferences based on subjective interpretations are required.

If observational data cannot be rationally interpreted, they may still be of some empirical value. For example, an interpreter may recognize two zones of vegetation on aerial photographs. Without knowledge of plant ecology, he may infer that a geologic contact exists between the two vegetation types. But a knowledge of plant ecology, permitting a rational interpretation, might well have allowed a further inference that one type of rock or soil was likely to be highly permeable in contrast with the other, thus revealing information with regard to certain physical characteristics of the rock or soil, which in turn may suggest something of the lithologic character. Thus "* * * the understanding of any particular terrain requires more than the knowledge of the geology * * *" (Summerson, 1954, p. 397). The greatest understanding will be by individuals grounded in the natural sciences and who understand, as a result, the various factors that contribute to a particular region. Because any geologic terrain is normally a complex that also includes features of fundamental interest to the botanist, forester, soil scientist, and others, photogeologic interpretation must take cognizance of these related sciences. The combined use of vegetation, soils, and geologic features to interpret geology is an example of what has been termed the "convergence of evidence" principle (Colwell, 1952, p. 566).

Interpretation, then, begins with the observation, identification, and measurement of features on photographs. One of the most obvious features is that of landform, and it has been stated by Johnstone (1953, p. 265) that analysis of landforms constitutes the basis of photogeology. Smit Sibinga (1948) also pointed out the importance of landform, or geomorphic expression, in interpreting the lithologic character of rocks; but analysis of landform, however important, cannot be the complete basis for photogeologic interpretation, for there is additional "first-order" information such as vegetation patterns, soil patterns, and stream patterns; photogrammetric measurements also provide first-order data. Features other than landform may actually be more important for certain structural interpretations. For example, vegetation may grow along and mark the location of a fault. Thus, interpretation is based not only on landform but also on photographic tone differences, color differences, drainage patterns, erosion patterns, soil patterns, vegetation patterns, and any other surface expression of underlying geology. It is fundamental that photointerpretation is only applicable to those geologic features that do develop such surface expressions.

The many features of surface expression used in photogeologic interpretation are identified on the basis of recognition elements—characteristics of the photographs that result from the scale selected; the color of the rocks, vegetation, and soils of the terrain photographed; the kind of film and filters used; the processing of the film; and related factors. The most significant recognition elements are relative photographic tone, color, texture, pattern, and association of features. Shape is important in identifying many constructional landforms. Finite size as a recognition element for geologic interpretation has been used very little, although relative size is commonly considered by the interpreter. The increasing use of photogrammetry in geologic interpretation, however, portends an increasing importance for size, not so much as a recognition element in the usual sense of the word, but as an interpretation element (see p. 13). Shadows may help in distinguishing certain tree types, which in turn may have geologic significance.

INTERPRETATION FACTORS

RECOGNITION ELEMENTS

PHOTOGRAPHIC TONE

Photographic tone is a measure of the relative amount of light reflected by an object and actually

recorded on a black-and-white photograph; it is fundamental to all other recognition elements, except color. Tones on conventional photographs are usually shades of gray, but may be black or white. Because of the ability of the human eye to differentiate subtle tone changes, relative photographic tone is a significant asset in geologic interpretation of aerial photographs. However, photographic tone is subject to wide variation and there are limits to its usefulness as a recognition element because of the many factors that can influence it.

Photographic tone depends on light reflectivity, which in turn depends on location of an object with respect to the sun; thus the time of day and month of year are influencing factors. Haze strongly scatters light, particularly at the short or blue end of the spectrum and hence affects photographic tone unless corrective filters are used. Geographic latitude, angle of reflected light, sensitivity of film, light transmission of filters, and processing also may exert considerable effect on photographic tone. Hence a standardized tone scale (Daehn, 1949, p. 287) would appear to have little usefulness unless relative photographic tones on different photographs could be equated in terms of the tone scale. It is probable that the use of a densitometer to measure relative photographic tone in terms of the density of the negative would be a satisfactory measure of tone, even though many factors influence the density. Particularly in quantitative studies the use of a densitometer to measure relative photographic tone may prove very worthwhile in differentiating certain geologic features (Ray and Fischer, 1960).

Photographic tone, despite the many factors that may affect it, can be a particularly useful interpretation element; its usefulness depends on the problem under consideration and on how tone is used in conjunction with other recognition elements. For example, if the fracture pattern of an area were studied and it were known that a lush and dark-toned vegetation grew along the fractures because of concentration of moisture, the relative photographic tone probably would be a significant recognition element regardless of the limiting factors mentioned above. On the other hand, as a means of distinguishing between two types of trees that reflect similar amounts of light but which might signify differences in the underlying geology, photographic tone might be of little value unless used in conjunction with other recognition elements, such as crown texture.

Raup and Denny (1950, p. 120), in work along the Alaska Highway, considered photographic tone the least satisfactory criterion in identifying and interpreting vegetation. But Tator (1951, p. 717) considered tonal contrasts to be major keys for recognizing landscape features of low relief in the coastal region of the Gulf States, such tonal differences resulting mainly from soil and vegetation differences. Schulte (1951, p. 697) pointed out, with regard to pure stands of trees, that at large scales photographic detail is more important, but at small scales tone becomes relatively more important.

Because the analysis of photographic tone is highly subjective it has been suggested that photographic tone might not be as useful as other recognition elements in interpretation. Because of differences that may arise from position, angle of reflected light, processing, and other factors, Stone (1956, p. 125) stated that photographic tone in interpretation probably has been overemphasized. This is true if the factors that affect tone prevent photographic distinction of images that might otherwise be made. But if changes in relative photographic tone are present on a photograph, the interpreter should expect that these changes might be geologically significant. Indeed, photographic tone is probably the most used recognition and interpretation element, although it is generally used in conjunction with one or more other recognition elements. The absence of photographic-tone changes, as a result of processing and other factors, where such tone changes might normally be expected, does not detract from the possible usefulness of tone changes on other parts of a photograph. It merely suggests that the potential of photographic tone differences has not been accomplished for the photographs in question.

It is worthy of note that in interpretation strong tonal contrasts are generally desirable. Yet modern automatic dodging devices commonly used in printing photographs generally reduce overall tonal contrasts, although locally, as in darkly shaded areas or brightly lighted areas, automatic dodging may strengthen tonal contrasts. Because most aerial negatives are slightly lighter in the corners than in the center, hand dodging is commonly necessary if automatic dodging is not employed in making prints. However, undodged or hand-dodged prints are probably the best for general photointerpretation.

For special interpretation problems it may be possible to enhance tonal contrasts within a limited range of the tone scale by film intensifiers or other photographic processes, such as use of selected filters. Ray and Fischer (1960) used selected filters in photographing weathered samples of the Bernal and San Andres formations of New Mexico. The Bernal formation is a red thin-bedded shale and shaly siltstone; the San Andres limestone is primarily a grayish limestone. Spectral reflectance curves, based on spectrophotome-

ter studies, show significant differences for these two formations (fig. 2). Particularly at the short or blue end of the spectrum a strong difference in intensity of reflected light is present; the San Andres limestone reflects almost twice as much light as the Bernal formation. A noticeable difference is also present at the long or red end of the spectrum. But the spectral reflectance curves of the Bernal and San Andres formations within 500 to 675 millimicrons—the wave lengths generally recorded on conventional black-and-white aerial photographs—show that the overall light reflectance from these two formations would average out to be generally similar and little photographic distinction should be expected within this range. It is significant that strong reflectance differences which exist in one part of the spectrum may be masked by reflectance characteristics in another part of the spectrum, and therefore to achieve photographic distinction of two features, it would probably be necessary to record a restricted part of the spectrum. Photographs of the Bernal and San Andres formations taken through filters that permit recording only of reflected light at the short or long end of the spectrum show a marked photographic distinction of the two formations.

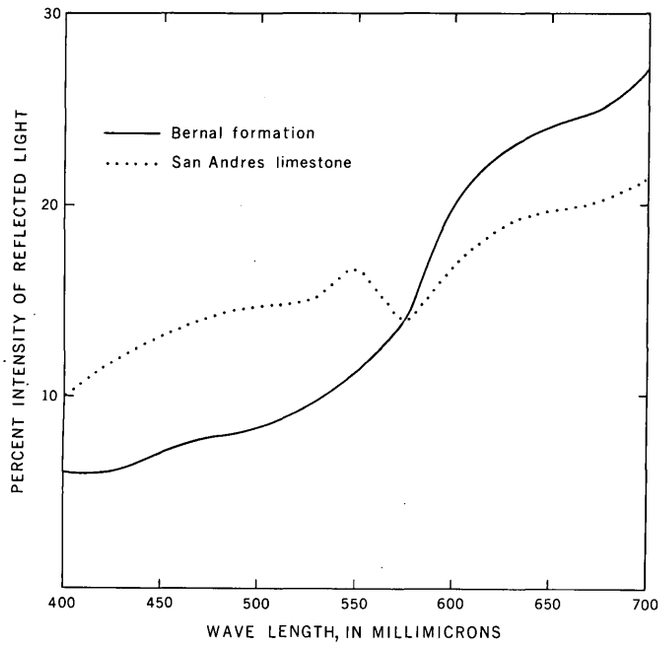

FIGURE 2.—Spectral reflectance curves of weathered samples of Bernal formation (red thin-bedded shale and shaly siltstone) and San Andres limestone (primarily a grayish limestone), New Mexico.

COLOR

Color as a recognition element could be one of the most useful, if not the most useful, criterion for interpretive purposes (see Kent, 1957; Ray, 1958; Fischer, 1958; and Minard, 1960). The significance of differences within a photograph is interpretation and the greater the number of differences, such as color contrasts, the greater is the potential for detailed interpretations. It is a well-established fact that the human eye can differentiate about 1,000 times as many tints and shades of color as it can tints and shades of gray, characteristic of black-and-white photographs, and hence it may be concluded that color aerial photographs will permit a greater amount of detail to be recognized and interpreted. However, it is possible that two rock types of similar color might be differentiated more easily on certain black-and-white photographs than on color photographs because of mineralogic, chemical, or other differences that may permit significant contrasts in reflected light to be recorded when selected films and filters are used.

Petrusevich and Kazik (1955, p. 5, 8) reported that where color contrasts of rocks are not strong, boundaries between these rocks are more clearly seen on black-and-white photographs than on color photographs. Where color contrasts are strong, interpretation is facilitated in areas where individual beds are rather thick and the color of formations is retained for considerable distances along the strike. Petrusevich and Kazik (1955, p. 8) also reported that "A comparison of aerial color photographs of scales 1:15,000; 1:10,000; 1:8,000; and 1:5,000 for the same area, taken under the same conditions, shows that * * * the practical use of aerial color photography for geological purposes should be limited to a scale of 1:10,000 and larger." This conclusion was based on a study of photographs taken with an 8.25-inch lens. Recently developed short-focal-length lenses (3.5 inches and 6 inches) now permit useful color aerial photography to be achieved at a scale smaller than 1:10,000.

Aerial color negative film may prove particularly useful in photointerpretive studies. Unlike positive transparencies (reversible-type color film), which require use of filters during exposure of the film, negative-type color film is processed with filters inserted during the printing process. It is thus possible to vary the color contrasts through the simple medium of printing, with the possible advantages that certain features of geologic significance, such as alteration zones, may be emphasized. Petrusevich and Kazik (1955, p. 5) noted that a greater contrast often can be obtained in a black-and-white print from a color negative than in a print from the corresponding black-and-white negative. Fischer (1958, p. 546) in turn stated that black-and-white positive prints from Ektachrome aero positive transparencies also show stronger tone

contrasts between various rock units than the conventional black-and-white photographs.

TEXTURE

Texture was defined by Colwell (1952, p. 538) as "* * * the frequency of tone change within the image * * * [and] * * * is produced by an aggregate of unit features too small to be clearly discerned individually on the photograph." The scale of the photographs thus has an important bearing on this definition of texture. For example, a network of fine lines described as a texture on one scale of photographs may well be recognizable as a network of joints on a larger scale of photographs; this bears out Schulte's statement (1951, p. 697), made with regard to plant distribution, that at large scales photographic detail is more important, whereas at small scales tone becomes relatively more important. Such a texture, due to tone change within the image, may be called a "photographic texture" (figs. 43, 56, and 85). Photographic texture is therefore a comparative feature within any one general scale of photography. Although photographic tone is a fundamental element of photographic texture, the photographic conditions that affect tone may vary and yet permit such a texture to be a diagnostic recognition element. This is due to the fact that texture in the photographic sense is really a composite of several fundamental characteristics, namely photographic tone, shape, size, and pattern, and, of these elements, slight variations of tone would least significantly affect the recognition of a given texture.

Photographic textures have been described by various workers (Spurr, 1948; Raup and Denny, 1950) as coarse, fine, rough, and fluffy, but such descriptive terminology would seem to have very limited use unless accompanied by photographic illustrations. Furthermore, unless these descriptive terms are themselves clearly defined, comparisons of photographic textures with specific commonly known objects might be more useful. It may also be suggested that because photographic textures are normally considered as two dimensional, the use of a densitometer in conjunction with a coordinatograph-type instrument to determine tone changes per millimeter within the image might permit mathematical classification of such textures. However, such a classification might fail where a strong textural fabric prevailed, for two textures differing primarily because of shape or preferred orientations within the image might well be assigned to the same mathematical classification.

In addition to the use of the term "texture" as described above, texture has other meanings, as in reference to soils. The application of aerial photographs to soils and engineering geology studies has resulted in the introduction of "soil texture" in some photogeologic literature; the obvious distinction between photographic texture, which can be directly observed, and soil texture, which must be interpreted from other recognition elements, must of course be made. Texture also has been used in relation to the density of a drainage network; wide spacing of streams results in a "coarse" texture of drainage and close spacing of streams results in a "fine" texture of drainage (figs. 3, 42, 49, 51, 62, 63, 79, and 106). Unless quantitative meaning is given to drainage texture, the term must be used on a comparative basis within any one general scale of photography. Horton (1945, p. 283–284) defined drainage density in quantitative terms but little use has been made of this classification by geologists.

Topographic texture has been used to describe the degree of dissection of the land surface (see Smith, K. G., 1950, p. 655–668). Like texture of drainage, topographic texture may be described as fine or coarse (figs. 39, 51, 62, 75, and 106). Quantitative study of topographic texture, based on map study, has shown that the texture ratio, a mathematical expression of the dissection of the ground surface, bears a logarithmic function relation to drainage density (Smith, K. G., 1950, p. 667–668). Therefore, because drainage density can be determined readily, aerial photographs may be useful in a comparative study of erosional topographies.

When texture is used to designate drainage density or erosional characteristics of the terrain, rather than to designate a photographic texture, the use should be so qualified as to make the definition clear. Although textures are commonly considered in terms of the two-dimensional plan view, it is important to note that erosional texture may well be significant or at least more readily recognized when viewed from the third dimension of the stereoscopic model (see fig. 39).

PATTERN

Pattern, as used herein, refers to the orderly spatial arrangement of geologic, topographic, or vegetation features. The spatial arrangement of pattern is normally considered by interpreters to be a two-dimensional or plan-view arrangement of features, but it may also be a three-dimensional arrangement. If features that make up a pattern become too small to identify, as on small-scale photographs, they may then form a photographic texture.

Patterns resulting from particular distributions of gently curved or straight lines are common and are frequently of structural significance; they may represent faults, joints, dikes, or bedding. But a single line, or lineation, is also an illustration of pattern; it

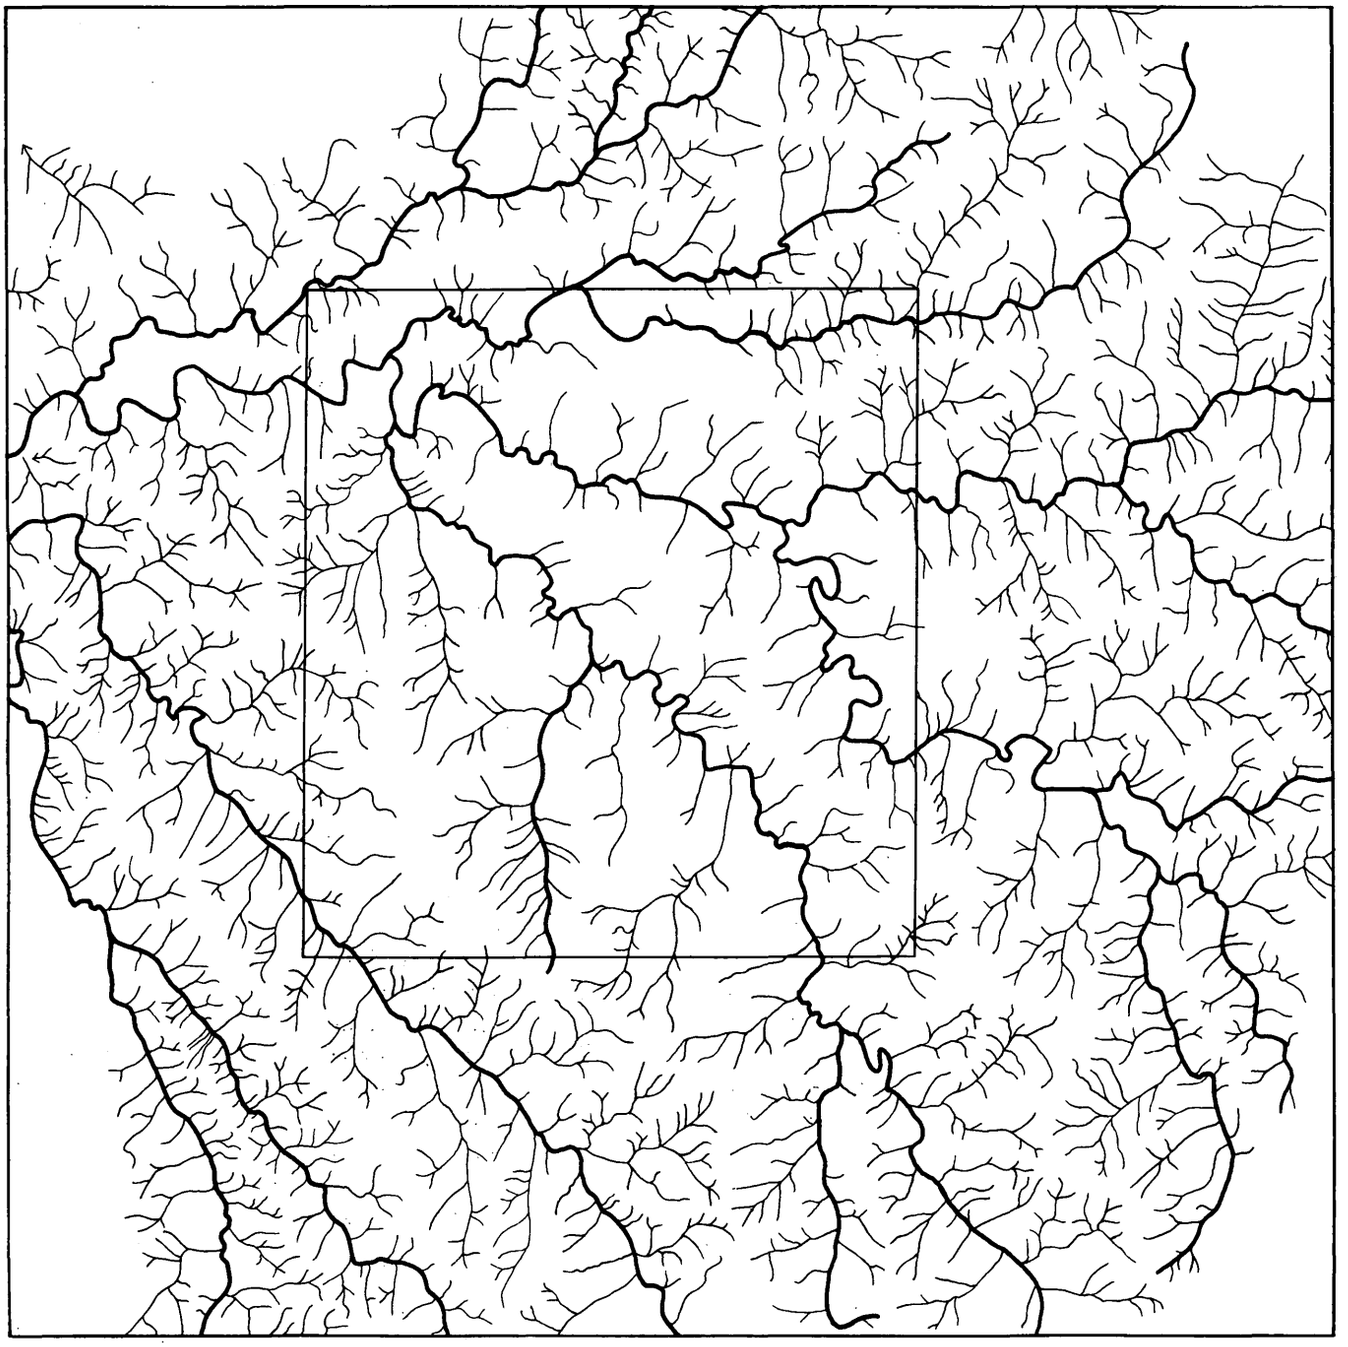

FIGURE 3.—Drainage map of large area in vicinity of ring dike shown in figure 54.

A separate tracing of drainage over a large area in the vicinity of the ring dike of figure 54 shows a marked decrease in drainage density within the ring-dike area. The contrast in drainage densities inside and outside of the ring dike is more readily seen on a separate tracing of drainage than in the stereoscopic model. (See also fig. 9.) Inset shows area of figure 54.

may result from an orderly arrangement of stream segments, trees, depressions, or other features (figs. 74 and 84). This arrangement may be a continuous alinement of geologic, topographic, or vegetation features, but more commonly it is a discontinuous alinement. Because lineations are especially important as expressions of fractures they may indicate areas of considerable economic significance.

Drainage patterns are an important element in geologic interpretation of aerial photographs (figs. 48, 94, and 96). In bedrock areas these patterns "* * * depend for the most part on the lithologic character of the underlying rocks, the attitude of these rock bodies * * * and the arrangement and spacing of the planes * * * of lithologic and structural weakness encountered by the runoff" (Tator, 1954, p. 412). Stream patterns thus reflect the control exerted by underlying structure and rock type. But stream characteristics may be influenced by thickness and kind of surficial material where structural control is at a minimum. Under these conditions the drainage may reflect differences in surficial materials that are significant to the engineering geologist. (See Belcher, 1945, 1948; Jenkins, Belcher, Greeg, and Woods, 1946; Frost, 1946; Frost and Woods, 1948; Hittle, 1949; and Parvis, 1947, 1950.) In areas where resistance to erosion may be more or less uniform, as in many surficial deposits or in bedrock without pronounced structure, the drainage pattern is commonly dendritic or modified dendritic (see figs. 70, 77, and 106). Where structures are well developed, as in folded mountains, characteristic trellis, annular, or other drainage patterns may develop (see fig. 64).

Because the sensitivity of drainage to strike and dip directions is pronounced, changes in a drainage pattern, or deviation from an established norm, may be as important or more important than interpretation of any one stream pattern. "It is therefore important that relatively large areas be examined so that local drainage patterns [or anomalies] may be readily differentiated from regional drainage patterns" (Alliger, 1955, p. 180). A change in drainage may thus have significant structural implications (see figs. 9, 94, and 96). But a difference in stream pattern may also suggest variations in lithologic character of the underlying rocks.

Patterns of vegetation are also commonly of geologic significance and may reflect structural conditions or lithologic character of rock types (see figs. 40, 43, 54, 72, and 85). Woolnough (1934a, p. 213) suggested that a distinction be made between two types of vegetation distribution which he called "blocks" and "alinements;" the former occurs on extensive outcrops of rock of uniform character, the latter along narrow rock bands, faults, or similar limited features. Alinements further may be subdivided as linear, parallel, and curved (see Woolnough, 1934a, p. 213). It is suggested that narrow linear or palallel alinements of vegetation may represent fractures (figs. 50, 60, 71, and 101), whereas wide, curved alinements may signify the distribution of outcrop of low, moderately or even steeply dipping beds (figs. 40 and 72); where curved alinements form closed loops they generally represent horizontal or nearly flat lying beds (figs. 61 and 77).

The term "pattern" has also been used in the literature in quite a different sense than described above. In the study of surficial materials the term "soil pattern" —a poorly chosen term—refers to the combination of surface expressions, such as landform, drainage characteristics, and vegetation, that are used in the interpretation of ground conditions (see p. 34–37). Thus pattern as defined above may be included as an element of the broad term "soil pattern," commonly used in engineering geology descriptions. Soil patterns may reveal information of direct use in engineering geology studies, as in the location of granular materials (figs. 52, 88, 104, and 108; and p. 34–37); in addition soil patterns may be important in suggesting the distribution of certain rock types; this distribution in turn may reflect geologic structures (see figs. 4, 48, and 81).

RELATION TO ASSOCIATED FEATURES

The relation of one feature to its surroundings is commonly important because a single feature by itself may not be distinctive enough to permit its identification. The significance of this relation may be spatial or genetic. For example, depressions may be identified as kettle holes because of their location near readily identified terminal moraines, and because of their genetic association with glaciated terrain. With regard to spatial association this recognition element has also been called the "site factor" (Colwell, 1952, p. 540); it may be particularly useful in determining the significance of vegetation with respect to the underlying geology. For example, certain tree groups growing on topographically high areas in interior Alaska suggest well-drained underlying materials. The landform, especially, in combination with the vegetation characteristics suggests stabilized sand dunes (fig. 56). The relation of associated features may thus permit specific identifications and inferences concerning surficial materials or rock types.

Photograph scale may be important in the interpretation of associated features; that is, a geologic feature on small-scale photographs may be interpreted because of its position with regard to other features,

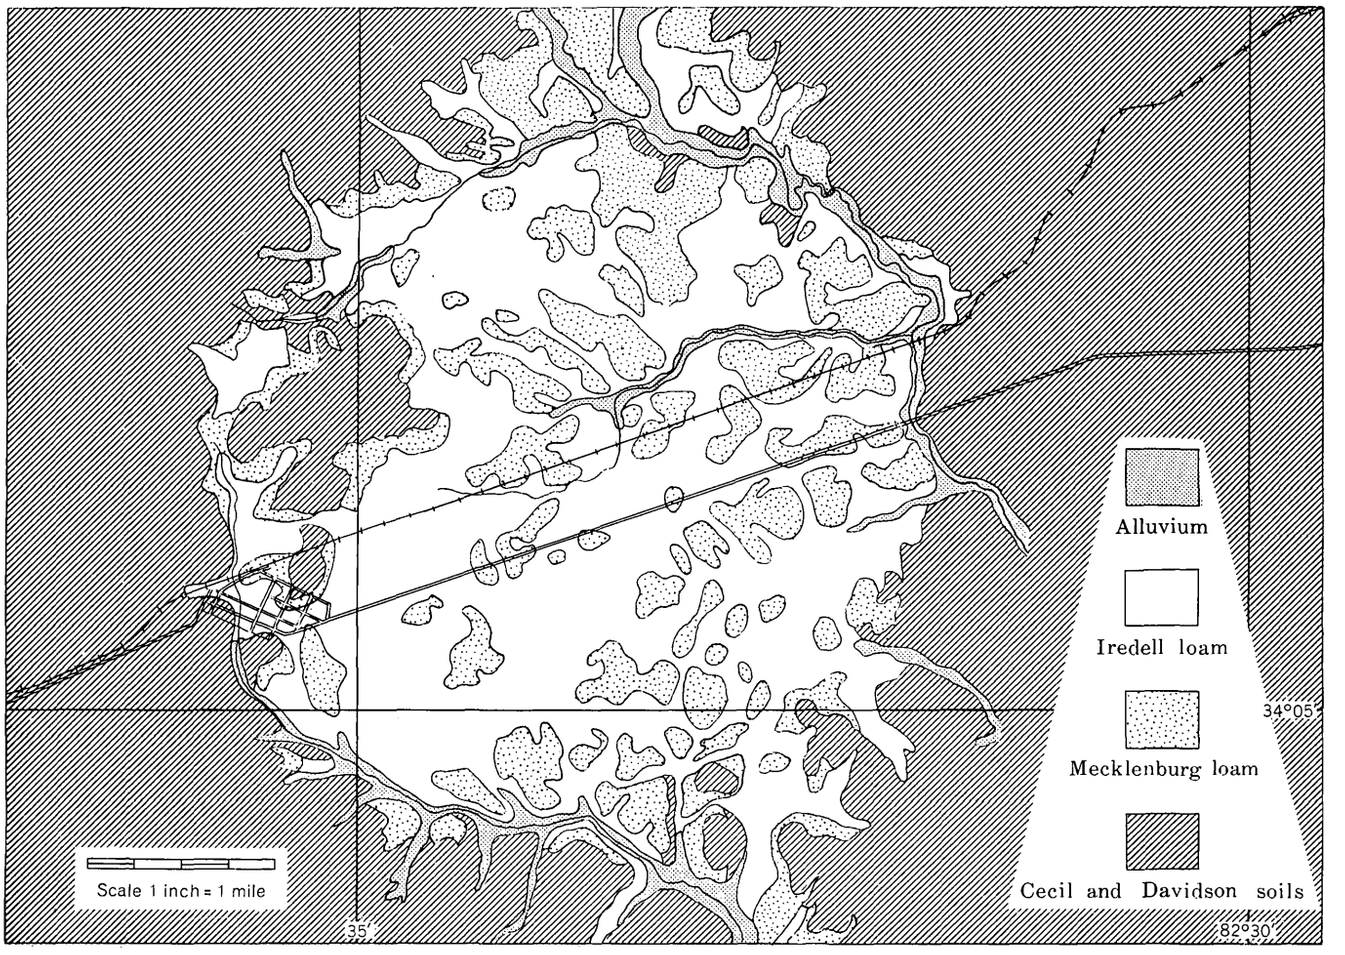

FIGURE 4.—Generalized soil map of area shown in figure 48 (modified from soil survey map of Abbeville County, South Carolina).

The circular area underlain by Mecklenburg loam and Iredell loam is conspicuous. These soils delimit an area of mafic intrusive rocks from a surrounding area of silicic rock types. Particularly where outcrops are sparse or lacking, soil maps may provide significant geologic information, especially in areas of residual soils. The soil maps may provide structural or lithologic data with respect to underlying rocks, or they may provide pedologic data concerning the surficial materials that is useful to the engineering geologist.

all of which can be seen at the same time (fig. 55), whereas on large-scale photographs direct identification might be made because photographic details are visible. The usefulness of association as a recognition element also will vary not only with photograph scale but with the objective of the study. The engineering geologist may be confronted with the immediate identification and location of kames as a source of gravel near a proposed highway route, whereas the geologist mapping the entire area would be interested in the identification, orientation, and distribution of all kames, with respect to geologic history of the area.

SHAPE

Shape as a recognition element in geologic interpretation is significant primarily only in its broadest definition, which involves relief or topographic expression. In this regard shape is very important in recognizing constructional landforms, such as volcanic cones, sand dunes, river terraces, and certain glacial features (figs. 41, 55–58, 60, and 104); it is also useful in differentiating rock units where one formation is expressed in bold cliffs and overlies a second formation that shows a lesser angle of slope (figs. 62, 84, and 91), or where adjacent rocks show significant differences in topographic relief (fig. 65). Rectilinear depressions may be expressions of faults (figs. 60, 85, 86, 99, and 103). The general surface configuration, as in the "beehive" weathering of some massive sandstones, also may be regarded as an expression of shape that is useful in recognition. According to Belcher (1945, p. 140–141)

shapes of gully cross sections are important to the interpretation of surficial materials for engineering purposes. However, in its strictest definition, as "a spatial form with respect to a relatively constant contour or periphery" (Webster's New International Dictionary, 1950) shape has been of little importance as a recognition element because nature may reveal the same geologic feature in an infinite number of different shapes, and because common scales of photography (1:20,000) restrict an interpreter's ability to see details of shape. Where local field criteria have been established, shape may be useful, for example, in the interpretation of patterned areas (fig. 53) or in the study of gully cross sections, particularly when large-scale photographs are available (fig. 88).

Shadow as a recognition element is primarily a use of shape and photographic tone. Because vertical aerial photographs are commonly used for interpretation, shadows may permit an effective side view of some features. For example, shadows may be useful in interpreting tree types, such as conifers, which generally have pointed tops; the type of tree in turn may have a relation to underlying geologic materials and particularly to soil-moisture conditions (Stoeckeler, 1952, p. 4). For interpreting most natural features, however, the shape of shadows probably contributes little in direct identification. Insofar as shadows contribute to textures and patterns, they are of course of great importance. Even slight topographic breaks may be accentuated by shadows (figs. 88 and 97).

SIZE

The quantitative element of size, as it relates to surface or volume dimensions of an object, has been little used in recognition of geologic features from aerial photographs, although relative size has been useful as an interpretation aid. Size as an interpretation element is being used increasingly with the adoption of photogrammetry as a fundamental part of photogeology; it is most appropriately considered in relation to interpretations based on thickness of strata, amount of offset along faults, or other finite measurements (see p. 56–63). Geologically significant measurements may be directly related to topographic expression; that is, measurements between topographic positions may yield direct information such as stratigraphic thickness. But generally other influencing factors, such as dip of beds or other structural elements, must be considered just as in field measurement (see p. 56–58). If the thickness of a formation is known, it may aid in location of formation contacts on aerial photographs, because measurements may be made from known points that would permit the positioning of the obscured contacts (fig. 39); or it may aid in correlation of beds across fault zones. Determining the range of thicknesses over a broad area may be essential to understanding the regional geology of that area (see p. 59–60).

Studies in quantitative geomorphology suggest that size, in terms of finite measurements, may be an extremely important parameter of geologic interpretation of aerial photographs. Measurement of geologic data can be expected to become an even more important part of photogeology in the future as techniques of quantifying geologic information become more widely used.

COMBINATIONS OF RECOGNITION ELEMENTS

The usefulness of recognition elements, of course, is enhanced where they may be used in combination. Indeed, photographic tone, useful alone as a recognition factor under some conditions, is a fundamental photographic characteristic without which there could be no recognition elements at all on black-and-white photographs. As mutually supporting recognition elements an association of photographic tone, topographic expression, and texture may permit the interpretation of bedding, even in areas of sparse or no outcrops (fig. 40). Faults are commonly expressed as straight or gently curved lines; they may be further identified by an abrupt photographic tone change on opposite sides of these lines as well as by a pronounced offset of recognizable rock types (fig. 83). Surficial materials are commonly identified on the combined basis of stream patterns, shapes of gully cross sections, texture, and photographic tone as well as by their relation to associated features (see p. 34–37).

VERTICAL EXAGGERATION

In addition to those recognition elements that are based on factors, such as film and filter used and processing, that directly affect the photographic image, certain other factors are important in interpretation. Especially significant is vertical exaggeration—the exaggeration of vertical distances with respect to horizontal distances—which is characteristic of almost all stereoscopic models; this exaggeration makes slopes appear steeper than they are and objects seem taller than they are. Vertical exaggeration is generally present not only in viewing stereoscopic models formed from paper prints but also in viewing projected stereoscopic models formed from glass-plate diapositives in double-projection instruments.

An understanding of vertical exaggeration is fundamental in the study of stereoscopic models, not only because of the exaggerated heights and the somewhat unnatural view that results, but because in many geologic problems the interpreter relies on visual dip

estimations rather than on any measuring devices (see p. 64). The amount of exaggeration of a dip angle in a stereoscopic model is fundamentally related to the tangent of the dip angle; that is, in a stereoscopic model exaggerated 3 times, for example, any true dip angle would be exaggerated to an angle whose tangent function was equal to 3 times the tangent of true dip. Exaggeration of low dips is generally an aid in structural interpretation and in detecting tilt from aerial photographs.

Minor topographic differences, which may reflect underlying geologic structure, are also exaggerated and in turn easily recognized (figs. 40, 88, and 97). The exaggeration of relief in a stereoscopic model of 1:20,000-scale photographs taken with a 6-inch-focal-length lens commonly permits an interpreter to distinguish differences in altitude as small as 1 foot. As a consequence vertical exaggeration then is most important where small but significant differences in altitude may be present in the stereoscopic model.

Vertical exaggeration results from the wide spacing of the camera positions at the time of exposure, as contrasted to the spacing of the human eyes with respect to normal viewing arrangement in examining stereoscopic models. Vertical exaggeration in normal viewing arrangement is fundamentally related to base-height ratio, which is the ratio of the air base distance to the flying height (see fig. 1). As this ratio increases, vertical exaggeration increases. Thus the greater the distance between camera stations (equivalent to air base distance), flying height remaining constant, the greater is the vertical exaggeration. The resulting photographs will have an increasingly smaller overlap area and consequently a lesser area within the stereoscopic model. It should be noted, however, that in normal photographing procedure when flying height is increased for any given focal-length lens, the air base distance is also increased so that a relatively constant base-height ratio is maintained. Under these conditions vertical exaggeration is not affected by flying height. When the base-height ratio is increased through the use of short-focal-length lenses, vertical exaggeration will also increase, the photographs taken with the shorter focal-length lens showing the greater exaggeration. Effective vertical exaggeration may also be increased by moving the two photographs farther apart at the time of viewing, or by increasing the viewing distance.

SCALE OF PHOTOGRAPHS

Small-scale photographs may be advantageous for interpreting some geologic terrains, particularly where reconnaissance information is desired. Small-scale photographs are normally taken at relatively high altitudes and have scales of 1:60,000 or smaller; their usefulness results chiefly from showing a large area in a single view (approximately 80 square miles on a single photograph having a scale of 1:60,000), which may reveal overall relations, as in geologic structures, drainage patterns, or other features, that could not be readily seen otherwise (figs. 48 and 55). Photomosaics commonly serve this same purpose (fig. 96). The association of features over a large area provided by the small scale is the significant factor to be considered. However, the reduction in image size due to high flying heights or short-focal-length lenses may be detrimental to the identification of some features, and hence make such photographs of little use for some interpretation problems. For example, details of jointing may be entirely lost on small-scale photographs. Also, use of small-scale photographs obtained by using extremely short-focal-length lenses, that is, 2 inches or shorter, may be undesirable, especially in areas of moderate to high relief, because many topographically low areas will be masked from view. Nevertheless, small-scale photographs have definite advantages in qualitative interpretation (Hemphill, 1958b) and may be especially useful if employed in conjunction with large-scale photographs or with instruments that enlarge the photography scale (see p. 47). Where quantitative study is involved, small-scale photographs are advantageous in that less control is needed within a given area than with large-scale photographs; but this advantage may be offset by the decrease in the reliability of measurements (see p. 72–74).

PHOTOGEOLOGY IN GEOLOGIC MAPPING

In geologic mapping maximum use of aerial photographs is attained by closely integrating field and photogeologic studies. It generally is desirable to precede the field phase of geologic study by a study of aerial photographs, which should include the compilation of a preliminary map on which all interpretations, however reliable or questionable, have been noted. Such a preliminary photogeologic study affords several advantages: it may point out areas that must be mapped primarily by field methods; it may eliminate or reduce extensive field surveys in certain areas; it may direct attention to anomalous areas where detailed field study is particularly warranted; and it commonly provides a basis for organizing the geologic plan of field study. In addition, attention is directed to those areas where field study will most likely result in establishing criteria that will permit a refinement of further photogeologic mapping. Also, a preliminary study of photographs gives a geographic familiarity of the area

that would be useful in choosing camp sites, routes of traverse, and optimum locations of instrument survey stations.

Continuing use of aerial photographs during the field phase of geologic study permits a firsthand correlation of geologic features and photographic images, which corroborates or refutes preliminary interpretations and provides information for subsequent detailed photointerpretive study. Refinements in interpretation may be made in the field or in a followup photogeologic study.

The delineation of rock types and structures from aerial photographs may involve mere observation; or more commonly interpretation is involved. In some areas it is possible only to map similar photographic units, as no diagnostic or suggestive criteria as to rock type may be present. Such areas are usually poorly exposed because of heavy vegetation or surficial debris; relief may be very low. But in other areas, where wide expanses of rock crop out, specific formations or rock types may be easily delimited on the photographs; thus much of the routine work of mapping geologic contacts, as well as determining structural measurements, can be accomplished readily by photogeologic methods. Where geologic structures are small and complex, aerial photographs may provide only limited information as contrasted to areas where geologic structures are large and simple. Depending chiefly on factors related to geologic environment, climate, and erosional cycle, the extent to which photogeologic methods can be applied thus may vary widely.

KINDS AND AMOUNTS OF INFORMATION

Geologic information that can be interpreted from aerial photographs may be grouped broadly into two categories: lithologic and structural. In general or reconnaissance mapping the geologist is interested largely in determining the distribution of rock units, including surficial deposits, and in delineating geologic structures. Special studies may require a more rigorous application of photogeologic procedures, which includes quantitative as well as qualitative study of the stereoscopic models. But regardless of the objective of a particular study, the kinds and amounts of geologic information available from aerial photographs will depend primary on the type of terrain—whether igneous, metamorphic, or sedimentary—, the climatic environment, and stage of the geomorphic cycle.

It is generally believed that sedimentary rock areas will yield more information from aerial photographs than igneous rock areas, and that regions underlain by metamorphic rocks will reveal the least information. Putnam stated (1947, p. 560, 562) that "* * * geologic features * * * tend to be more recognizable where strong differences exist in the erosional resistance of adjacent rocks. Thus, sedimentary rocks, as sandstone, shale, and limestone, are likely to be more apparent than relatively homogeneous rocks like granite, especially if the sedimentary rocks have a moderate dip." Bentor (1952, p. 162), based on his work in Israel, was of the opinion that "As a whole, air-photographs are much less useful in regions of crystalline rocks than in those composed of sedimentary formations." With regard to igneous and metamorphic terrains, which are generally believed to be more difficult to interpret than sedimentary terrains, Melton (1956, p. 57) concluded that "Discovery of hitherto unknown or abnormal structures and [mineral] deposits, rather than detailed mapping, will probably be the most rewarding use of aerial photographs * * *."

Except for high mountainous areas where vegetative growth is restricted by altitude, arid and semiarid regions generally will have the largest areas of rock outcrop, and tropical regions the least; hence the arid and semiarid regions may be expected to yield the greatest amount of geologic information from aerial photographs. In addition to relatively wide areas of rock exposure, the arid and semiarid regions may be expected to show a greater number of significant plant-rock associations than other climatic areas, because weathered material in the arid and semiarid regions is not excessively leached and a close relation of soil to parent formation therefore persists. Where this close association of parent rock and residual soils exists the distribution of different vegetation, reflecting the effect of bedrock on the composition of the soils, may facilitate the mapping of different rock types (see Levings, 1944, p. 27–30). In areas of much precipitation, under temperate or tropical climatic conditions, soils tends to be leached of salts, and there is a further tendency for soils from different parent formations to become more similar at maturity (Murray, 1955, p. 104). Murray stated (1955, p. 104) that under tropical conditions where rainfall is abundant, the ratios of potassium, sodium, and calcium to aluminum, which are widely different in silicic and mafic rocks, become smaller on weathering and are nearly equal in mature soils. Thus differences in vegetation as related to specific formations might be less well developed in tropical areas, except for those plant associations that may depend primarily on physical characteristics of the soil rather than chemical. Grantham (1953, p. 329) noted that in semiarid areas of Africa the soils reflect geology through vegetation differences more strongly than in wet temperate areas.

Sedimentary terrains yield a greater amount of lithologic and structural information than igneous and metamorphic areas because of the generally nonhomogeneous nature of sedimentary terrain, which results in marked differential erosion characteristics that stand out on aerial photographs. Sedimentary rocks of strongly differing physical characteristics commonly crop out within short distances whereas plutonic rocks, particularly, are likely to be relatively homogeneous over wide areas. Locally, diagnostic landforms, such as volcanic cones, may be important in study of igneous terrains, especially where extrusive rocks prevail. Metamorphic terrains, on the other hand, may reveal the least amount of information from aerial photographs because of the very nature of the metamorphic processes, which tend to destroy the erosional and landform characteristics of sedimentary and igneous rocks from which the metamorphic rocks are derived.

In any area where vegetative cover is dense and where surficial debris is widespread, aerial photographs generally can be expected to yield more structural information than lithologic information. The amount of structural information in turn generally will be greater, for any one type of terrain and climatic environment, during the mature stage of the geomorphic cycle, at which time streams show their greatest adjustment to and reflection of structure, and at which time a greater third dimension of the terrain is visible for study in the stereoscopic model. Where the lithologic character of rocks is interpreted on geomorphic or landform expression, maturely dissected areas may reveal the greatest amount of information.

Although the extent to which photogeologic procedures contribute to the geologic mapping of an area depends on the climatic and geologic environment, as well as the stage of the erosional cycle, some generalizations may be stated with regard to differentiating and interpreting sedimentary, igneous, and metamorphic terrains. These generalizations are grouped into two categories: lithologic character of rocks and geologic structure.

LITHOLOGIC CHARACTER OF ROCKS

SEDIMENTARY ROCKS

Consolidated.—The presence of bedding in most sedimentary rocks is fundamental to their interpretation from aerial photographs. Because of differential resistance to erosion of sedimentary beds the typical banded patterns of these rocks are seen on aerial photographs. This is a result of what Rich (1951, p. 189) termed the "etching concept" wherein more resistant beds are brought into relief and less resistant beds lowered as a result of weathering and removal of materials largely by sheet wash and creep (figs. 87, 91, and 97). Back slopes of steeply dipping beds, especially, may contrast strongly because they commonly expose to erosion within a given area a wider variety of lithologic types than dip slopes of gently dipping beds. Although topographic expression is thus important in recognition of bedding, banding due to vegetation or soil differences, expressed by photographic tone may likewise delineate beds, in absence of topographic expression or in combination with it (figs. 40 and 81). Bedding is especially prominent in the mature stage of the geomorphic cycle, particularly in terrain underlain by interbedded hard and soft sedimentary rocks that are tilted. However, bedding may be masked by the massive character of some sedimentary rocks, such as certain sandstones, in which case the sedimentary rocks may appear to be homogeneous and similar to some metamorphic rocks or intrusive igneous rocks as seen on aerial photographs (contrast figs. 71 and 92). A notable exception is massive limestone in which sinkholes have developed (fig. 68).

As seen on aerial photographs shales and similar fine-grained sedimentary rocks tend to have relatively dark photographic tones, a fine-textured drainage, and relatively closely and regularly spaced joints (figs. 49, 62, 63, and 91). Coarse-grained clastic rocks, in contrast, tend to have relatively light photographic tones, a coarse-textured drainage, and relatively widely and regularly spaced joints (figs. 42, 91, and 92). These generalizations are probably most applicable to marine sedimentary rocks. However, some fine-grained clastic rocks may be light toned and some coarse-grained sedimentary rocks, such as the continental red beds, may be dark colored rather than light colored and be expressed as relatively dark photographic tones on aerial photographs. Drainage density in a given climatic area is related primarily to resistance of a rock to erosion; drainage density increases with decrease of resistance to erosion. Resistance to erosion in turn is fundamentally related to permeability; generally resistance to erosion is less in rocks of low permeability. Hence, fine-grained clastic rocks commonly have a fine-textured drainage (fig. 79).

Physico-chemical precipitates are in many places closely associated with fine-grained clastic sedimentary rocks; where these rocks are interbedded the drainage texture and joint pattern both may be fine, as with fine-grained clastic rocks alone, but photographic tone of physico-chemical precipitates may commonly be relatively light, as with some fresh-water limestone, rather than dark, despite the fine grain size.

Although fine-textured drainage commonly characterizes nonresistant fine-grained sedimentary rocks and coarse-textured drainage suggests resistant coarse-grained sedimentary rocks, drainage is probably more significant as an indicator of structure than it is of lithology. Drainage characteristics may suggest broad rock groupings, but no one drainage pattern is diagnostic of sedimentary rocks, although annular and trellis drainage generally suggest sedimentary rocks or close metamorphic equivalents. The association of specific drainage characteristics with rocks of certain lithologic or physical characteristics presents an interesting field of study; quantitative study of stream data measureable from aerial photographs, such as drainage density, may indicate certain drainage-lithology relations.

The type of vegetation may be useful in differentiating specific rock types (see figs. 43 and 61). Hemming (1937) noted that striking vegetation differences were exhibited by limestone and quartzite in northern Rhodesia where the trees *Acacia* and *Albizzia* grew on limestone and *Brachystegia* and *Isoberlinia* grew on quartzite.

Unconsolidated.—Most surficial deposits—the unconsolidated sedimentary rocks—are readily distinguished on aerial photographs from consolidated rock types, although thin veneers of surficial material may be difficult to identify. Many recognition criteria are used in identifying and interpreting surficial deposits from aerial photographs, but the most significant criterion is probably landform. Landform is significant because many surficial deposits, particularly those useful to the engineering geologist, are transported materials that have diagnostic topographic form. The importance of landform is seen in the identification of sand dunes, eskers, kames, alluvial fans, river terraces, and similar constructional geologic features (figs. 52, 55, 56, 58, and 104). On the other hand extensive deposits of surficial debris, such as the drift plains of north-central United States, may show little or no diagnostic landform, but their general makeup may be inferred from drainage characteristics, photographic tone, analysis of slope, and related criteria (fig. 107). These criteria are discussed more fully under uses of aerial photographs in engineering geology studies (p. 33–37).

IGNEOUS ROCKS

Extrusive rocks.—Extrusive igneous rocks commonly have diagnostic landforms (figs. 41, 60, and 76) in contrast to the intrusive igneous rocks, which are revealed on aerial photographs primarily by other recognition features such as drainage, texture, massive character of the rock, and crosscutting association with country rocks.

In addition to landform certain other criteria may be useful in identifying extrusive rocks, if the terrain is relatively undeformed. The structural relation of flows to associated rocks, for example, may be diagnostic in little-deformed areas, but where flows have been strongly tilted, folded, or otherwise disturbed, recognition and interpretation from aerial photographs may be extremely difficult or impossible. Only those relatively undeformed flows, mainly of Tertiary age and younger, are readily identified from aerial photographs without some knowledge from ground surveys. The ground plan of flows showing lobate patterns of vegetation and topography, especially at the terminations of suspected flows, is commonly diagnostic (figs. 76, 85, and 113), and association with volcanic cones makes misinterpretation difficult (figs. 41, 60, and 76). Locally flow channels may be visible. The surface of a flow may be rather hummocky and irregular, in contrast to surfaces of sedimentary strata, and where several flows have piled up, present topography may show several terracelike forms with irregular surfaces. The unconformable contact between flows and underlying rocks may aid in recognizing extrusive rocks (fig. 87), and where flows cascade down over older topography their identity is obvious (fig. 60). The basaltic or mafic flows may show dark photographic tones on conventional photographs, particularly in well-exposed areas, whereas rhyolitic or silicic flows may have light photographic tones. Locally distinctive patterns are present on mafic flows (fig. 53), and in some areas erosional characteristics permit differentiation of flows and associated rocks (fig. 69).

Where flows have been extruded over deformed igneous and metamorphic terrains, a low-dipping surface associated with lobate patterns of vegetation and topography is suggestive of extrusive rocks, and in some areas faults in the underlying rocks are seen to terminate abruptly at the edge of a lava flow (fig. 85).

Intrusive rocks.—Intrusive igneous rocks have a wide variety of structural relations to surrounding rocks that commonly aid in their identification from aerial photographs. Dikes may be revealed on aerial photographs as rectilinear or curved ridges that stand up because of greater resistance to erosion than surrounding rocks (figs. 81, 82, 87 and 90); they may also contrast in photographic tone with the surrounding rocks either because of the difference in rock types (fig. 90), or because of distinctive vegetation that covers dikes in some areas (Mogg, 1930, p. 662 and 668, pl. 5). Dikes may follow fractures in other igneous rocks and contrast in photographic tone with the host

rock. Where dikes are less resistant than the country rock, they may be expressed as rectilinear depressions that appear similar to fault expressions.

Because sills occur parallel to bedding in sedimentary rocks, they may be difficult to interpret as igneous from aerial photographs, even though strong tonal contrasts of the sills and sedimentary rocks are present. Mogg (1930, p. 656) pointed out that the diabases of Pretoria, South Africa, although relatively hard rocks, weather easily to deep soils that support distinctive deep-rooted vegetation, but the vegetation type differs from area to area. The tree *Kirkia wilmsii* grows conspicuously and exclusively on diabase sheets in the sedimentary rocks of the Pyramid Hills area of Pretoria (Mogg, 1930, p. 658), but in the Magaliesberg area *Acacia caffra* characteristically marks the diabase (Mogg, 1930, p. 662). Vegetation thus may be important locally as an indicator of rock types, but commonly it must be interpreted with caution because the same rock type may carry a different flora in different areas.

Igneous plugs, laccoliths, stocks, and batholiths, by nature of their mode of origin, commonly tilt the sedimentary rocks which they intrude, and in areas where plutonic rocks are exposed the pattern of dips in surrounding rocks may support other criteria suggestive of igneous rocks. Domal areas due to intrusion may also be reflected in radial drainage patterns (fig. 48), just as are certain folds in sedimentary rocks. But if areas of plutonic rocks are large, the characteristic homogeneous nature of such rocks may result in a dendritic drainage pattern, unless drainage is controlled by a fracture system (figs. 51, 70, 71, and 86). Because of the generally homogeneous nature of plutonic rocks as contrasted to sedimentary rocks they will have a massive appearance on aerial photographs, and banding typical of sedimentary and some metamorphic rocks will generally be lacking (figs. 59, 70, and 71). Also because of the homogeneous character of many igneous bodies, elements essential to plant growth may be distributed more or less uniformly throughout the mass (Murray, 1955, p. 103) and significant differences in vegetation can be expected to be absent from any one plutonic rock mass (fig. 70), except for those differences controlled by altitude or by structural conditions, such as faults that may trap an abundance of moisture (fig. 71).

In addition, topographic and erosional characteristics may aid in the interpretation of some igneous terrains. Granite at low altitudes in some tropical areas is expressed in hummocky, rounded topography on which a uniform type of vegetation is present; dendritic drainage may characterize this terrain. Similar rounded topography may also be present at high altitudes, but where glaciers have been active all rocks may stand out in sharply angular topography. Regardless of surface expression, however, a crisscross pattern of joints, nearly always present in igneous rocks, commonly can be seen not only in the well-exposed areas (see figs. 70, 71, 100, and 103) but also in many vegetation-covered areas (fig. 72). Topographic expression of most plutonic rocks, as with other rock types, is dependent in large part on climate and stage of the erosional cycle, although within an area underlain by different igneous rock types difference in resistance to erosion may be significant and specific rocks may stand topographically high (see fig. 82). The homogeneous character of many intrustive rocks and characteristic jointing, on the other hand, are related primarily to the rock type and its mode of occurrence, and are independent of climate and erosional cycle.

METAMORPHIC ROCKS

The identification and interpretation of metamorphic rocks from aerial photographs is commonly difficult because large-scale distinguishing characteristics are generally lacking. Bedding, so necessary to structural interpretation, may be difficult or impossible to recognize because of physical changes brought about by metamorphism, including the superposition of metamorphic structures of small scale. Indeed, many structural trends that can be interpreted from aerial photographs represent foliation rather than bedding (figs. 73 and 74). Where exposures are good, differences in photographic tone offer the best clue to recognition of bedding, especially where the metamorphic rocks are derived from thin-bedded sedimentary rocks of contrasting lithologic makeup (fig. 103). Thick formations of quartzite and marble might readily retain the photographic characteristics of the original sedimentary beds, however, because the metamorphic changes of induration of sandstone and recrystallization of limestone would likely have little effect on the gross physical appearance of these rock types as seen on aerial photographs. It is possible, however, that talus from quartzite ledges might take the form of large blocks in contrast to smaller chunks of rubble at the base of sandstone cliffs. The preference of vegetation for one rock type such as limestone, as a result of its chemical makeup, might well persist, even if the formation were metamorphosed to marble; but vegetation that might show a preference for sandstone because of its physical makeup, especially its high porosity, might well be lacking on its metamorphic equivalent, quartzite.

Strong parallel alinements of ridges and intervening low areas may be due to regional cleavage, foliation,

or fold axes, and thus the "topographic grain" of an area may suggest underlying metamorphic rocks (figs. 73, 76, 100, and 102), but in glaciated areas this evidence must be used with caution (fig. 67). In an area where a pronounced regional trend, or "topographic grain," is shown on the aerial photographs, the likelihood that metamorphic rocks are present is supported by the occurrence of widely spaced lineations at right angles to the regional trend. These lineations commonly represent regional cross joints and may be reflected in abrupt deflections of drainage along conspicuous straight stream segments of major streams (fig. 74) or in the development of tributary streams along these joints (figs. 73–75). Where bedrock is well exposed the profuse fractures in certain metamorphic rocks may be visible (figs. 46 and 99). Cady (1945) pointed out that in some areas in central Alaska talus slopes are developed much more extensively where the peaks are of metamorphic rocks rather than of granitic rocks; this distinguishes these two rock types locally (fig. 103).

STRUCTURE

FLAT-LYING BEDS

Flat-lying or nearly horizontal beds are most easily recognized where different sedimentary rock types exhibit contrasting photographic tones expressed as bands that extend along the topographic contour (figs. 77 and 78). Where both resistant and nonresistant rocks are present slope characteristics commonly are suggestive of horizontal strata—the resistant rocks have steep slopes or vertical cliffs, and the nonresistant rocks have a lesser angle of slope; the significant changes in slope between two beds extend generally along the topographic contour (figs. 77 and 78). Photographic tone and slope characteristics are associated in many places as mutually supporting evidence of flat-lying beds.

Because of the uniform resistance of one rock type to erosion, particularly in a horizontal direction, the drainage on flat-lying beds is generally dendritic unless controlled by joints or faults (figs. 42, 61, and 77). However, dendritic drainage alone, although suggestive, is not necessarily diagnostic of flat-lying sedimentary rocks; other rock types, such as granite, also may be uniformly resistant to erosion and may also exhibit dendritic drainage.

DIPPING BEDS

Numerous expressions of dip of sedimentary beds may be seen on aerial photographs. Dip direction is readily apparent where topographic surfaces coincide with bedding surfaces (figs. 87, 90, 92). Even in heavily vegetated areas the direction of dip commonly stands out as a result of the overall view afforded by the aerial photograph, which shows the tree crowns to fall in a dipping plane (fig. 89). In those areas where dips are very low, the aerial photographs are advantageous, if the beds are clearly expressed, because vertical exaggeration, which is present in most stereoscopic models, permits low dips to be readily interpreted (see fig. 91 and p. 64). The degree of dip may be estimated from the stereoscopic model by experienced photointerpreters or it may be measured photogrammetrically.

Where bedding is expressed by bands of differing photographic tone or by topographic breaks in slope due to resistance of beds, the rule of V's may be applied to determine the direction of dip; that is, where the trace of a bed intersects a stream valley a V in the outcrop pattern will point in the direction of dip (figs. 80, 81, and 98) unless the direction of dip and direction of streamflow are the same and the stream has a gradient greater than the amount of dip (fig. 59).

In many areas, particularly those of low relief, where beds are obscured by surficial materials or vegetation the direction of dip may be inferred from drainage characteristics. Where dips are gentle the relatively long tributary streams commonly flow down the dip slopes (Lattman, 1954, p. 361–365), whereas short tributary streams will characterize back slopes (figs. 5, 7, and 74). It is interesting to note that the relation of short and long tributary streams may be reversed where dips are steep, that is, about 45° or more (fig. 6). Other photorecognition criteria, such as distribution of photographic tones, should be sought to indicate whether dips are gentle or steep; or scattered field observations may provide sufficient information for making an analysis of dip direction based on stream characteristics. In such an analysis it may be desirable to trace all streams, however small, on a separate overlay (fig. 7). This is best done from the stereoscopic model. Exact positioning of tributaries is not essential to this technique of determining dip direction, but lengths of tributaries must be sketched carefully as the length relations of updip to downdip tributaries is significant. Viewing the stereoscopic model pseudoscopically (fig. 95) may be helpful in delineating the drainage.

FOLDS

Folds are commonly expressed as obvious features on aerial photographs especially where a fold is shown in its entirety within a single view and an orderly structural arrangement of beds is discernible (fig. 90) or where erosion has exposed a cross section of the

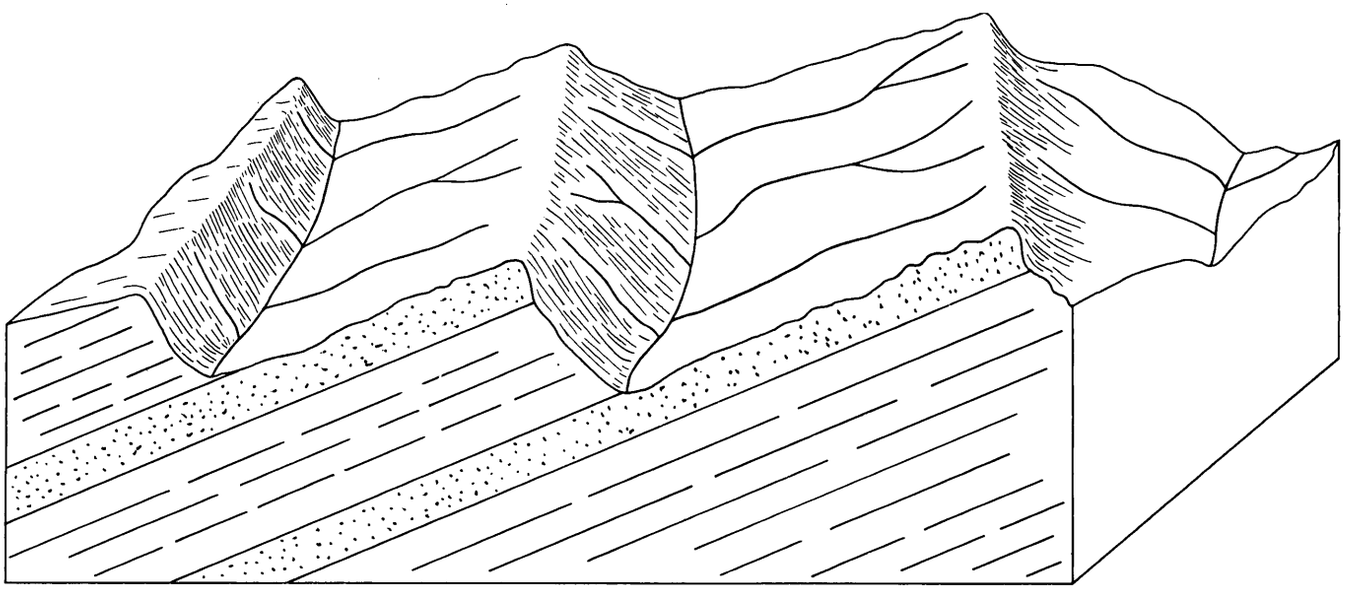

FIGURE 5.—Sketch showing long tributary streams on updip side of strike valley in area of low dips.

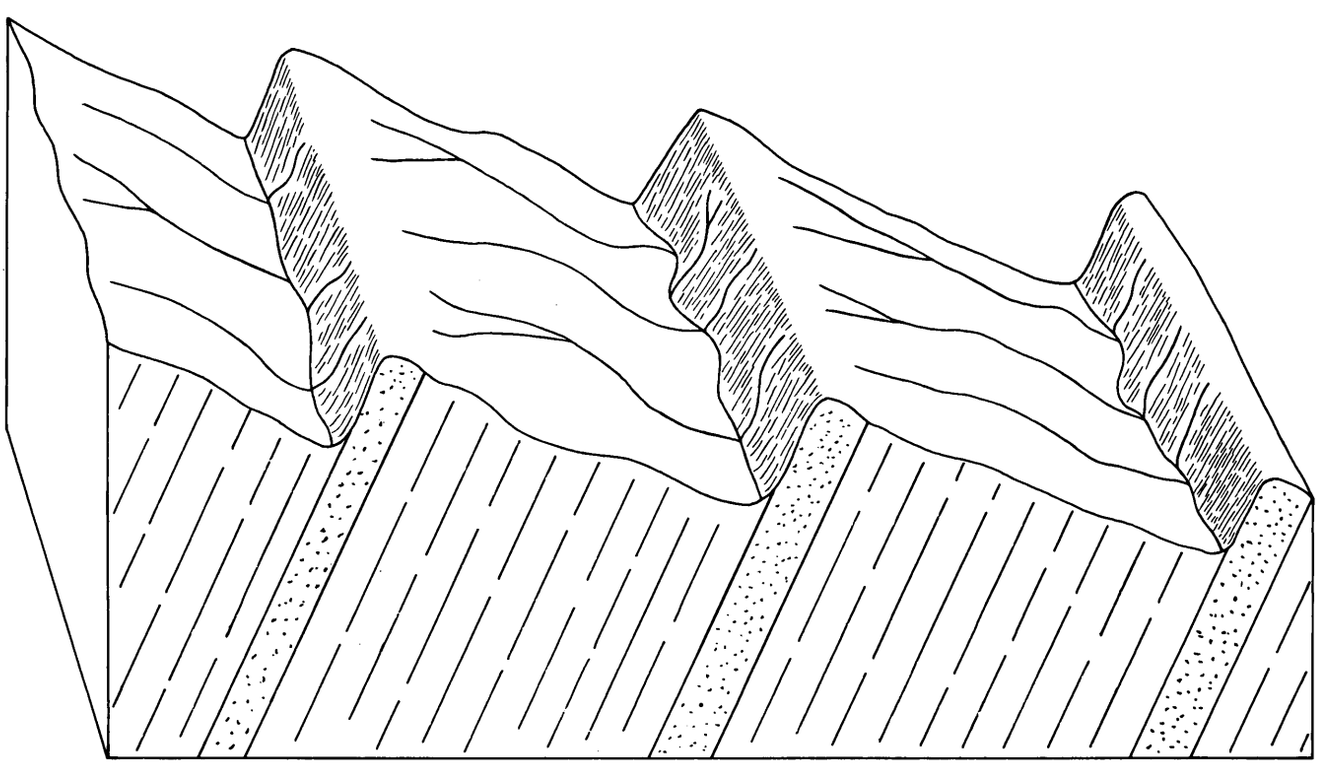

FIGURE 6.—Sketch showing long tributary streams on downdip side of strike valley in area of steep dips.

structure (fig. 91). Drainage characteristics may also aid in recognizing and delimiting the fold. Wengerd (1947, p. 596) noted that in parts of northern Alaska streams flowing in synclinal valleys were sluggish and meandering, and had low banks and swampy border areas with meandering tributaries; in contrast, streams flowing in anticlinal valleys were steep walled and less meandering. Wengerd also noted that dip slopes and back slopes in some areas commonly exhibited different drainage densities (fig. 79).

Where folds are plunging, major streams commonly curve around the nose of the fold; the convex side of the curve indicates the direction of plunge of anticlinal folds (figs. 81, 89, and 90). However, in areas where relief is low or bedrock is obscured by vegetation or surficial materials, drainage patterns or drainage anomalies may be the primary expression of folds (see figs. 9, 94, and 96; and p. 26–27). Drainage patterns or anomalies generally are best seen on small-scale photographs or mosaics where segments of streams combine to form significant patterns when observed in a single view (fig. 96). The significance of drainage characteristics may not be immediately apparent when large-scale photographs are viewed.

FAULTS

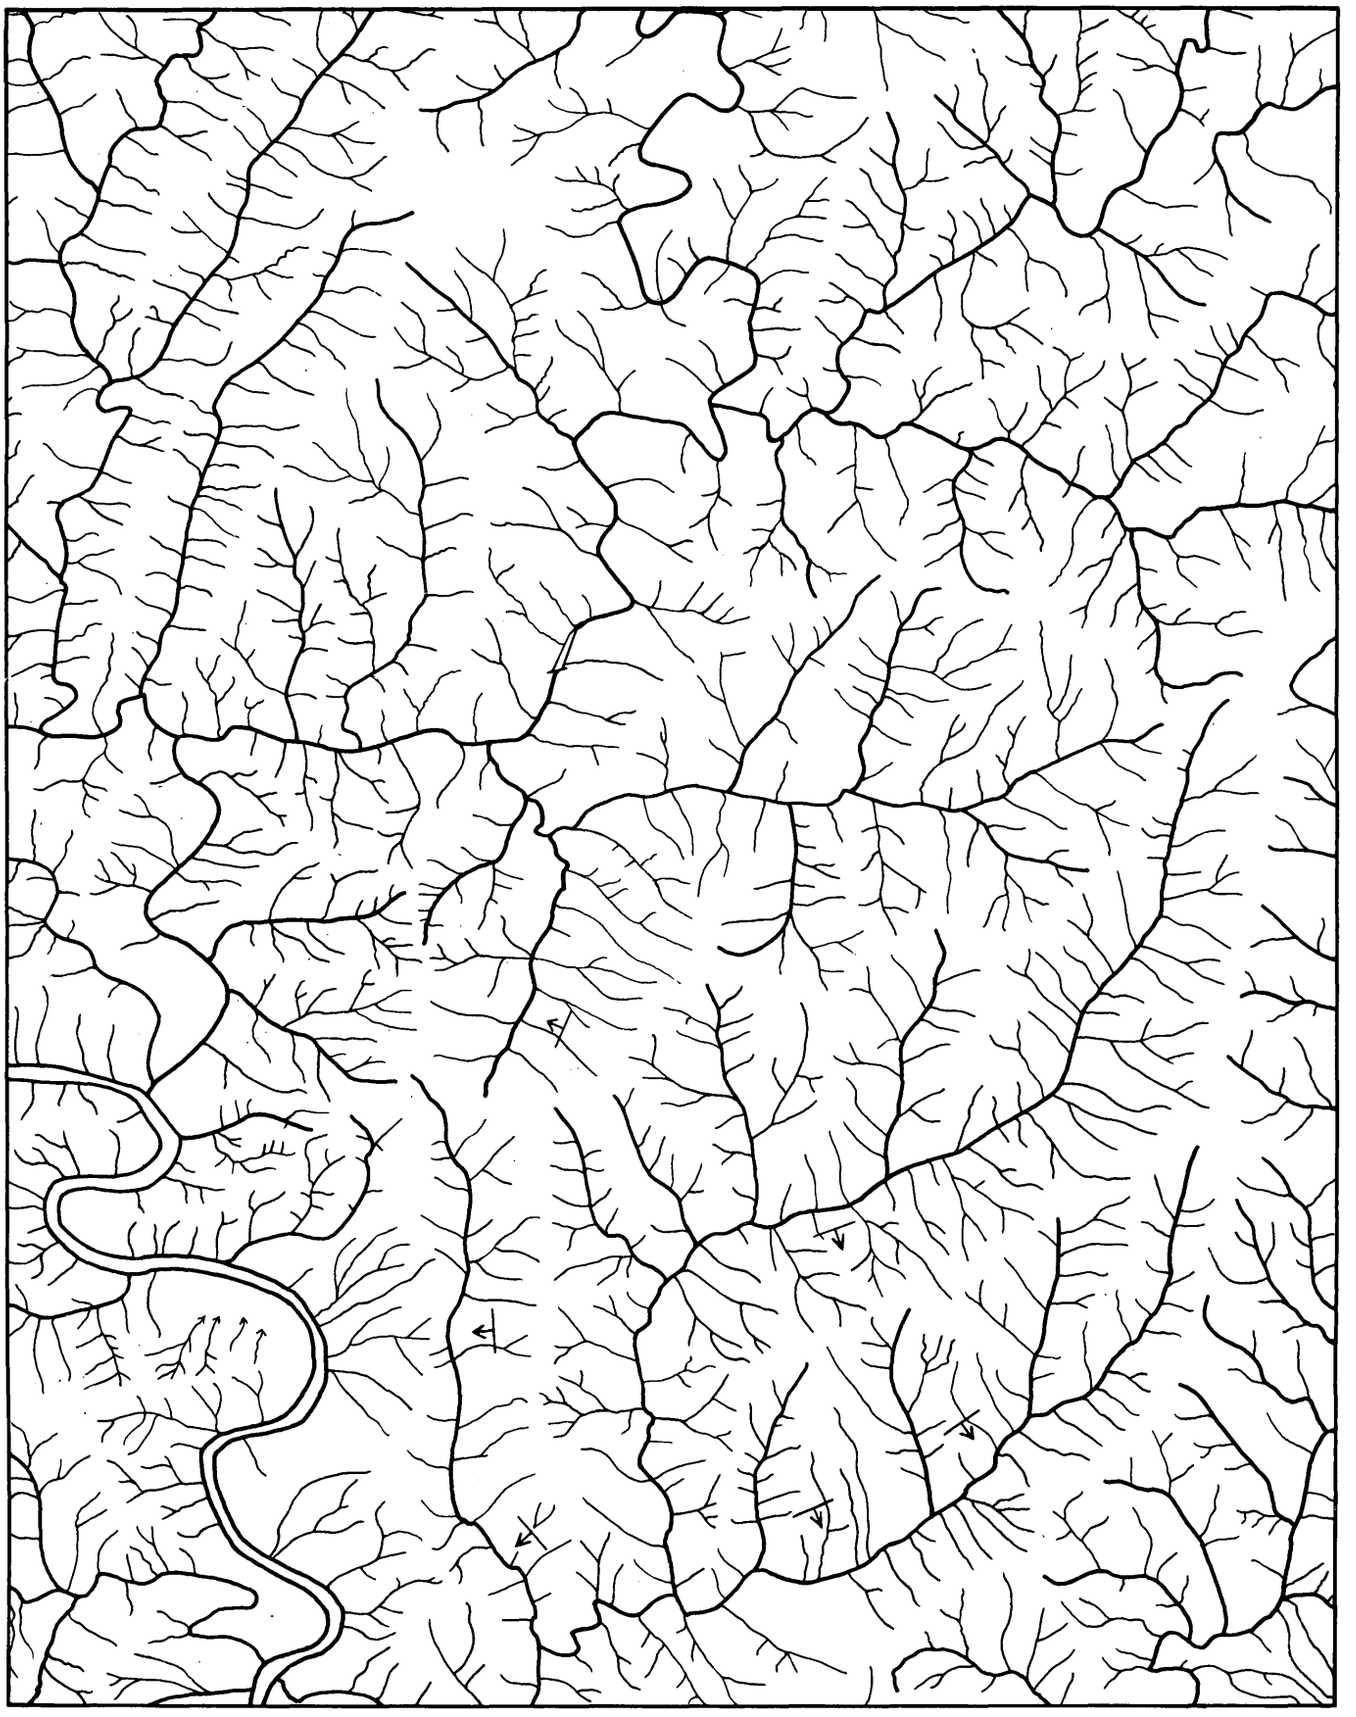
One of the advantages in study of aerial photographs is that of delineating high-angle faults or suspected faults. This advantage is a direct result of the aerial view, which allows a large area and the gross features within it to be seen at one time. For example, many alinements that are inconspicuous on the ground are readily seen on aerial photographs (figs. 74 and 83). Although many alinements are conspicuous because of their independence of stream valleys or ridges and uplands which they cross (see Barton, 1933, p. 1198), alinements of stream segments and small drainage courses are probably the most common indicators of faults. Most high-angle faults are expressed on photographs as straight or gently curving lines, and this characteristic is probably the most important clue that a fault may exist. All linear features should be examined with care even though other criteria are needed to prove the existence of faults.

Lines indicative of faults may be expressed as alinements of vegetation, straight segments of stream courses, and waterfalls across streams; alinements of lakes, ponds, and springs; conspicuous changes in photographic tone or drainage and erosional texture on opposite sides of a linear feature, or tone change along a linear feature because of vegetation which may appear darker; alinements of topography, including saddles, knobs, or straight scarps; rectilinear depressions; or any combination of these. Faults may also be expressed by horizontal or vertical offsets of beds or recognizable rock units (figs. 50, 60, 62, 74, 79, 80, 82–84, 86, 98, 99, 101, and 114). Where bedrock is well exposed the actual physical break may be seen. In some places a lineament, or broad linear depression, may be conspicuous but not distinct. Where such areas of possible faults occur, beds on one side of the general lineament should be examined for change of dip and strike as well as abnormal stratigraphic position with respect to beds on the other side (see fig. 80). Commonly in sedimentary terrain, offsets on opposite sides of a linear feature are easily detected, owing to the vertical exaggeration which is inherent in most stereoscopic models and which generally assists in the identification of correlative beds (figs. 83 and 84).

Suspected faults should be examined carefully because other features may be represented, at least in part, on aerial photographs in the same manner as faults, particularly if a single photograph is being viewed. In some areas jointing in one direction within a formation may be prominent and where an apparent offset is present owing to the occurrence of an erosion scarp along a joint plane, the scarp line may be misinterpreted as a fault trace. Where channels have been cut in sedimentary formations, and a rock type of different lithologic character now occupies the channels, a distinct lineation between the channel filling and the original sedimentary rock, now truncated, may suggest a fault trace. A line between two distinct types of vegetation, although possibly reflecting the presence of a fault, may well be due to differences in underlying rock types in normal sequence, or to the moisture content of the soil, or even to manmade features. In some areas the simple erosion of dipping strata may result in an alinement of topographically high points that suggests a fault. Or vegetation and drainage alinements may be present along easily eroded dikes. The need for caution in interpreting faults from aerial photographs is thus dictated by the very presence of numerous other geologic features that are expressed photographically in a similar manner.

Low-angle faults are more difficult to interpret from aerial photographs than high-angle faults. Discordance of structures within different rock types combined with strongly curving or irregular traces of the fault contact of the rocks involved offer the best clue to the presence of low-angle faults. Angular unconformities may show similar photographic expression.

In a study of azimuth, frequency, and length measurements, Gross (1951) demonstrated that in some covered areas of the Canadian Shield certain lineations very likely represent faults. The study involved the



construction of histograms in which the length and frequency of topographic lineations as seen on aerial photographs were plotted against geographic orientation within 10° segments of the compass. Similarly, histograms were plotted from a sampling of field data of strike of strata, schistosity, dikes, glacial striae, faults, and other features considered to have a bearing on the configuration of the topography. One peak on the histograms compiled from aerial photographs was found to represent a direction of prominent faulting.

JOINTS

Joints, like faults, are most commonly expressed on aerial photographs as linear features. In flat-lying or gently folded sedimentary rocks, most joints are steeply dipping or vertical, evenly or regularly spaced, and commonly consist of two prominent sets that are expressed on aerial photographs as lines intersecting approximately at right angles, which gives a blocky appearance to the topography (fig. 42); however, joints may be well developed in only one direction, which gives a strong linearity to the fracture plan (fig. 92). In fine-grained clastic rocks the joints are generally more closely spaced than in coarse clastic rocks. Joints may become widened through weathering and erosion processes and appear as particularly conspicuous linear features; the similarity of these joints to faults is superficially striking, especially where well-developed regional cross joints have formed in metamorphic rocks and other criteria of faulting are lacking. Identification of many joints is enhanced by the presence of vegetation along them, due perhaps to greater moisture along these lines. Lattman and Olive (1955, p. 2087) described the use of solution-widened joints in Texas as a guide to indicate steepening of dip and to locate changes in dip direction. Joints more nearly parallel to the dip direction were widened by solution of meteoric water. Rubble, soil, and water trapped in these joints gave rise to dense vegetation expressed on aerial photographs as conspicuous, even-spaced parallel lines. A good clue to the identification of joints in relatively undisturbed sedimentary rocks is the general abundance of short lineations on a photograph, and a more or less uniform trend of these lineations within a given area of a few square miles extent.

Lattman and Nickelsen (1958) described azimuth-frequency measurements from aerial photographs in a study of fracture traces in western Pennsylvania. The fracture traces are expressions of natural linear features that consist of topographic, vegetation, or soil

FIGURE 7.—Drainage map of area shown in figure 74 and vicinity. (Strike and dip positions based on analysis of stream-length relations.)

The separate drainage tracing allows a study of drainage characteristics divorced from the abundant imagery of the photograph. Patterns and tributary stream-length relations, for example, are readily observed on the separate tracing. Relative lengths of tributary streams at many places might easily be overlooked in the stereoscopic model. However, a study of the planimetric disposition of streams must be considered a supplement to a study of the stereoscopic model in which significant features in the third dimension, such as elongate hills or other features that may represent structure, are seen.

alinements exposed continuously for less than 1 mile. The term "fracture trace" is used by Lattman (1958, p. 569) to differentiate these alinements from natural linear features exposed continuously for at least 1 mile or more, called "lineaments." A histogram of frequency and orientation of the fracture traces showed maximums closely corresponding to those of prevailing directions of joints as seen in the field, with the exception of one fracture-trace maximum which had no counterpart in exposed rocks of the area (Lattman and Nickelsen, 1958). This one maximum of frequency and orientation of traces, however, was found to correspond with joints in underlying coal beds; the joints apparently were reflected through an overlying thickness of shale and sandstone to be expressed at the surface in a manner discernible on aerial photographs but not in routine field-mapping procedure. The close correspondence of fracture traces and joint directions in the test area suggest that aerial photographs may be used to extend mapping of joints into nearby areas of no outcrop.

Joints in igneous rocks are likely to be seen readily on aerial photographs (figs. 70, 71, 100, and 103). Commonly three and sometimes four prominent joint sets are developed. Where these joints are primary joints, dips may be low, moderate, or steep, depending on the orientation of flow structures within the igneous mass; this contrasts with the generally steep dipping joints of little-disturbed sedimentary rocks. Because of the wide range of dips of joints in igneous rocks, and because at least three joint sets are almost always developed, the surface traces of these joints, shown as lineations on aerial photographs, intersect at widely varying angles. The resulting crisscross pattern is distinctive of intrusive rocks in many areas. Joints in igneous rocks also may be irregularly spaced in contrast to those in sedimentary rocks.

Joints in metamorphic rocks may not be as conspicuous on photographs as joints in sedimentary or igneous rocks. Joints previously formed in igneous or sedimentary rocks may be destroyed by metamorphic processes and much of the energy of metamorphism spent in development of schistosity, fracture cleavage, or other small-scale metamorphic structures, rather than conspicuous joints. This is particularly true of metamorphic rocks formed from fine-grained clastic rocks, which comprise more than 50 percent of the sedimentary rock group. Where metamorphic rocks are recognizable by strong lineations that represent fold axes or trend of foliation, widely spaced regional cross joints perpendicular to the fold-axes direction may be prominent; streams developed along the cross joints accentuate these structures (figs. 8, 73, and 74).

CLEAVAGE AND FOLIATION

Cleavage or foliation, which is almost universally present in metamorphic rocks, especially in those that were originally shale or other thin-bedded clastic rocks, is difficult to differentiate on most aerial photographs. The "grain" of metamorphic terrain as expressed on aerial photographs by stream and vegetation patterns, as well as by parallel ridges and gullies, however, may well reflect pronounced cleavage or foliation (figs. 76 and 100). Turner (1952) pointed out that prominent topographic alinements in the schists of central Otago, New Zealand, are clearly expressed on aerial photographs. These alinements, generally parallel to the trend of *b* lineations, are believed to have resulted from differential weathering controlled by cleavage, foliation, and other elements of the schist fabric.

UNCONFORMITIES

Unconformities are generally difficult to interpret from aerial photographs. An angular unconformity may be inferred from the discordance of bedding, either in strike, dip, or both, at a contact line that has an irregular trace across a wide area. But discordance alone does not prove the presence of a stratigraphic unconformity since a discordance of bedding may be due to faulting, or locally to crossbedding. The areal distribution of rocks or structures as seen on small-scale photographs or mosaics, or after plotting geologic data over a large area, may also suggest the presence of an unconformity. On a local scale, the separation of unconsolidated, nearly horizontal, river gravel from the truncated, underlying strata is a good example of an unconformity (fig. 88). Pediment gravel that overlies truncated bedrock (fig. 45), or channel-fill deposits that truncate the underlying bedrock (fig. 44), may be clearly expressed on aerial photographs.

INTERPRETATION OF AERIAL PHOTOGRAPHS IN PETROLEUM GEOLOGY

Aerial photographs have been widely used by geologists of the petroleum industry particularly in the mapping of many large-scale geologic structures, which are readily recognized on aerial photographs because of direct surface expressions of dipping beds. The use of photogeologic techniques in the search for structures that may contain oil is continuously increasing. However, as the obvious and well-exposed structures in many areas have long been discovered, considerable attention is now being given to indirect, or geomorphic evidence of subsurface structures. In addition, photogrammetric methods for making measurements needed to compile structure contours and to

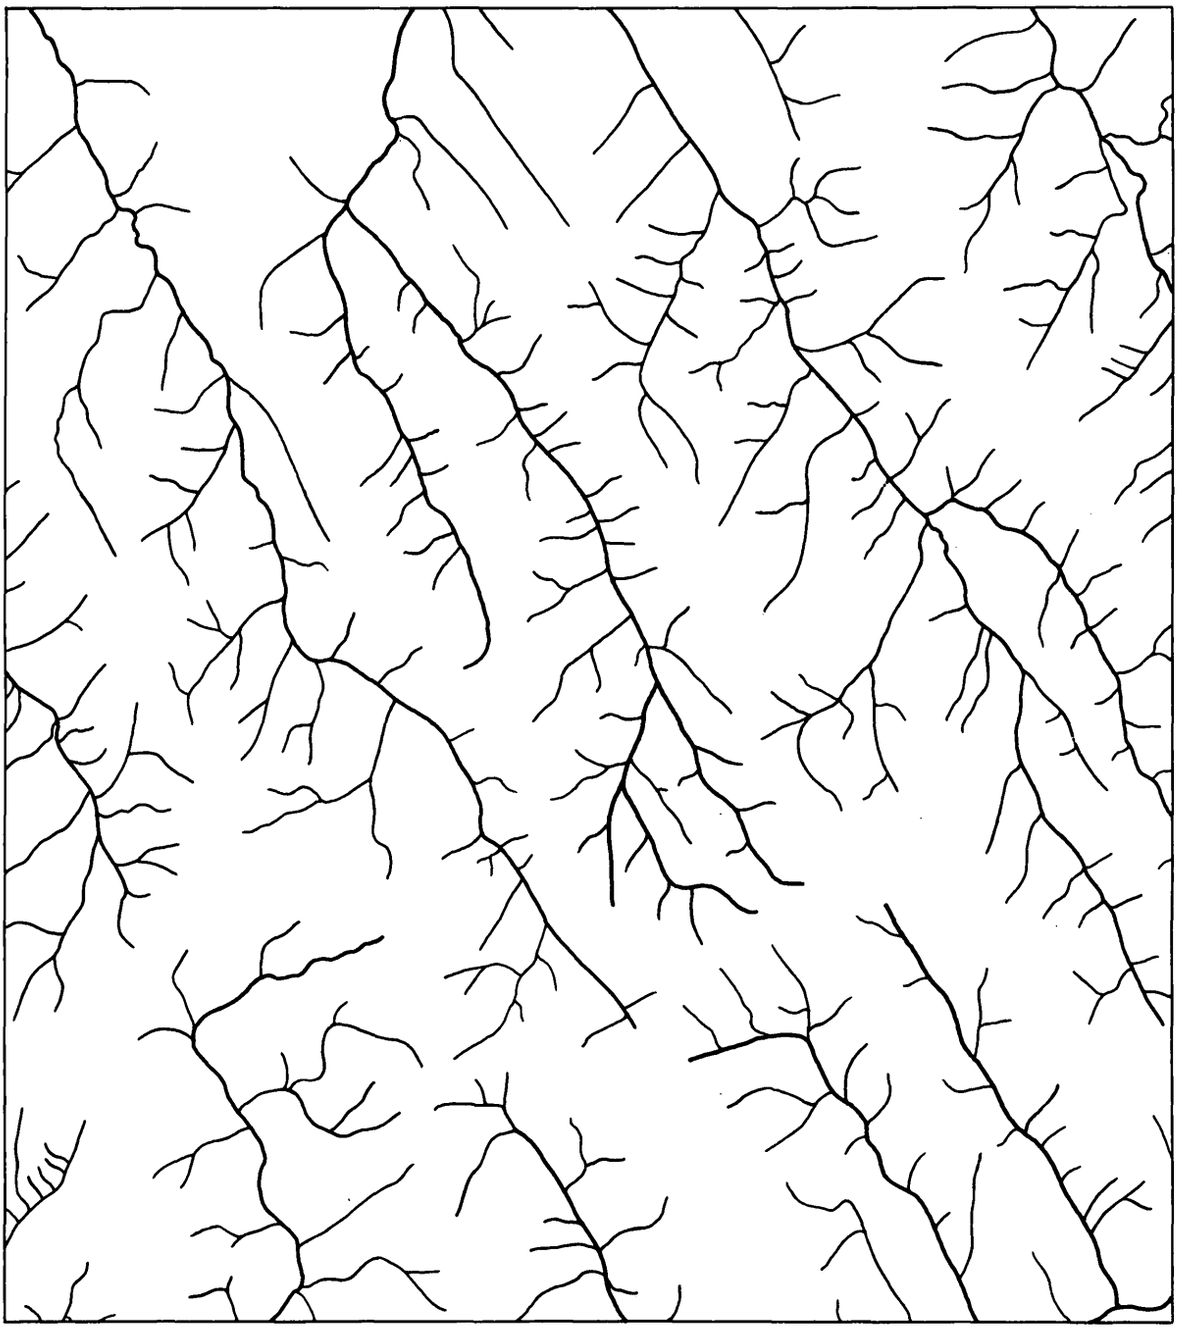


FIGURE 8.—Drainage map of area shown on left half of figure 73.

The regional cross-joint trend, expressed by the main streams on figure 73, is strongly brought out on the drainage map. Note tributary streams flowing at right angles to the main streams. Stream trends are obscured commonly by the abundant imagery of the photograph and it may be desirable to compile separate drainage maps when stream characteristics are used to interpret lithologic or structural features of an area.

determine strike, dip, stratigraphic thickness, and closure are being used increasingly.

The indirect evidence yielded by photointerpretive studies is based on the premise that subsurface structures may be reflected in surface expressions of various kinds, such as stream or vegetation patterns or anomalies. Indirect evidence is particularly useful in the interpretation of areas of few or no outcrops, such as areas of low relief, or areas of dense vegetation. Commonly in such areas, the evidence points not directly to a structure, but to an anomaly, such as a variation in drainage characteristics from the norm established for a local region. The anomaly in turn suggests a possible subsurface structure. Thus even though surface evidence alone may not be conclusive in the interpretation of subsurface structure, it may provide clues and stimulus for exploration (Alliger, 1955, p. 183). However, Wheeler and Smith (1952, p. 112) cautioned that "* * * strong deformation, periodically rejuvenated, is restricted to the mobile belts * * *," and structures farthest away from maximum deformation are "* * * therefore more difficult to infer from physiographic abnormalities at the surface * * * that without the genetic background of those events in the geologic history of the tectonic province responsible for surface and subsurface indications of structure, photogeology may be unfavorably speculative."

FOLDS

Folds may be expressed on aerial photographs by the distribution of bedding, by drainage characteristics, by topography, by distribution of soils, or by combinations of these criteria. The surface manifestations of folded or domed structures thus may range from obvious, where direct surface expression of dipping beds is present, to subtle, where subsurface structures are reflected only indirectly by physiographic criteria.

BEDDING

Many folded structures can be delineated readily because bedding is clearly expressed at the surface. Particularly in areas where rocks are well exposed and structural deformation has been mild, beds may be clearly defined by photographic tone together with topographic relief or hogback landform (figs. 90, 91, and 92); strike and dip of beds are easily determined and the structure delineated from the distribution of beds (see also p. 19).

In areas where bedding may be obscured by low plant and grass vegetation, differences in vegetation together with slight topographic relief changes, enhanced by vertical exaggeration of the stereoscopic model, may permit bedding to be delineated and structures to be structure contoured (see fig. 40 and p. 6).

DRAINAGE

In areas where bedding is largely obscured, for example by vegetation or surficial materials, stream patterns, anomalies, or textures may be helpful in determining dip slopes and outlining folds. In some areas dip-slope streams have a coarse-textured arrangement in contrast to the fine-textured arrangement of back-slope streams (fig. 79). These textures probably reflect coarse-grained and fine-grained rocks, respectively. The distributions of such textures in turn may suggest the location of structural axes.

In many areas stream adjustment to structure will result in a sweeping curve of the stream particularly across a structural axis and around the nose of a plunging fold; the convex side of the curve indicates the direction of anticlinal plunge (figs. 81 and 90). But such curves may also develop on dip slopes and thus not be indicative of the location of a structural axis. This situation may prevail where anticlinal structures are breached into softer material. Streams developing on the more resistant dip slope of the structural flank may curve on that flank and along soft interbeds, and not across the axis of the structure (fig. 93). Such a condition would probably be most pronounced during the mature phase of the geomorphic cycle. In geomorphically young areas streams may not have had sufficient time to adjust to folded structures, and may have a tendency to follow joints or preexisting faults (Howard, 1940, p. 195). In areas where stream pattern or anomaly is the primary surface reflection of underlying structure, as in some jungle-covered areas, other criteria, such as vegetation pattern, should be sought to corroborate the location of a structural axis suggested by stream characteristics.

Stream patterns or anomalies are undoubtedly the most useful indirect evidence of subsurface structures in many areas. This is especially true for coastal areas of low relief, many interior basins, or areas of dense vegetation or other surficial cover. Tator (1951, 1954) and DeBlieux (1949) discussed the structural significance of drainage anomalies in the coastal region of the Gulf States; in these low, swampy areas of aggradation it is important to establish the drainage norm by studying the drainage characteristics over a large area. Deviations from this norm may give the first indication of a structural anomaly. DeBlieux (1949, p. 1259) described abrupt locally restricted changes in drainage considered to be the result of subsurface structure. Over the Lafitte field in Louisiana a relic distributary of the Mississippi River forms two

sharp meander bends, although for miles upstream and downstream from this area, the stream channel is simple and straight. Over the Scully dome "* * * two relic distributaries of Bayou Lafourche followed simple courses, but suddenly changed to an anastomosing pattern over the dome, then resumed simple courses south of the structure." (DeBlieux, 1949, p. 1259.)

Structural implications of stream pattern or anomaly may be corroborated by other geomorphic evidence. Over the Lafitte field the presence of distinct remnants of natural levees on either side of the channel, the only such ridges over the length of the relic course of the stream, was considered significant supporting evidence of underlying structure (DeBlieux, 1949, p. 1259). The levee-ridge remnants presumably were held up by subsurface structure as surrounding areas subsided.

In a study of tonal and textural anomalies in west-central Texas DeBlieux and Shepherd (1951) described anomalous compressed meanders over structural highs. In the same area annular and radial drainage patterns and stream deflections in the flank areas were important criteria that supported an interpretation of subsurface structure (fig. 94). The importance of abrupt changes in direction of streamflow in relation to possible subsurface structures has recently been emphasized by Buttorff (1958) and Elliott (1958), based on work in the Powder River Basin, Wyoming. Such deviations from the norm for an area commonly stand out when a separate drainage map of an area is studied (see fig. 9) or when stereoscopic models are viewed pseudoscopically (see p. 5 and fig. 95).

In areas of aggradation and active subsidence it is to be expected that abnormal drainage characteristics rather than any specific drainage pattern might be indicative of subsurface structure. The combination of emergence, due to recent rise of salt plugs, and subsidence of the general coastal-plain area is responsible for many of the anomalous drainage characteristics of the coastal area of the Gulf States; such characteristics are anastomosing stream segments, abruptly widened levee ridges, or abrupt changes in direction of streamflow.

In areas of active degradation, patterns of drainage rather than abnormal drainage characteristics can be expected to be indicators of structure. However, Wheeler and Smith stated (1952, p. 82) that the analysis of stream pattern with regard to structure—which they called "creekology"—is somewhat outmoded as a photogeologic procedure; they implied that anomalies in drainage characteristics may be far more important than specific drainage patterns. However, drainage pattern may actually be anomalous with respect to the drainage norm for an area; such examples of drainage patterns have been found along the northwest coast of Alaska on the Arctic coastal plain. Here, in an area of northward-flowing streams, slight topographic highs have resulted in radial-dendritic drainage patterns, which outline areas of subsurface structure (fig. 96). Commonly no other surface expression of structure is present. Because of low relief, outcrops are few.

TOPOGRAPHY

The presence of topographic highs has been significant in locating subsurface folds or domal structures even in many areas where relief is very slight. Many of the "islands" of the coastal area of the Gulf States are surface expressions of salt domes. Topographic features such as natural levees, which represent areas of higher ground only a few feet or tens of feet above the delta or flood plain, are also significant interpretation criteria in the search for subsurface structure (Tator, 1951). Tator reported (1951, p. 717) that "* * * cheniers and natural levees * * * provide linear patterns of higher ground supporting distinctive vegetation growths." These higher areas are also favored for cultivation. According to Tator (1951, p. 717) "Tonal contrasts in the photographs are the major keys used for recognition of landscape features of extremely low relief, such tonal variations being largely the result of soil and vegetation differences." The significance of low relief, is shown by DeBlieux's description (1949, p. 1254) of Felicity Island, a 2-mile-long natural levee ridge separated by several miles of marsh from the area where the levees normally could be expected to die out. The preservation of the "island" in an area of active subsidence has been attributed to local subsurface structure. Abrupt widening of levees on one or both sides of a channel, in areas of subsidence, also has been noted over subsurface domal structures (DeBlieux, 1949, p. 1254, and fig. 2, p. 1255); widening of levees may be due to other causes, such as coalescence of two levees, however, and this feature of the flood plain must be interpreted carefully.

In a study in northern Alaska, Fischer (1953) used topography as the principal interpretation criterion in locating the Square Lake anticline. The area is a treeless waste of low relief that is underlain by permafrost; tundra grasses cover the region, and no bedrock is exposed. Fischer (1953, p. 208) reported that the original photogeologic study showed small hills in the area elongate in the same direction as the regional

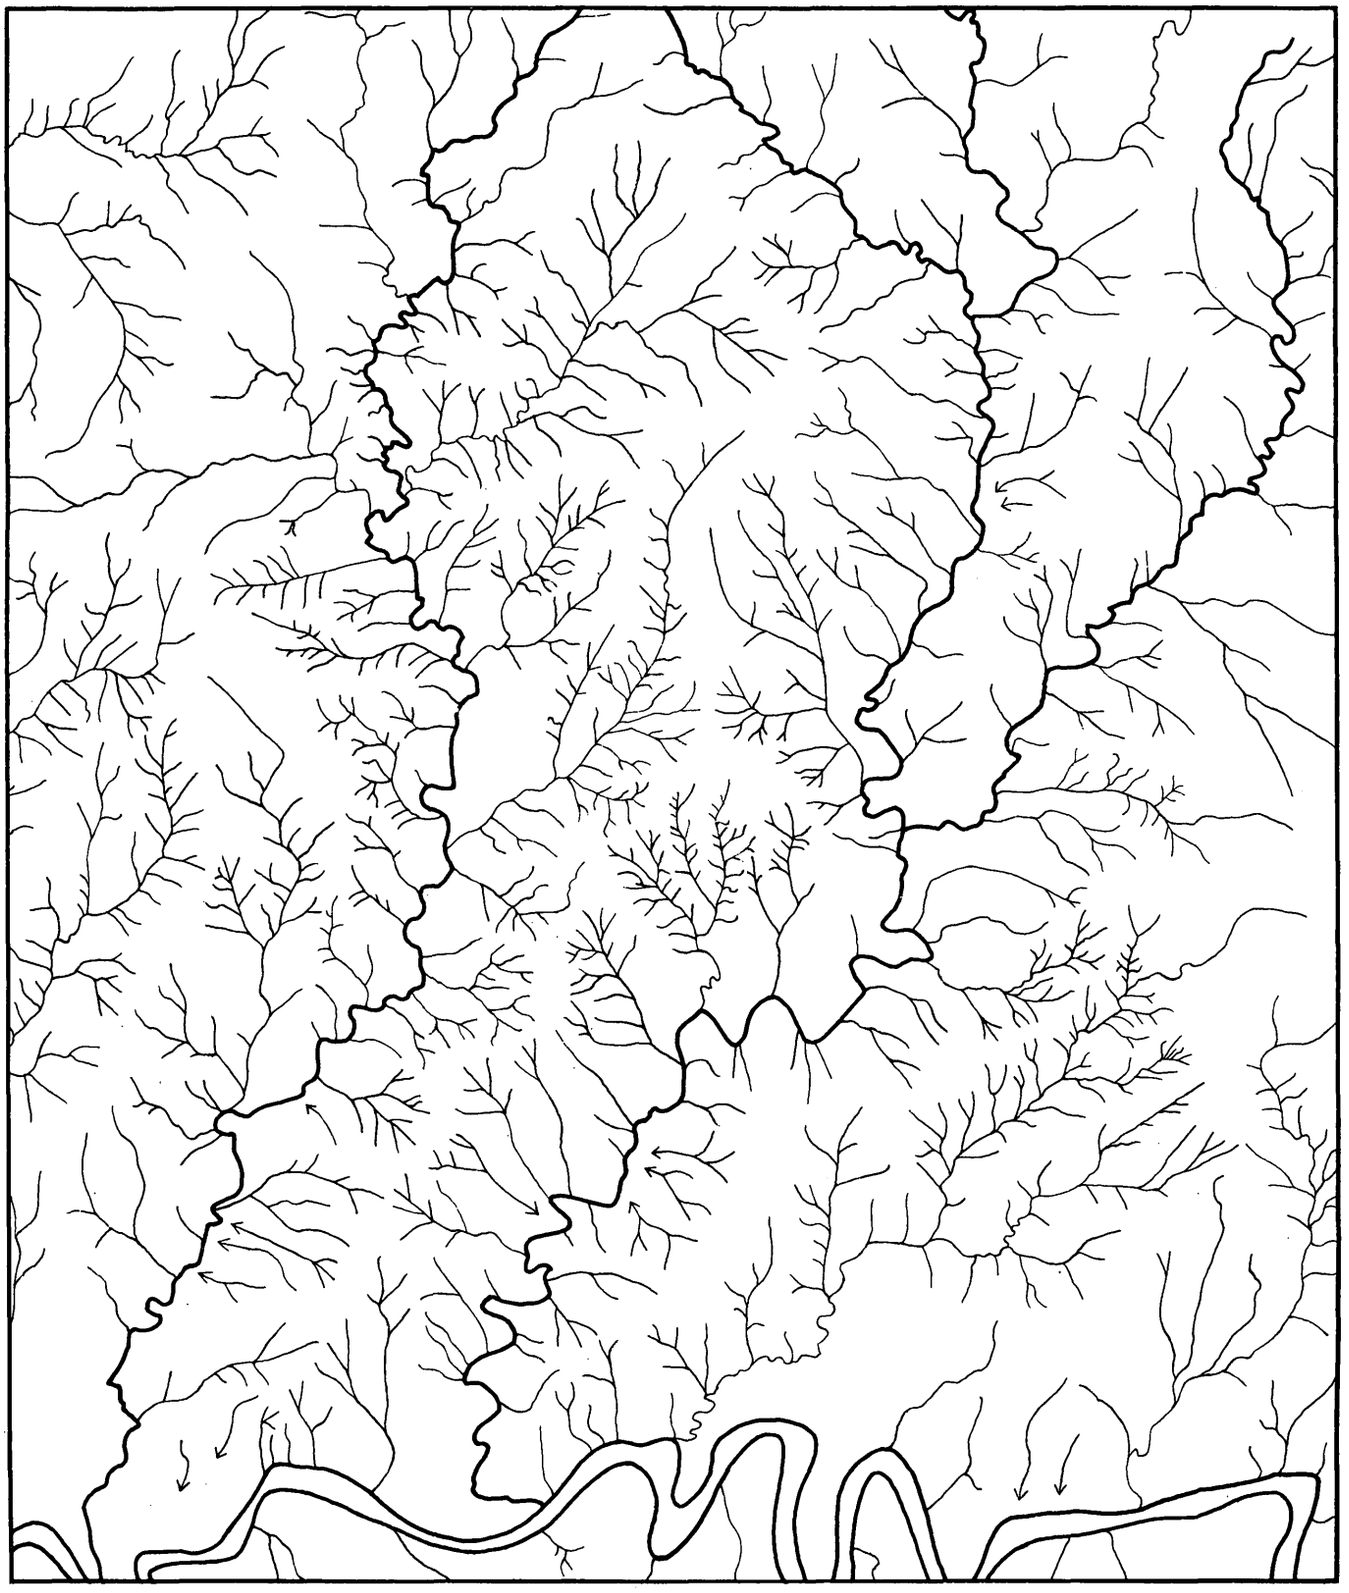

FIGURE 9.—Drainage map of area shown in figure 94.

Radial drainage over structure, *A* of figure 94, stands out on the drainage map which is unobscured by the abundant details of the photograph. Note that the radially draining streams flow into larger streams that have an annular pattern around the structure. Stream deflections, as at *D* in figure 94, are commonly more readily observed on the separate drainage map or in pseudoscopic view of the model (see fig. 95).

structural trend. Normal to this trend other elongate hilltops sloped in the direction of the inferred dip of beds. Also, streams flowing in the dip direction had a slightly less well developed dendritic pattern than those flowing opposite to the dip direction. There also appeared to be a correlation between slopes of the tops of cut banks and the direction of dip. Plotting of all such data gave a consistent apparent structural pattern —a plunging anticline—of unknown reliability. A subsequent seismic survey corrobrated the photogeologic interpretation.

SOILS

In some areas devoid of outcrops, soil patterns or soil distributions may be useful in delineating or suggesting structures. Both Woolnough (1934b, p. 221, 224) and Christensen (1956, p. 858–859) cited examples of the usefulness of aerial photographs in this regard. Wheeler and Smith (1952, p. 106) stated that contrasts in soil tone accentuate unusual drainage relations on the northern flank of a structure in the southwest Maysville area, Oklahoma; and in southwestern Alabama differences in cultivation pattern reflect relief and soil characteristics by which geologic units of Tertiary age beneath younger unconsolidated materials can be differentiated.

DeBlieux and Shepherd (1951, p. 98) described tonal and textural anomalies in west-central Texas that resulted from differences in soil types, soil-moisture content, and erosional characteristics. They cited an anomaly at Salt Fork on the Brazo River where "* * * dark and coarsely hummocky surface strongly contrasts with the lighter color and finer texture of the surrounding surface * * *" (DeBlieux and Shepherd, 1951, p. 98). The anomaly was strikingly similar to that of a reef producer in Scurry County. DeBlieux and Shephard (1951, p. 88) emphasized that how a structure forms is unimportant in a study of tonal, textural and other anomalies, because the surface evidence is identical, whether the structure has resulted from upward movement, differential downwarping, reef or residual topography, or combination of these features; it is important initially that a surface anomaly can be recognized.

FAULTS

Faults are significant in the geologic interpretation of petroleum areas because they may be deep seated and of major importance in localizing oil accumulation. Where faults are genetically related to structures that may be oil bearing the distribution pattern of faults may be of considerable use for interpreting the locations of those structures. The many surface expressions of faults are described above (p. 21).

Desjardins (1952, p. 82) stated that surface fault and fracture lines, expressed as lineations on aerial photographs, form patterns that bear a definite relation to deep-seated salt domes and to subsurface faults of the Gulf Coastal Plain. Disturbance centers, believed to be underlain at depth by salt domes, may be indicated by the fault patterns, shown on photographs as "Sharply curving lines which are strikingly concentric" or as "Prominent transverse lines radiating usually from some marginal point rather than from the center of the structure" (Desjardins, 1952, p. 82). Desjardins believed that such fault patterns were the result of continuous application of small stresses caused by rising salt masses rather than an accumulation of stresses that would produce large amounts of movement; he also felt that faults probably would form in interdome areas as well as over the domes. The genetic significance of the fault pattern is thus critical if distribution of faults is used as a basis for locating the dome itself. Desjardins (1952, p. 83) made a strong distinction between surface expressions of faults, which he associated with deep-seated domes, and other criteria, such as topographic expression, widening of natural levees, and looping of stream channels, which he associated with shallow-seated domes.

Although most interpretations of faults are based on qualitative characteristics of observed data, such as the dislocation of correlative beds, or the contrast in light and dark photographic tones on opposite sides of a straight line, a quantitative approach to such studies may provide additional useful data. On the basis of azimuth-frequency studies Blanchet (1957, p. 1748) suggested that structural and stratigraphic anomalies in some areas may be located by a statistical analysis of fractures, which he defined as the generally abundant, natural lineations discernible on aerial photographs. The basis for analysis is a comparison of local deviations in the statistical mean direction of fracture sets with regional norms for each fracture set. Regional norms are first established by plotting fracture-azimuth frequency diagrams of the region involved. Then statistical mean directions of fracture sets are determined by analyzing samples within circular areas centered at relatively small horizontal intervals of a few miles. These local mean directions are in turn studied for local deviations which are entered into empirical equations that yield structure-intensity values. These structure-intensity values are then contoured, to form a structure-intensity map, which may reflect structural anomaly. The structure-intensity map is supported by a fracture-incidence map, prepared in contour form, and by an analysis of drainage characteristics of the area in question. Blanchet applied this method to a study of petroleum structures.

FACIES

Although the widest application of aerial photographs in petroleum geology has been with regard to structural traps, a study of aerial photographs may contribute to the location of stratigraphic traps, particularly if photogrammetric measurements of formation thicknesses can be made at many points within the streoscopic model (see p. 59–60). From a qualitative standpoint it can be seen in figure 97 that a rapid loss of sandy section can sometimes be detected on aerial photographs. Such "shaling" or loss of sandy section due to facies change may be important in the search for stratigraphic traps and in some areas it may be measured photogrammetrically. In other areas well-defined formational units may thin or thicken without facies change, but this also may be significant in regional studies with regard to stratigraphic traps (Christensen, 1956, p. 861, fig. 6). Measurements of stratigraphic sections needed in such studies commonly can be made from aerial photographs.

REGIONAL STUDIES

The significance of aerial photographs in regional petroleum studies is widely recognized, but very little information is present in the literature with regard to this phase of photograph use. Not only may measurements be made from aerial photographs with regard to strike, dip, stratigraphic thickness, and closure, but the regional view of the mosaic or small-scale photographs permits a continuity of photographic criteria that may be of structural or stratigraphic significance. Overall geologic relations are brought together, and areas where detailed study is needed may be indicated. However, the limitations of the photogeologic technique must be constantly borne in mind. As Wheeler and Smith (1952, p. 112) pointed out, the validity of the technique "* * * depends a good deal upon the human element and the utilization of all applicable geologic data." They warned that "* * * the student of photogeology may * * * become overly impressed with geometric design of lines, masses, and tones so that, in the absence of understanding of the tectonic history he may find compatible alignments of stream courses, structurally inexplicable lineations or shapes and soil patterns that are not consistent with the known or expectable products of diastrophism" (1952, p. 112). An emphasis on regional study is indeed justified, however, if maximum use is to be made of aerial photographs, and this is true whether photographs are used in long-range exploration programs, as in reconnaissance mapping of broad basin areas, or in the ultimate study of local structures.

INTERPRETATION OF AERIAL PHOTOGRAPHS IN SEARCH FOR ORE DEPOSITS

The search for ore deposits, similar to that for petroleum, requires favorable host rocks or structures, or both, and it is therefore necessary to determine the general lithologic character and distribution of rocks and associated structures as a basis for carrying out a mineral survey of an area. Aerial photographs may contribute geologic data not only with regard to the fundamental guides of lithology and structure in ore search, but they also may reveal details of physiography, which may be an important ore guide in the search for placer deposits. Botanical guides to ore bodies may also be detected on aerial photographs of some areas, although little work has been done in this field.

STRUCTURAL GUIDES

Where fractures have been significant in localizing ore deposits aerial photographs may reveal significant structural data relating to trends and offsets of fractures, even in areas where surficial cover is extensive. This is due in large part to the great variety of criteria suggestive of fractures (see p. 21). In many areas it is possible to determine spatial relations of sets of fractures, and to infer the relative ages of the fractures from the aerial photographs, although results of field study are necessary to determine the significance of the patterns.

Aerial photographs are presently most useful in study of those ore deposits associated with fractures. In many mining districts where mineralized fractures form a vein pattern that is repeated throughout the district, an analysis of the fracture pattern and distribution may provide significant data in the search for new ore bodies. Reed (1940) described the use of aerial photographs in a mineral-deposits study of the heavily timbered Chichagof mining district of Alaska where gold-bearing quartz veins are associated with faults and shear zones (see fig. 99). There the faults are commonly expressed as depressions owing to greater erosion of soft material from fault zones (see also Twenhofel and Sainsbury, 1958, p. 1433). Reed (1940, p. 44) stated that many faults of moderate surface expression would probably have been overlooked on the ground, and that many faults of weak surface expression were seen only on aerial photographs. Joliffe (1945, p. 604), in a discussion of photogeologic prospecting in the Yellowknife area of Canada, noted that some of the largest gold-ore bodies "* * * lie in strong shear zones that are marked by rather distinctive gullies in relatively massive, resistant volcanic rocks." Many of these shear zones and other lineaments are conspicuously shown on aerial photographs.

Gross (1951) pointed out that in the glaciated Drysden-Kenora area of northern Ontario and the Goldfields area of northern Saskatchewan, Canada, there are many linear features seen on aerial photographs but that only certain ones represent faults. He devised a scheme of statistical analysis to show the likelihood that certain linear trends were faults (see p. 21). Concentration of prospecting along these linear features in the Goldfields area resulted in discovery of pitchblende deposits.

Because faults commonly are interpreted readily from aerial photographs, photogeologic study may aid in locating extensions of faulted ore bodies. Faults that offset an ore body may show an orderly spatial arrangement, and information regarding direction of displacement may be extrapolated to similar faults whose displacement is masked by vegetation or surficial debris. Willett (1940) found that aerial photographs provide significant information on the location of faults cutting the Invincible Lode, a gold-quartz deposit in the Glenorchy district of New Zealand. The photographs strikingly show the offset of a lode east of the Invincible Lode by a series of parallel faults, which suggest that similar conditions exist at the Invincible Lode where the evidence is not as readily observed because of surficial debris. In the Invincible Lode area one major stream flows parallel to the strike of the faults, and a second stream is deflected along a fault for about 1,000 feet, then bends back to its old course; the direction of deflection also indicates the horizontal direction of displacement of the quartz lode. The pattern of displacement, based on photogeologic evidence together with ground evidence, suggests the location of faulted extensions of the lode.

Major anticlinal and domal structures, readily interpreted from aerial photographs of many areas on the basis of drainage characteristics or strike and dip patterns, are with notable exceptions of relatively little importance in ore search. Where folds have been a factor in localizing ore, as in some metamorphic rocks, they commonly are too small or the geology too complex for existing aerial photographs to provide useful guides in prospecting.

LITHOLOGIC GUIDES

Lithologic guides may be considered from the standpoint of the parent and host rocks, or from the standpoint of mineralized or altered zones, which are more appropriately termed mineralogic guides. Photogeologic interpretation of rock types (see p. 16–19) may outline broad target areas of favorable parent and host rocks (fig. 100). Lueder (1953, p. 823) suggested that various locations can be rated on the basis of favorable photogeologic evidence; the most favorable area would become the prime target area for further investigation. Where some local field criteria are available, specific ore-bearing formations may be traced on photographs (fig. 98). At Ross Lake, Canada, the fact that rare-earth-bearing pegmatites of small areal extent were recognizable on photographs was a major factor in the discovery of certain tantalite deposits (Joliffe, 1945, p. 604).

The use of color aerial photography will increase many times the amount of lithologic information that can be obtained from a photogeologic study. This additional information will contribute not only to the reliable interpretation of host or parent rocks, but may permit local guides, such as alteration zones, to be readily recognized. In a study of the hydrothermally altered volcanic terrain near Tonopah and Goldfield, Nevada, information obtained from reversible-type color transparencies was contrasted with data obtained from thin sections of rock types. Kent (1957, p. 868) stated that "In both areas a general correspondence between coloration and alteration was observed. Zones of different coloration within a lithologic unit represent different stages of alteration. Colors of rocks in early stages of alteration are useful in recognizing lithology, but highly altered rocks have the same color within several different lithologic units. The colors associated with highly altered rocks are easily recognized on color aerial photographs; thus their distribution and their relationship to structural features can be studied." In addition Ray (1958, p. 37) wrote that "In one area of altered andesites a pale green color on color aerial photographs was found to represent an intermediate stage in the alteration resulting from partial silicification, with pale green chalcedony, and deuteric alteration and later oxidation of iron opaques. A light color in another zone was found to result from brecciation of dacite and attendant alteration to carbonates. A rather intense orange color was indicative of highly altered zones in all localities observed. However, the orange coloration did not indicate the rock type involved nor the type of alteration present, but rather was the result primarily of weathering of iron minerals following their partial breakdown by deuteric alteration."

PHYSIOGRAPHIC GUIDES

Some ore deposits are topographically expressed or are related to structures, rock types, or surficial deposits that are so expressed (fig. 102). Hence, topography may be considered a guide in ore search, although it does not by itself indicate the presence of ore. Because fractures commonly are topographically ex-

pressed as rectilinear depressions, a possible physiographic guide to ore as interpreted from aerial photographs may be said to exist in many areas. Where fractures have been mineralized, and the vein filling stands in relief, topography may be a useful guide in ore search. However, many mineralized veins are poorly resistant to weathering and erosion, and occur as topographically low areas.

Where topography results in a photographic texture it may be possible to delineate areas of favorable host rocks, as the paraschists in Surinam (Zonneveld and Cohen, 1952, p. 155). Grantham (1953, p. 336) pointed out that in the wet Sierra Leonne area of Africa, the "* * * sharp change in topography from linearly arranged hills, controlled by schist and migmatite, contrasts with the irregular features of structureless granite."

An analysis of the physiography of an area may provide significant information, particularly in relation to placer deposits. As many placers have a complex history, it may be necessary to work out the alluvial history of a valley or valley system for maximum information in locating placer pay streaks. The arrangement and positions of old stream channels may be interpreted from meander scars, oxbow lakes, and different terrace levels that are commonly seen on aerial photographs. Photographs also may provide gradient measurements of present or past streams; this information may be significant inasmuch as placer concentrates occur especially where stream gradients flatten.

Buried stream channels, also the site of some ore deposits, may be interpreted from photographs of some areas on the basis of topographic expression (fig. 101). In many parts of the western Sierra Nevada, Tertiary stream valleys have been filled and gold-bearing gravel buried by younger lava flows. The greater resistance of the lava flows compared with the surrounding rocks has resulted locally in sinuous cappings of volcanic rocks that stand above the present-day stream system. Table Mountain, California (Loel, 1941, p. 384, 386–387), is an outstanding example of basalt capping auriferous gravel of a buried channel.

The location of stream-channel deposits recently has received wide attention in the search for uranium deposits on the Colorado Plateau in Western United States. There the Triassic Shinarump member of the Chinle formation is thicker in channels cut in the underlying Moenkopi formation, which is also of Triassic age. Some channels can be observed directly on aerial photographs (fig. 44); others may be inferred from isopach measurements, which in some areas may be obtained from aerial photographs. (See p. 58–59). The uranium is associated with carbonaceous materials, largely plant remains, scattered throughout the channels.

BOTANICAL GUIDES

Much field and laboratory work has been accomplished with regard to plant distribution and plant concentration of certain elements as indicators of ore. Little has been done, however, on plant characteristics or associations that may be observed or interpreted from aerial photographs, and herein lies a field of research that has much potential. There appear to be three aspects of botanical study from aerial photographs that may contribute to the location of ore deposits. These involve (a) color differences in vegetation brought about by concentration of certain chemical elements, (b) species differences or absence of vegetation owing to concentration of certain chemical elements, and (c) distribution of vegetation suggesting favorable structures or rock types. Color differences in vegetation, due to mineral and chemical concentrations, that may be reflected on aerial photographs have received almost no attention, and offer an interesting field of study. Species differences or lack of vegetation has likewise received little attention in ore search, although Walker (1929, p. 50–51) noted that air search was made for "dambos" as indicators of copper deposits in central Africa. Dambos are open spots in the bush cover, where vegetation does not grow because of the concentration of poisonous copper salts in the soils. Walker noted that the Roan Antelope copper deposit was marked by such a dambo, although the deposit extended beyond the limits of open area. Identification of species from color differences due to concentrations of certain chemical elements may be particularly amenable to detection on color or other special aerial photography.

Plant and tree distribution may be useful indicators of structures or of rock types favorable to ore deposition; vegetation distribution may reflect physical characteristics of the rocks, such as porosity or presence of fractures, although some rocks, such as limestone, may be preferentially covered by a certain type of tree because of chemical concentrations in those rocks (see fig. 72) rather than because of physical properties. Or vegetation may grow preferentially or trees grow higher and be alined along a fault or shear zone, which might in turn be a favorable site for ore deposition (see fig. 71). Such indirect guides in ore search contrast highly, however, with color or species differences, which might suggest more strongly the presence of ore minerals.

Levings and Herness (1953, p. 456–457) stated that heavy timber growth in the Corbin-Wickes area of Montana shows a preference for unaltered quartz mon-

zonite, which has a darker photographic tone than the surrounding andesite and dacite; ore occurs in the volcanic rocks. Zonneveld and Cohen (1952, p. 153) mention that vegetation differences permit photographic differentiation of the clay savannahs and sand savannahs of Surinam, South America. Bauxite production at Surinam's Billeton mine (Hemphill, oral communication, 1958) is from a clay area, and hence it is important to know the distribution of such clay areas.

INTERPRETATION OF AERIAL PHOTOGRAPHS IN ENGINEERING GEOLOGY

Aerial photographs have been used for many years to provide topographic and land-use information in locating routes for pipelines, highways, or other rights-of-way, but only in recent years have photographs attained wide recognition as a source of geologic information for engineering purposes. Many kinds of geologic information for engineering use may be obtained from aerial photographs. These include (a) identification and location of soil materials, particularly granular materials, which would provide suitable foundation sites for industrial and airport developments, or highway rights-of-way; (b) identification and location of clay and clayey silt soils, which would have detrimental properties with regard to building, airport, and highway sites; (c) location of aggregate materials; (d) delineation of areas that may be underlain by permafrost; (e) interpretation of distressed conditions in landslide areas; (f) analysis of structural geology in areas of tunnel, dam, and reservoir sites; and (g) location of sample areas for detailed investigation of soil and rock materials.

SURFICIAL MATERIALS

Surficial materials generally are interpreted in terms of gross physical characteristics, rather than the detailed physical characteristics used by the pedologist. Knowledge of the gross physical properties is sufficient for many reconnaissance studies in engineering geology. Indeed, it is the grouping of several pedologic soil types into a few classifications that permits aerial photographs to be of significant engineering use. In the preparation of soil-engineering maps from agricultural reports of an area in Illinois, Thornburn (1951, p. 91) was able to reclassify 99 different pedologic soil types into 13 engineering groups. Lueder (1951) described the use of aerial photographs as a major tool in preparing soil-engineering maps.

The inability to interpret fine details with regard to physical characteristics of the soil thus does not preclude the use of aerial photographs in many engineering geology studies. From the standpoint of engineering significance a granular material, for example, which exhibits certain diagnostic photographic characteristics such as coarse-textured drainage, will generally react favorably to drainage, compactability, and other engineering tests, regardless of whether it is a residual granular material that has resulted primarily from weathering in place or whether it is a transported gravel derived from different rock types. However, Jenkins, Belcher, Greeg, and Woods (1946) pointed out exceptions to the general thought that photographic characteristics common to granular materials always signify suitable granular materials for engineering purposes. For example, the soil profile of well-drained limestone has a granular texture due to aggregation of clay particles into lumps. The surface drainage may be coarse textured; but the soils break down on compaction and react as plastic soil material, and not as a granular material (Jenkins, Belcher, Greeg, and Woods, 1946, p. 80).

Where pedologic data are already available they may be very useful to the engineer when interpreted in terms of engineering test data (fig. 4). Indeed, certain soil mechanics tests by the engineer, such as plasticity or soil-texture tests, are similar to those used by the pedologist. Greenman (1951) suggested that the pedologic method can become the nucleus around which aerial photo interpretive and field geologic information can be accumulated. But Eardley (1943, p. 567) pointed out that "In many places conditions unfavorable for the development of a normal soil, such as rugged mountains, wide sandy plains, or swampy basins may cover rather large areas. The important construction materials in such places may be better interpreted as a result of geological processes than from the standpoint of a soil classification * * *."

GROUND CONDITIONS

The interpretation of ground conditions probably has received more attention in recent years than any other engineering geology application of aerial photographs. Much of the literature concerns reconnaissance studies of soils in general and granular materials in particular; granular materials are essential for building sites and highway and airport development (Jenkins, Belcher, Greeg, and Woods, 1946; and Purdue University, 1953). Special attention also has been given to photointerpretation of permafrost conditions in northern latitudes.

With regard to highway engineering, Belcher (1945, p. 144) stated that "* * * the soil problem resolves itself into two parts, one in which the soil in place is satisfactory as subgrade, and the second, where the soil is unsuitable. In areas of unsuitable soils some form

of improvement, by stabilization or insulation, is required. Insulation involves the economic location of granular materials in the form of rock to be crushed, cinders (volcanic), or sand and gravel * * *. Inasmuch as sand and gravel or other granular deposits exist to some extent in nearly every county in the country the significance of soil patterns indicating granular materials is of considerable economic importance to engineers." In fact, a large percentage of construction and maintenance expenses are in the costs of sand, gravel, crushed rock, and similar materials. As a tool for interpreting areas of gravel, sand, silt, and clay, aerial photographs offer an inexpensive and rapid method of reconnaissance, and according to Schultz and Cleaves (1955, p. 370) "* * * planning and exploration for large engineering projects should almost never be undertaken without a thorough study of aerial photographs of the region * * *."

Photointerpretation of surficial materials must consider not only the surface expressions of these materials but also the geologic factors reflecting the origin of these materials. A knowledge of the origin of materials permits inferences as to what kind of materials can be expected in an area, and in what locations with respect to other geologic features. Field-sampling programs also could be based on the analysis of the photogeologic data, and subsequent mineralogic and related studies by the engineering geologist could provide the soils engineer with information that would eliminate the need for many of the soil mechanics tests now performed as part of the routine laboratory analysis of all soil samples.

ELEMENTS OF SOIL PATTERN

The surface expressions of granular and other soils materials have been termed collectively the "soil pattern." The soil pattern consists of several elements of which the most important ones for nonpermafrost areas are considered to be landform, drainage, erosion, relative photographic tone, and color; vegetation cover and land use may also be significant (Belcher, 1944, 1945, 1948; Jenkins, Belcher, Greeg, and Woods, 1946; Frost, 1946; Mollard, 1947; Hittle, 1949; and Purdue University, 1953). Schultz and Cleaves (1955, p. 371) considered that "interpretation of soils by means of aerial photographs rests largely on the interrelationships of soils and geomorphic features"; consequently landform is considered by some to be the most important element in photointerpretation of soils. Landform, however, is only one element of the soil pattern and it is clearly evident that the association of several elements of the soil pattern will provide the greatest amount of information from aerial photographs.

Landform

Identifying the landform commonly identifies the natural process that formed it, and commonly limits the type of soils or soil characteristics that can be expected. The emphasis on landform is probably valid in reconnaissance soils investigations where broad areas of several different landforms are studied and mapping is at a small scale. But where detailed engineering information is needed, as in foundation studies, it is likely that the area of study will be within one landform, mapping will be on a large scale, and other elements of the soil pattern, such as differences in relative photographic tone, which may reflect soil-moisture content, will be of prime importance.

In small-scale mapping the emphasis on landform is probably warranted particularly for constructional landforms of transported materials, such as sand dunes, river terraces, alluvial fans, and many glacial landforms, all of which have distinctive shapes, although not necessarily unique (see figs. 52, 55–57, and 104); here the transported soil materials make up the landform. In contrast residual soils associated with destructional landforms may be more difficult to interpret from aerial photographs, for here the parent rock makes up the landform, and the significance of soils rests in part on the subjective interpretation of rock types. However, the interpretation of other elements of the soil pattern with regard to physical characteristics of soils are just as valid for residual as for transported materials; the engineering significance of many residual soil areas can be interpreted readily from aerial photographs on the basis of these other elements, such as drainage and erosional characteristics (figs. 63 and 65).

Drainage characteristics

Highly permeable soils will have good drainage regardless of their origin, provided that topographic positions will permit draining. In well-drained soils surface drainage normally will be coarse textured or even absent (figs. 49, 52, 66, 104, 106, and 108); in soils of low permeability drainage will normally be fine textured (fig. 63) or ponds may be numerous (figs. 57 and 66). The presence of fine- or coarse-textured drainage in surficial materials, like that in bedrock (p. 16), is primarily related to the relative resistance of the different materials to erosion, and hence related to permeability and grain size. Coarse materials characteristically are resistant to erosion, are permeable, and have a coarse-textured drainage; fine materials commonly are less resistant to erosion, are impermeable, and have a fine-textured drainage. These relations are significant in the interpretation of engineering soils from aerial photographs because drain-

age texture can be readily observed. However, exceptions to these relations may exist, as with loess, which is commonly characterized on aerial photographs by a relatively fine-textured drainage (see figs. 105 and 106); yet, loess in its natural environment is generally considered well drained internally.

Flow or channel markings, for example on terraces, indicate that the material was deposited by running water and further suggest that the material may be granular. Frost (1946, p. 121) described flow markings in an area in the midwest as consisting of light and dark streaks usually parallel to the direction of flow. The light streaks are ridges of sand or fine gravel that are probably sand and gravel bars; the dark streaks are fine clay or organic material deposited in depressions that once contained standing bodies of water. Frost (1946, p. 121) stated that "The chief significance of such markings lies in the fact that they suggest stream deposition and in order to have stream deposition at such elevated positions and occurring on * * * a large scale, there must have been large volumes of swiftly flowing water. Since swiftly flowing water allows only coarse material to settle, the terrace must contain a large percentage of gravel." It may be debatable that channel markings always indicate swiftly flowing water, but where some doubt exists other elements of the soil pattern may reveal the character of the terrace material.

In broad areas of aggradation, such as the Mississippi embayment, drainage characteristics revealed by aerial photographs are significant to the engineering geologist, as different soil characteristics are associated with the several features of valley alluviation. For example, backswamp areas contain clay and silty clay of high organic content, whereas natural levees consist of silt, silty sand, and some silty clay (Fisk, 1944, p. 18, 20). The levees commonly "* * * provide linear patterns of higher ground supporting distinctive vegetation growths" (Tator, 1951, p. 717). Low areas may be swampy and also contain distinctive vegetation. Graveliferous deposits fill the old valleys and in turn are covered by various other deposits; sandbars contain permeable sand that grades downward into the gravel. The distribution of features of the flood-plain drainage may be significant in analyzing ground conditions and locating favorable engineering materials in highway, railroad, and airport development.

Erosional characteristics

Closely related to the drainage characteristics of a soil are its erosional characteristics; these are important in photointerpretation studies chiefly from the standpoint of gully erosion, which is controlled largely by the physical properties of the soil and especially by cohesion. The usefulness of gully erosion characteristics in photointerpretation primarily involves the shape of transverse profiles, although longitudinal profiles may provide additional information. According to research workers at Purdue University (1953, p. 15–16) "* * * there are three basic gully characteristics which are associated with three major soil textural groups." Granular soils commonly develop sharp, V-shaped gullies that have short, steep gradients. Nongranular cohesive and plastic soils are generally indicated by uniform gentle gradient of gullies that extend well back into the upland, and by broadly rounded shallow V-shaped transverse profiles. The loess soils and sandy-clay soil exhibit U-shaped cross sections of gullies that have flat bottoms and low gradients.

Although there may be a general adherence of gully characteristics to the major soil textural groups, exceptions are not uncommon. For example combinations of the basic gully characteristics "* * * occur in 'layered soils' or in soils exhibiting a 'strong profile' ". (Purdue University, 1953, p. 16), and compound gradients may develop. In addition to the steep or vertical slopes in deep gullies, windblown silt may develop silt pinnacles and catsteps or terracettes (Purdue University, 1953, p. 45). It has been pointed out (Purdue University, 1953, p. 27) that climatic environment under which gullies form is an important consideration; for example, soft clay shale in an arid region where flash floods may occur commonly exhibit abnormally steep slopes in contrast to clay shale in areas of uniform rainfall where such slopes are usually softly rounded. Under certain conditions, such as gravel capping on clay soils in the New Jersey coastal plain (fig. 108), gullies in the underlying clay soils may be steep and deeply incised, in contrast to the usual broad shallow transverse gully profile of the clay soil group in humid regions.

In permafrost areas different materials may yield the same cross-sectional profile. Gravel deposits cemented by ice may have vertical gully walls, or may have gullies that are asymmetric in cross section if one side is preferentially exposed to the sun and thaws at a faster rate than the shadow side. The insulating materials overlying frozen deposits also affect the rate of thawing and hence the erosional characteristics of gullies. Interpreted carefully, however, the erosional characteristics—gully cross section and gradient—may reveal useful information on texture and other engineering characteristics of the soil.

Photographic tone

On black-and-white photographs the significance of color must be interpreted in terms of relative gray photographic tones. Belcher stated (1948, p. 486) that

"Light color tones (grays) are usually associated with well-drained soils, while clays, principally because of their water-retention capacity, appear dark." Frost (1946, p. 122), in describing the mottled soils in Indiana, stated that mottling nearly always indicates gravel. The mottling is due to "dark areas" which are "* * * small clay-like pockets that have been formed by the normal weathering processes of the gravel-sized material" (Frost, 1946, p. 122). These pockets are depressions that "* * * act as small infiltration basins which result in a higher moisture content and a darker color pattern" (Frost, 1946, p. 122). This mottled soil pattern contrasts with that of the drift plains in other areas where light-toned patches of slightly higher and dryer silty soils adjoin lower areas of wet plastic silty clays. Somewhat similar mottled patterns have been described by Gwynne (1942, p. 202–205) from the drift plain in Iowa (see fig. 107). But light photographic tones also may result from lack of moisture, owing to lack of precipitation as in many arid regions, rather than because of good drainage, and thus tone may be of little significance in evaluating soil texture in some areas. Or light tones may be the result of topographic position, and it is probable for example that a "* * * sand dune on a sand plain in a humid region will photograph light in color against a dark background" (Purdue University, 1953, p. 26) not because of differences in soil textures but because of topographic position. Climatic conditions also influence the colors of soils, especially the residual soils, and dark color rather than light color may be associated with well-drained materials, as certain red soils developed from limestone (Jenkins, Belcher, Greeg, and Woods, 1946, p. 84). Yet, provided climatic conditions are considered and provided relative photographic tone is borne in mind, the generalization that light photographic tones suggest good drainage and dark tones poor drainage may be useful in the overall interpretation of soils with regard to moisture content. Where tone is due to moisture, infrared photography will result in strong tonal contrasts between soils of different moisture content.

Color

Color has been cited as a principal element of the soil pattern that may yield information on the texture and drainage character of the soil profile, but to date very little interpretive work has been done with color photography. Belcher (1945, p. 138) briefly mentioned experimental color photography taken in different parts of the United States and stated that "The value of color * * * lies in the added detail that it furnishes with respect to these two elements of the soil pattern" (that is, soil color and details of vegetative cover). It would seem that color photography would reveal pedologic information significant in engineering evaluation of soils, especially the residual soils, which may be more difficult to interpret in general than transported soils, particularly from black-and-white photographs.

Vegetation

Vegetation as an element of the soil pattern has been considered one of the most difficult to interpret. It is known, for example, that certain trees, such as aspen, are tolerant of many different soils and soil conditions, but some types of vegetation are strongly influenced by soil type. Furthermore, vegetation may be influenced significantly by climatic factors. Where permafrost is close enough to the surface to affect tree and shrub roots the kind of vegetation that will grow may be restricted (see p. 37). Species identification may be difficult in any area unless large-scale photographs are available or unless pure stands are present. Nevertheless, vegetation may reveal significant information in engineering studies provided valid interpretations are made with regard to how vegetation is associated with soil textures, soil-moisture content, and topography; thus a knowledge of plant ecology is necessary if maximum information on soil conditions is to be obtained from aerial photographs. Willows, for example, indicate wet ground, poplar indicates dry ground, and jack pine implies sand and gravel beds (Belcher, 1945, p. 139). However, where abrupt changes in soil conditions exist, it is likely that vegetation changes will also occur (figs. 56 and 72), and areas needing further ground surveys may be easily delineated by inspection of aerial photographs without any basic knowledge of plant ecology. For example, stabilized sand dunes in interior Alaska can be easily delineated because they are marked by stands of dark-toned spruce (see fig. 56), in contrast to light-toned brush and grass of the interdune areas. This relation may be found where the topographically higher, well-drained sand of the dunes contrasts with frozen silty deposits of the interdune areas.

Where phreatophytes—plants and trees that obtain water from the water table—can be delineated (see p. 40), aerial photographs may provide significant engineering data because phreatophytes may choke overflow channels and thus increase the flood potential of some areas. Information pertaining to the downstream de-silting effect of phreatophytes with regard to dams and reservoirs may also be obtained from aerial photographs of some areas (see Robinson, 1958, p. 28–29). However, little interpretative work in this field has been done.

Land use

Land use may also reveal information on the soil conditions of an area. Belcher (1945, p. 142) reported that "Orchards thrive in well-drained locations and therefore, when observed on level ground, good subdrainage is implied." Shallow drainage ditches in areas of little relief commonly signify plastic, poorly drained soils. Schultz and Cleaves (1955, p. 378) stated that in eastern France and western Germany "* * * rugged topography and associated sandy soils developed on sandstones are generally left in forest; the comparatively level topography and associated clayey soils developed on shales and limestones are cultivated * * *." On the flood plain of the Mississippi River the silty sand of the natural levees is cultivated primarily because of its topographic position above the lower backswamps. In parts of the Valley and Ridge province of Eastern United States the limestone areas commonly are farmed whereas shale areas may be left in forest.

PERMAFROST

Permafrost has a significant effect on engineering characteristics of soils of the far northern latitudes and has received considerable attention in recent years, particularly from the standpoint of photointerpretation (Cabot, 1947; Woods, Hittle, and Frost, 1948; Benninghoff, 1950; Frost and Mintzer, 1950; Frost, 1951; Sager, 1951; Black, 1952; Hopkins, Karlstrom, and others, 1955). Considerable disagreement exists, however, on the significance of photointerpreted data in the study of permafrost areas (see Black, 1952, p. 126–127, 129), although it is generally agreed that aerial photographs can be particularly useful in such studies. The following discussion of ground conditions in permafrost areas is taken from the work of Hopkins and Karlstrom (Hopkins, Karlstrom, and others, 1955), except as noted by specific references.

Muller (1947, p. 219) defined permafrost as "a thickness of soil or other surficial deposit or even bedrock, at a variable depth beneath the surface of the earth in which a temperature below freezing has existed continuously for a long time (from two to tens of thousands of years)." Muller (1947, p. 30) also stated that "From the standpoint of engineering, the content of ice in frozen ground is of paramount importance * * * [because] * * * thawing of this ice produces excessive wetting and undesired plasticity of the ground and renders it unstable and susceptible to settling, caving, and even flowing." Building foundations, highways, railbeds, and airport runways may be considerably damaged unless the presence of permafrost is taken into consideration and measures taken to eliminate or minimize the effect of the thawing that results from the disturbance of the natural thermal regimen. Where bedrock or thick frozen gravel deposits that contain local drainage channels are the primary foundation materials, permafrost is not normally detrimental to construction.

Although aerial photographs are useful in the interpretation of areas that may be underlain by permafrost, criteria used for interpreting soil conditions of nonfrozen areas apply only to a limited extent to permafrost zones. Gully characteristics of an impermeable gravel deposit cemented by ice, for example, will not necessarily be the same as the characteristics of gullies in impermeable nonfrozen soils. Because of the altered permeability and porosity of soils owing to permafrost, erosional characteristics, as applied to the interpretation of nonpermafrost areas, may have little significance in the perenially frozen regions. Other criteria, such as the common landforms, although suggestive of type of material present, are of limited use in determining the presence or absence of permafrost. Few diagnostic indicators of permafrost appear to exist. More often than not the criteria are suggestive rather than indicative; they include distribution and type of vegetation, polygonal relief patterns, pingos, and features resulting primarily from thawing.

Distribution and type of vegetation

Distribution patterns of trees and shrubs commonly supplement topographic expression in recognizing landforms; these patterns may contribute indirectly to the interpretation of probable permafrost conditions based upon inferences concerning the age of the land surface, climate, and character of the underlying material. In addition, the type of vegetation may be useful in delineating areas where permafrost is likely to be present. Hopkins and Karlstrom (1955) reported that recognition of shallow-rooted species on aerial photographs aids in delineating the areas where permafrost is most likely to occur at shallow depth, and that recognition of deep-rooted species helps delineate areas least favorable for the formation or preservation of permafrost. Thus, black spruce may suggest areas underlain by permafrost at shallow depth, whereas tall willow shrubs and isolated pure stands of balsam popular on river flood plains generally indicate unfrozen ground. The distribution patterns of trees and shrubs, however, are most significant only when evaluated together with other information, such as type of landform, concerning permafrost distribution in the region under study.

Polygonal relief patterns

Polygonal relief patterns commonly can be identified on aerial photographs, but as they may be present

in both permafrost and nonpermafrost areas this criterion is not, by itself, always diagnostic in evaluating permafrost conditions; however, in conjunction with other features it may be very significant. Polygonal patterns may be divided into two broad groups: those formed by frost-stirring and those formed by contraction. The formation of frost-stirred polygons is favored by the presence of permafrost at shallow depth, but these polygons are not necessarily an infallible indicator of shallow permafrost as they are also known to occur where permafrost is absent or is at a considerable depth.

Contractional polygons are subdivided into low-center, high-center, and frost-crack polygons. Low-center polygons, one of the most dependable indicators of permafrost, are commonly found in poorly drained depressions. The presence of pools of water in the centers of some polygons is a diagnostic recognition feature, and it is common to find low-center polygons expressed on aerial photographs as dark-toned centers surrounded by light-toned marginal ridges (figs. 109–112). High-center polygons occur in slightly better drained areas than those in which low-center polygons are found; generally, the centers are relatively level, although they may be domed where frost is extremely active. In contrast to low-center polygons, drainage around high-center polygons is commonly concentrated in marginal trenches, and pools of water are present at trench intersections. Because of the high centers, these polygons are commonly expressed on aerial photographs as light-toned centers surrounded by dark-toned margins (figs. 40 and 109–112). Frost-crack polygons may be difficult to distinguish on aerial photographs, as they are similar to high-center polygons; they may be present in some areas where permafrost is absent.

Other relief patterns in conjunction with vegetation distribution result in striped slopes that are commonly present in permafrost areas (fig. 40).

Pingos

Pingos are rounded or elliptical steep-sided hills formed by the "downward freezing of a body or lens of water or of semi-fluid mud" (Muller, 1947, p. 59). They may be as much as 300 feet high. Fissures may develop along the axis of a pingo or radiate from the crest. Pingos usually are found in poorly drained areas and normally are readily distinguished on aerial photographs by their distinctive local landform (figs. 110 and 111); they are almost always a reliable indicator of permafrost, although locally they may be confused with erosional knolls or hills.

Features resulting from thawing

Two features associated with thawing are suggestive of the presence of permafrost. These are thaw lakes (sometimes called thermokarst lakes) and beaded drainage. Thaw lakes occur in frozen fine-grained sedimentary deposits that generally contain clear lenses and masses of ice whose volume is greatly in excess of the porosity of the unfrozen material. As this ice melts the ground subsides and forms a basin in which a thaw lake may accumulate (figs. 110 and 111). When caving is progressing, banks are ragged and steep or overhanging. Tilted trees known as "drunken forests," along the margins of such lakes are indicative of active caving. In treeless areas active caving may be indicated by tension cracks parallel to the banks. Other indications of thawing, such as serrated margins of lakes, also may be present (figs. 109–111). The usefulness of thaw lakes as permafrost indicators, however, is limited by the difficulty of distinguishing on aerial photographs between active thaw lakes, relict thaw lakes, and similar-appearing lakes that are in no way related to permafrost.

Beaded drainage occurs particularly in perennially frozen peat and silt containing ice wedges; it is characterized by small pools connected by short watercourses that may be sharply incised (figs. 40 and 112). The pool banks commonly are steep as a result of thawing and caving of frozen materials.

Absence of permafrost

In areas of discontinuous permafrost it is not only desirable for the engineer to know where permafrost is present, but it may be equally important to determine where permafrost is absent. Certain hydrologic phenomena and elements of the soil pattern commonly indicate or suggest the absence of permafrost. For example, subterranean drainage in unfrozen zones within permafrost may be detected on aerial photographs of some areas. The recognition criteria are in part similar to those applied in evaluating soil conditions in nonpermafrost areas of the world. That is, streams may disappear into the bottoms of closed depressions or by percolating into a gravel-covered surface. In addition, the presence of dry depressions in permafrost areas may indicate locally well-drained areas, inasmuch as there is generally a source of water during the summer months. Such areas contrast with other areas of the earth's surface where dry depressions may be due to absence of precipitation or other immediate source of water. Locally unfrozen zones within permafrost areas may also be suggested by springs, which are commonly indicated by flood-plain icings, shown as flat, white surfaces on some aerial

photographs, or indicated by more luxuriant vegetation along a pronounced lineation or within a dark-toned area on low hill slopes. These unfrozen zones may be favorable as a source of ground water. In addition, because permafrost generally causes soils to be impermeable, drainage characteristics indicative of permeable materials (see p. 34) may be interpreted to mean lack of permafrost, at least in the immediately underlying materials. Certain tree species may also suggest absence of permafrost (see p. 37).

EROSION, TRANSPORTATION, AND DEPOSITION

LANDSLIDES

Natural movement or potential movement of materials is a significant consideration in many construction engineering problems. Foremost in this regard is the movement of soils and rock materials by landslides. Ritchie (1958, p. 67) stated that "All landslide investigations must start with recognition of a distressed condition in the natural or artificial slope * * *." Distressed conditions are commonly interpretable from aerial photographs. "The evidence for distressed conditions that may be present, or that may be induced, lies chiefly in evidence of movements, minor or major, that have already taken place or of geologic, soil, and hydrologic conditions that are likely to cause movement in the future" (Ritchie, 1958, p. 67). Geologic, soil, and hydrologic conditions signifying potential landslide areas include the presence of unfavorable geologic structures and rock type, prevalence of fine-grained materials, and an abundance of water or conditions that would permit access of water to fine-grained materials.

Because remedial measures for landslides or prevention of landslides are generally not only difficult but costly, avoidance of landslide areas is important in highway route layout. Existing landslides are commonly identified on the basis of landform (figs. 46 and 113). Liang and Belcher (1958, p. 70) stated that some landforms are more susceptible to landsliding than others, and thus identifying the landform is highly important. "Potential slides of the rockfall and soilfall type can commonly be foreseen simply by recognizing geologic conditions that are likely to produce overhanging or oversteepened cliffs" (Ritchie, 1958, p. 51). Basalt cappings underlain by easily eroded shale (figs. 53, 87, and 113) illustrate a condition where rockfalls may occur as a result of failure and slump in the underlying materials.

Movement of unconsolidated materials by flowage is likely to produce the most damaging landslides. Existing flows and slides (figs. 46 and 113) commonly have a "hummocky" surface. Landslide scars, where soils and vegetation have been stripped off the bedrock, may be easily recognized on aerial photographs by the light photographic tone of the bedrock in contrast to darker tones of surrounding areas. Areas of potential flow of unconsolidated materials may be revealed by tension cracks or crevices, or suggested by the presence of seepage zones or springs, shown by dark tones of dense or luxuriant vegetation or by dark tones of the soil.

Ritchie (1958, p. 50) warned, however, that although aerial photographs are of significant help in developing the setting for detailed studies, they seldom contain the detail needed by the engineer to carry out preventative or remedial measures. The prime application of aerial photographs in landslide studies appears to be in interpreting ground conditions to determine areas that should be avoided in highway route layout and similar problems.

BEACH EROSION

In a shoreline study in California, Munk and Traylor (1947) showed that variation in wave height and refraction of waves along the shore was controlled in part by sea-floor topography. Where refraction causes a convergence of waves the rate of shoreline erosion may increase. Krumbein stated (1950, p. 203) that "Refraction diagrams are becoming an essential part of any study concerned with shore processes, and graphic methods have been developed for preparing them from hydrographic charts or aerial photographs." Photographs taken periodically of shoreline areas would also provide information, both qualitative and quantitative, in studies of erosion and deposition, which might thus be useful in planning remedial action against the eroding currents. In a study of shoreline erosion by the U.S. Army Corps of Engineers (U.S. Beach Erosion Board 1946, p. 13) aerial photographs taken in 1941 were compared with land surveys of 1836 to obtain rates of erosion along the shore of Lake Michigan. The rate of erosion plays a significant part in planning corrective measures for eroding currents.

BEDROCK

GEOLOGIC STRUCTURE AND TYPE OF ROCK

Because of the influence that faults may have on construction design and costs, it is important that faults be located and studied in the beginning stages of an engineering project. Aerial photographs may provide significant information in this regard as some faults are recognized from subtle expressions on photographs but are identified only with difficulty on the ground. The usefulness of photographs in mapping a proposed damsite in southeastern Alaska is shown in a

study of the Swan Lake area (fig. 114) where faults stand out in aerial view as conspicuous lineations, which are primarily reflections of rectilinear depressions on the ground. In a damsite study in Malaya, Alexander and Proctor (1955) used large-scale aerial photographs taken 750 feet above the ground. These photographs showed clearly the attitude and distribution of faults and joints in granitic country rock. In connection with the San Jacinto tunnel project in California, Henderson (1939) noted that aerial photographs revealed indications of unsuspected faults and corroborative evidence of those previously suspected. Fault locations underground were found to be close to that predicted from study of photographs.

In addition to showing faults, aerial photographs commonly shown dipping beds that are important in some foundation studies for pier and abutment location. Or dipping beds may indicate potential rockslide conditions where the dip is in the same direction as the hill slope.

Lithologic characteristics of bedrock materials are also significant in many engineering problems, as in foundation work, or in locating road metal sources. Criteria useful for interpreting the general lithologic character of rock types from aerial photographs are discussed on pages 16–19.

INTERPRETATION OF AERIAL PHOTOGRAPHS IN HYDROLOGIC STUDIES

LOCATING POTENTIAL GROUND-WATER SOURCES

Little has been written on the interpretation and uses of aerial photographs specifically in hydrologic studies, although photogeologic techniques offer both practical and research applications in this field. Practical application of aerial photographs in hydrologic study are at present confined largely to assisting the geologic mapping in ground-water investigations, particularly in areas covered by surficial materials. As an aid in ground-water mapping, elements of the soil pattern are evaluated in terms of ground conditions, just as in many engineering geology studies (see p. 34–37). Thus, for example, coarse-textured drainage or absence of drainage may signify highly permeable materials (figs. 52, 66, 88, 104, and 105*B*; and p. 34–35) or the landform (figs. 52 and 104) may suggest the kinds of materials that compose it, which permits an evaluation of permeability and porosity and potential as a water reservoir. In addition, aerial photographs may reveal information directly suggesting the presence of water, such as a preferential distribution of vegetation at the margins of a gravel cap (see figs. 104 and 108). The type of vegetation in turn may permit inferences with regard to the general quality of water. For example, salt cedar is tolerant of relatively high content of salt in water, whereas cottonwood trees are intolerant. Howe (1958) described briefly the use of aerial photographs with specific reference to locating possible water-bearing formations.

WATER-LOSS STUDIES

In a study of water loss caused by phreatophytic plants and trees, which take their water from the water table, Turner and Skibitzke (1952) used aerial mosaics and contact prints for delineating areas of different densities of phreatophytes. The areas were then measured by planimeter and used in conjunction with vertical foliage density, determined by field methods, to arrive at volume density to which water loss by transpiration for specific species could be equated. Data pertaining to tree species and heights were determined by ground methods. Turner and Skibitzke (1952, p. 67) stated that "The comparison between results obtained by air and by ground mapping led to the conclusion that the former offers a much faster and more accurate method, particularly in areas of dense growth." Further use of aerial photographs in collecting basic data for studies of water loss by phreatophytes could probably be made. For example, it may be possible to determine tree or plant species, especially when large-scale black-and-white photographs are available or where color photographs have been taken. In addition, for many areas where the ground surface can be observed through the trees, photogrammetric measurements may provide rapidly those height measurements needed in water-loss studies. For areal measurements of differing vegetation types or densities a simple dot-templet method may be useful (Wilson, 1949). Like many other studies, however, where vegetation and ground features must be observed, measured, and plotted, maximum use of aerial photographs will result from combined use of field and photogeologic methods.

OTHER APPLICATIONS

Aerial photographs as a tool in hydrologic studies provide a medium for obtaining basic data, such as cross-section profiles, linear, areal, slope, and volume measurements. Some of the suggested uses of photogrammetric techniques in hydrologic studies are: (a) for definition of channel size and shape of cross section to be used in studies of the effect of channel geometry in flood characteristics of streams; (b) for determining channel storage capacity used in flood-frequency correlations; (c) for definition of the three-dimensional sinuosity of natural channels to be used in studies of the rate of energy loss; (d) for definition of the geometry of bed roughness of alluvial channel

models (Thompson, 1958); (e) for measuring topographic characteristics of drainage basins such as stream slopes and drainage density; and (f) for determining areas of lakes and swamps in water-storage studies.

INSTRUMENTATION

Instruments in photogeologic study serve three objectives, namely, interpretation, measurement, and plotting of data. The instruments used thus may be photogrammetric or nonphotogrammetric—photogrammetry is the art of making reliable measurements from photographs. Usually different instruments are used for attaining each of the three objectives, as, for example, in using a stereoscope, parallax bar, and radial planimetric plotter, respectively. But all three operations may be combined in a single piece of equipment, such as the Kelsh plotter (fig. 18). Whether interpretation is done with a simple stereoscope and paper prints or with a precision stereoplotting instrument using glass-plate diapositives, the criteria of recognition, described in the first part of this paper, remain the same except insofar as scale and resolution of photographic details are involved. Both measurement and plotting are here considered as mechanical aids that provide quantitative information to be further used in geologic interpretation of an area, and instruments are discussed primarily with this objective in mind.

Measurement involves (a) the determination from aerial photographs of vertical and horizontal distances, which in turn are used to compute stratigraphic thicknesses, angles of dip, and other quantitative data of geologic use; (b) the direct determination of inclined distances, commonly the stratigraphic thickness of a formation; (c) the direct determination of angles of slopes or beds; and (d) other quantitative determinations of possible significance in geologic interpretation, such as light-transmission measurements.

Plotting primarily involves the orthographic positioning of geologic data from aerial photographs to base maps or compilation sheets. It also involves direct plotting of geologic data in cross-sectional views, and may include positioning data such as geologic contacts, which are not directly recognizable in the stereoscopic model, by use of the floating dot or spatial reference mark that is found in many photogrammetric instruments.

KINDS OF INSTRUMENTS

Many different photogrammetric instruments are available for making measurements and plotting geologic data to base sheets or cross-sectional profiles (see Fischer, 1955; Ray, 1956; Pillmore, 1957; and Hemphill, 1958a). Certain instruments permit only the measurement of altitude differences, others permit only the orthographic positioning of geologic data, but many instruments are used for both measuring and plotting. Most measuring and plotting devices are designed to accommodate standard 9- by 9-inch photographs; enlarged photographs can be used with only a few instruments, such as the overhead projector, in transferring data to a base sheet.

MEASURING DEVICES FOR USE WITH PAPER PRINTS

One of the most commonly used and widely available types of instrument for determining altitudes from paper prints of aerial photographs is the stereometer or parallax bar. Several varieties of stereometers are available for use with either the lens or mirror-type stereoscope (see fig. 10); they consist of two small plates, usually of glass or plastic, that have inscribed dots, or other targets, that can be centered over conjugate image points in a stereoscopic pair of photographs. The plates are attached to a supporting bar along which they may be separated horizontally. The supporting bar generally has graduated readings in millimeters or inches and a slow-motion adjustment drum that permits readings of hundredths of millimeters or thousandths of inches. All stereometers are based on the "floating-dot" principle, where two target dots, one seen with each eye, are fused stereoscopically into a single dot that appears to float in space within the stereoscopic model. The apparent height of the single fused dot, used as a reference mark in determining altitude differences, is related to the horizontal separation of the individual dots being viewed. Thus by measuring the horizontal separation between individual dots when the fused dot in the stereoscopic model is placed at the top of an object (such as a hill or cliff) whose height is to be determined, and subtracting from it the measurement of the horizontal separation between individual dots when the fused dot is placed at the bottom of that object, a measure of the height, called differential parallax, is obtained. Differential parallax is converted to feet by simple mathematical calculations (see p. 53). Stereometers are thus merely devices that permit reliable measurement of differences of horizontal distances between two or more pairs of conjugate image points as seen on two photographs that form a stereoscopic pair.

Parallax ladders also may be used for determining differences in altitudes from aerial photographs. Like the stereometer, the parallax ladder is based on the floating-dot or floating-line principle. The instrument may consist of two diverging rows of dots on plastic or glass arms; thus, a series of pairs of dots exist with

different horizontal separations, and this in turn results in several floating dots all at different altitudes within the stereoscopic model (see fig. 12). Or the instrument may consist of two diverging lines with intercepts of specific horizontal separations ticked off; thus a single plunging line would be seen in stereoscopic view. The instrument, oriented at right angles to the flight line, is used by sliding it over the stereoscopic model until a pair of dots or line intercepts—seen stereoscopically as a single dot or cross in space—appears to fall on the base of the object whose height is to be determined. A reading of the horizontal separation of the two dots or intercepts is then made. The parallax ladder is moved until a different pair of dots or intercepts—also seen stereoscopically as a single dot or cross in space—appears to fall on the top of the object whose height is to be determined. Again a reading of the horizontal separation of dots or intercepts is made. The difference in readings obtained is then used in a simple formula to determine the difference in altitude of the two points (see p. 53). A direct-reading parallax ladder that eliminates the need for most of the mathematical computation has also been devised. The differences in horizontal separation of pairs of dots has been calculated by the manufacturer in terms of heights in feet for different flying heights and photobases, and this permits a direct reading of relative altitudes within the stereoscopic model.

Also for use with paper prints is a stereo slope meter, designed primarily for determining degrees or percentage of slope. The instrument consists of two transparent disks each scribed with eccentric circles of specific diameters (fig. 11). These disks are mounted in a frame so as to be movable horizontally in a fashion similar to the dots of the stereometer. In stereoscopic view the two sets of eccentric circles appear as a cone that is divided into several zones. By proper horizontal spacing of the two disks, the resulting cone seen stereoscopically can be raised or lowered so that some two circles will rest on the slope or grade to be determined. By appropriate simple calculations the slope can be determined. Center dots present on each of the transparent disks also permit relative altitudes to be determined just as with a stereometer.

PLOTTING DEVICES FOR USE WITH PAPER PRINTS

Instruments have been designed specifically for plotting information from paper prints to base maps or control sheets. An instrument widely employed in the past is the sketchmaster (fig. 13), which uses the camera-lucida principle in transferring data from the photographs to the base sheet. The sketchmaster allows the operator to view a single photograph image superposed on the base map. Adjustments for scale changes in the perspective photograph permit coincidence or near coincidence of photograph control points and base-map control points. Geologic detail is sketched directly on the base map. This instrument can be adjusted to remove small amounts of tilt inherent in some vertical photographs, but like any direct-reflecting projector, large amounts of radial displacement due to relief cannot be effectively removed.

The radial planimetric plotter has been devised especially for transferring photographic detail to a base map or control sheet. Unlike the sketchmaker, this instrument is designed to eliminate displacement due to relief. The plotter consists of a mirror stereoscope mounted above two photograph tables (fig. 14). A transparent plastic arm with a centrally scribed line extends from and pivots around the center of each table. These arms are linked to a pantograph attachment. Because the plastic arms radiate from different centers they cross each other in stereoscopic view to form the so-called plotting cross.

In operating the radial planimetric plotter a pair of vertical photographs is oriented on the photograph tables for proper stereoscopic viewing, and control points on the photographs are oriented to control points on the base manuscript by means of the radial arms and pantograph. Movement of the pantograph attachment moves the plotting cross over the stereoscopic model and permits tracing of photograph detail on the base manuscript. Inasmuch as the radial arms that intersect a terrain feature on each photograph represent azimuth lines from known points on the base manuscript, the intersection of these two arms will represent the true map position of that feature, just as will the intersection of two azimuth lines shot from different instrument stations in the field. Thus the relief displacement of a feature on a photograph is effectively removed; this is one of the chief advantages in using the radial planimetric plotter. However, the radial lines do not intersect along the principal line—or flight-line direction—between photographs, and the photograph tables must be shifted to their alternate centers before the central area of stereoscopic model can be delineated. Because the photograph tables are mounted in a horizontal position, the instrument does not permit removal of tilt that may be present in the photographs, but tilt is usually small in present-day photography and generally does not cause significant errors in horizontal positioning of geologic data.

The multiscope is a combination of mirror stereoscope and camera lucida that has received limited use

COMBINED MEASURING AND PLOTTING INSTRUMENT FOR USE WITH PAPER PRINTS

in plotting geologic data from photographs to base maps or control sheets. Photographs are mounted on movable photograph plates that permit small adjustments for tilt. The viewing assembly is constructed to allow the insertion of one or two half-silvered mirrors in the eyepiece, so that in operation either the image of a single photograph or the stereoscopic model may be superposed optically on the map or control base. Although the stereoscopic model may be seen at all times, use of only one half-silvered mirror permits the eye to see only the image of one photograph superposed on the map base; the resulting plot is similar to that from the sketchmaster—or reflecting projector—no errors due to relief displacement are removed. If, however, two half-silvered mirrors are used, appropriate manipulations permit true orthographic plotting of detail from the stereoscopic model. Scale adjustments between photographs and map base are made by interchanging special lenses in the viewing assembly together with changing manually the distance of the viewing assembly above the map base. The instrument is said to permit measurement of altitudes when coupled rotary prisms are inserted under the half-silvered mirrors, or when a device similar to the multiplex tracing table is placed in the field of stereoscopic view (Spurr and Brown, 1945, p. 177).

MEASURING AND PLOTTING DEVICES FOR USE WITH PAPER PRINTS

Some instruments have been designed both for measuring altitudes and for plotting data from paper prints of aerial photographs. These instruments are commonly termed "paper-print plotters" and include the KEK plotter, the Mahan plotter, and the stereotope.

The KEK plotter consists of a stereoscope, two photograph tables, floating-dot assembly, and drawing attachment. The plotting cross of the radial planimetric plotter is replaced in the KEK plotter by the fused dot floating in space. By raising or lowering the photograph plates the fused dot is positioned on the ground in the stereoscopic model. Vertical motion of the photograph plates is linked to a drum scale on which relative altitudes can be read directly in feet. Movement of the pantograph drawing attachment allows geologic detail to be sketched directly on the map base, but during this sketching the fused dot must be held on the ground in the stereoscopic model by simultaneous vertical movement of the photograph plates. The photograph plates may be tilted to make an approximate correction for tilt that may be inherent in the photography. Because the floating-dot assembly lies above and is physically separated from the photograph tables, small amounts of extraneous parallax and significant amounts of horizontal shift in the map position of a point may result by moving one's head in viewing the stereoscopic model.

The Mahan plotter is generally similar in principle to the KEK plotter but differs slightly in operation. The floating dot is positioned on the ground in the stereoscopic model by vertical motion of the disks on which the dots are scribed, whereas in the KEK plotter the position of the disks containing the scribed dots is fixed and the photograph plates are moved vertically in order to position the floating dot at a particular level in the stereoscopic model. The stereoscope of the Mahan plotter is adjustable, which permits very nearly the recovery of the perspective from photography ranging in focal length from about 8.25 to 12 inches. As with the KEK plotter, a shift of the viewer's head when viewing the model may cause horizontal positioning errors and the presence of small amounts of extraneous parallax. The stereoscopic model of the KEK and Mahan plotters may be effectively leveled, in absence of vertical control, by visual reference to certain physiographic features of the terrain (see p. 55).

A somewhat different paper-print plotter is the stereotope. The instrument consists of a stereoscope with binoculars of × 4 magnification mounted over a photoholding assembly that contains a parallax bar and attachments for pantograph hookup, as well as a mechanism, when vertical control is available, for effectively leveling tilted models, for correcting errors of horizontal position, and for orthographic plotting of geologic data (fig. 15). The stereotope is an elaborate instrument that corrects for tilt by mechanical linkages within the photoholding assembly. No physical tilting of the photoholders takes place and thus the instrument differs significantly from the KEK and Mahan plotters. In addition, the targets of the stereometer attachment for altitude determinations are in contact with the paper prints, and no extraneous parallax can be introduced by movement of the operator's viewing position. In the absence of vertical control, which permits tilt correction through mechanical linkages, the stereotope as a measuring device must be used as a simple parallax bar.

MEASURING AND PLOTTING DEVICES FOR USE WITH GLASS-PLATE DIAPOSITIVES

The Kelsh plotter, multiplex, and ER–55 plotter, all of which require glass-plate diapositives, are used in the United States both to measure quantitative geologic data and to plot geologic detail to base maps or control sheets (figs. 16–18). These double-projection precision-plotting instruments are designed to accom-

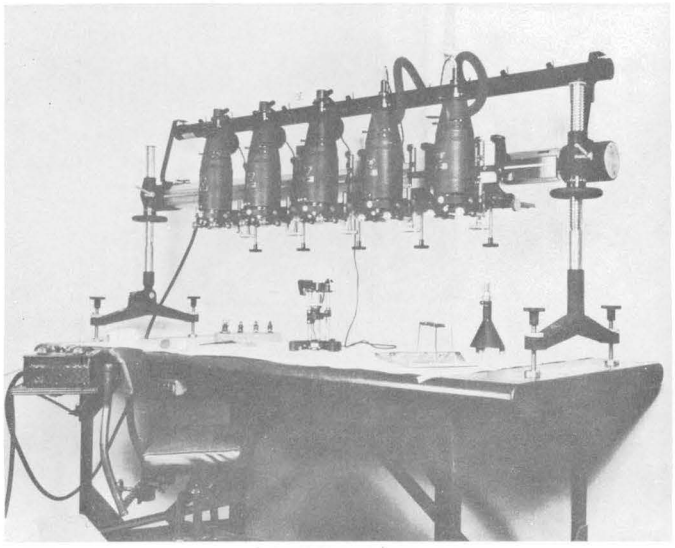

FIGURE 16.—Multiplex.

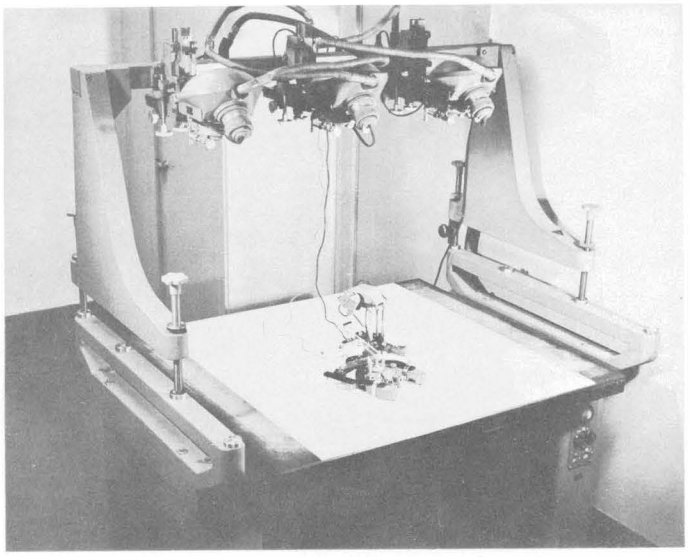

FIGURE 17.—ER–55 plotter.

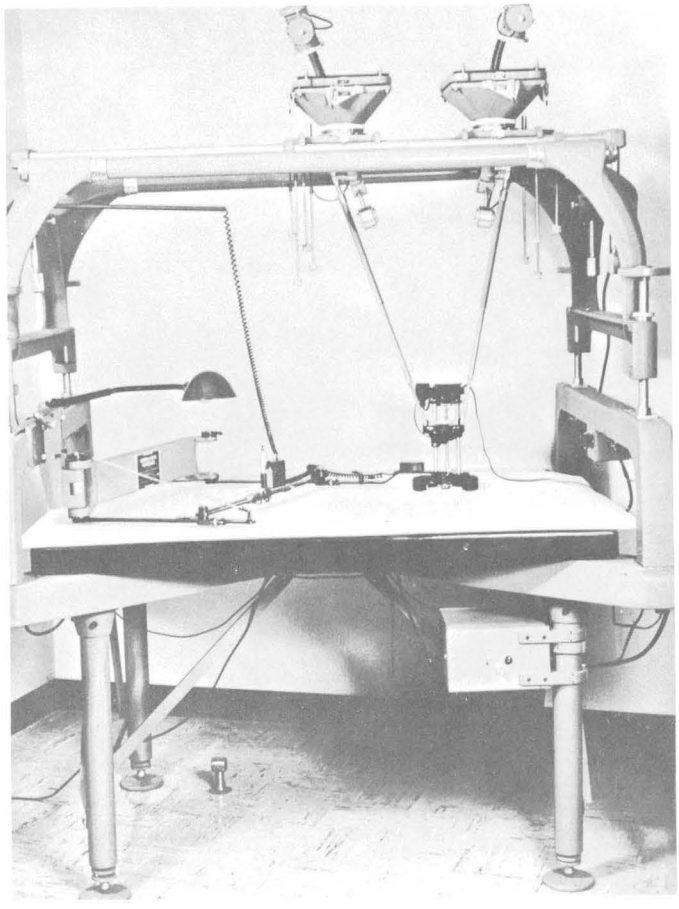

FIGURE 18.—Kelsh plotter.

COMBINED MEASURING AND PLOTTING INSTRUMENTS FOR USE WITH GLASS-PLATE DIAPOSITIVES

modate photography of specific focal lengths, usually 6 or 8.25 inches. All utilize the anaglyph principle of projection of light of complementary colors, red and blue-green, through glass-plate diapositives to create the third dimension. The stereoscopic model is viewed through glasses of the same color as the filters used in the light-source projectors. Because double-projection, or anaglyphic-type, stereoplotting instruments simulate in miniature the spatial relations of the camera stations at the time the photographs were taken, all features of the terrain are optically re-created in the stereoscopic model in essentially true relation with respect to the measuring mark or floating dot. Where sufficient vertical control is available any tilt inherent in the photography can be removed so that accurate measurements of altitudes can be made and true orthographic positioning of detail obtained. Without vertical control the stereoscopic model of many terrains commonly can be leveled within 1° of the horizontal datum by visual reference to certain physiographic characteristics of the terrain (see p. 55); under these conditions approximate orthographic positioning may be obtained, but significant errors in vertical measurements may result (see p. 69–75).

The stereoscopic model is usually viewed on a small white-surfaced table called a platen, which may be raised and lowered so that an illuminated floating dot in its center is kept in contact with the surface of the ground, as seen in stereoscopic view. Vertical motion of the platen is transmitted to a scale reading in millimeters of vertical measurement, or, on some instruments, to a scale that converts readings directly to heights in meters or feet. Geologic features are traced orthographically on the base map by a pencil located directly beneath the illuminated dot on the platen, or by a reduction pantograph attached to the tracing table. Interpretation, measuring, and plotting can be carried out in one continuous operation.

The Kelsh plotter is designed to accommodate glass-plate diapositives the same scale as the original photography. For many geologic problems film positives may be substituted for the more expensive glass-plate diapositives. The scale of the projected stereoscopic model is usually about 5 times that of the original photography. Only that part of the stereoscopic model appearing on the platen is illuminated; this results in a concentration of light and a brightly illuminated model but prevents viewing of the entire model at one time. Because the glass-plate diapositives are the same scale as the original photography the resolution of the stereoscopic image is excellent.

The multiplex uses glass-plate diapositives on which the original 9- by 9-inch negative is reduced about 5 times. The small diapositive image is then enlarged approximately 12 times in projection of the stereoscopic model. The projected stereoscopic model is about 2.5 times the original photography scale. As a result of the large amount of reduction of the original photograph negative, some of the photographic detail is lost and fine details of terrain, important in geologic interpretation, may not be visible. In multiplex projection the entire model area is illuminated, and if the terrain being viewed has only low or moderate relief the stereoscopic model may be observed in its entirety by substituting a large white surface for the platen. This overall view of the stereoscopic model is often of considerable use in geologic interpretation, because of the association of geologic features that can be seen at one time. The overall view is generally accomplished by projecting the stereoscopic model to the multiplex table slate; no plotting or measuring can be done when the model is viewed on this surface.

The ER–55 plotter uses glass-plate diapositives on which the original 9- by 9-inch negative is reduced about 2.8 times; this amount of reduction does not seriously affect image resolution. The projected stereoscopic model is about 3.5 or 5 times the scale of the original photographs, depending on the projector model. Ellipsoidal reflector-type projectors result in a brightly illuminated model in which terrain detail has a high degree of resolution. Like the multiplex, the ER–55 plotter permits viewing the entire stereoscopic model at one time. In addition to accommodating vertical photography the ER–55 projectors are adaptable to twin low-oblique photography taken with the camera axis inclined 20° from the vertical position.

Geologic study of stereoscopic models in double-projection plotters has numerous advantages over the study of paper prints. The ability to interpret, measure, and plot in one continuous operation has already been cited. In addition, the geologist works with an enlarged stereoscopic model that ranges from about 2.5 times to 5 times the original photography scale, depending on the instrument used; thus small-scale photography commonly may be used. A higher degree of image resolution is maintained on glass diapositives than on paper prints, and results in more detail that can be observed in the double-projection stereoscopic models, except for the multiplex, in which some resolution needed in qualitative and quantitative interpretation is lost in the projected model. Because all features of the terrain are optically re-created in essentially true relation, reliable measurements for structure contouring, for drawing isopach lines, for computing strikes and dips, and for determining fault displacements can be obtained for many areas with stereo-

scopic plotters; measurements can be made rapidly and hence economically (see Pillmore, 1957).

OTHER INSTRUMENTS

Other photogrammetric instruments such as the stereoplanigraph and autograph permit precise measurements from aerial photographs, but these heavy plotters are generally unavailable to the geologist. Beside permitting precision of measurement, these instruments are designed to accommodate different sizes of diapositives and photography taken with different focal-length lenses.

Certain modifications or additions to existing instruments have been made specifically for geologic purposes; and some new instruments, described below, have been designed expressly for geologic study.

EXAGGERATED-PROFILE PLOTTER

The exaggerated-profile plotter is a device attached to the tracing table of double-projection plotters, such as the Kelsh, multiplex, and ER–55 plotters, for drawing terrain profiles. As the tracing table is moved along the line of profile and as the platen of the tracing table is moved vertically a pencil attachment records the profile on a vertical tracing board. Profiles exaggerated as much as 5 times may be plotted. An arm on the tracing table slides in a groove along the base of the tracing board so that a selected cross-section direction is maintained. Two models of the exaggerated-profile plotter have been developed. One is based on the lever and fulcrum principle (fig. 19); the other is based on the pantograph principle (fig. 20). The exaggerated-profile plotter was first developed to aid in solving a specific geologic problem in correlating thin and closely spaced intraformational sandstone beds in rocks of Cretaceous and Jurassic age in Wyoming (Pillmore, C. L., oral communication, 1958). The plotter may be very useful also in quantitative geomorphic studies or in studies involving the qualitative correlation of shape characteristics of terrain.

INTERVAL-MEASURING DEVICE

A floating-dot instrument that permits the maintenance of a desired vertical interval between two floating dots in a stereoscopic model from paper prints, as well as serving as a conventional stereometer, also has been developed in the course of photogeologic study (Hackman, R. J., oral communication, 1959). Two floating dots, representing different altitudes in the stereoscopic model, may be useful for example in positioning an obscured formation contact when other contacts are readily observed and formation thicknesses are known. The instrument consists of two transparent circular disks mounted on a frame with two worm screws, one of which permits separation of the disks in the x direction, and the other of which permits both disks to be rotated equally but in opposite directions (see fig. 21). A series of dots, evenly spaced, are arranged in a straight line so as to pass through the center of each disk. One dot coincides with the center of each disk and can be moved only in the x direction, as in most stereometer-type instruments. The other dots may also be moved in the plane of the disk by rotating the disk, thus providing a parallax ladder as seen stereoscopically. By proper adjustment a pair of dots, one on each disk, can be separated by rotation of the disks to provide a direct-reading parallax ladder, or the dot separation may be referred to millimeters of parallax and differences in altitude calculated in the usual manner (see p. 53). The center dots of each disk can be floated in the stereoscopic model at a desired point and the distance above or below this point measured merely by rotation of the disks. Scales graduated to record hundredths of millimeters of parallax permit readings of separation of the center dots of the disks as well as reading of total x parallax resulting from rotation or x motion of the disks.

UNIVERSAL TRACING TABLE

Some research in development of instruments carried out to date has centered around the modification of existing instruments. Important in this group is the universal tracing table (fig. 22), which is a multiplex tracing table that has been modified in design by R. H. Morris and C. L. Pillmore of the Geologic Survey. It is used for direct measurement of inclined distances, such as stratigraphic thickness of dipping beds, in stereoscopic models from double-projection plotters. The platen and underlying assembly can be tilted as much as 45°. A separate worm-screw drive on the tilted assembly distinct from the conventional worm-screw drive for vertical movement, permits movement of the platen in an inclined direction perpendicular to the surface of the platen. A scale on this auxilliary worm-screw-drive assembly permits the reading of measured intervals in hundredths of millimeters; conversion to feet is made in the usual manner for double-projection stereoscopic models (see p. 54–55). A series of holes drilled through the platen to the underlying light source provides a plane of floating dots in the stereoscopic model.

MEASUREMENT

PRINCIPLES OF VERTICAL MEASUREMENT

Vertical measurements of altitude differences provide by far the greatest amount of quantitative information in geologic interpretation from aerial photographs. Differences of altitudes are generally deter-

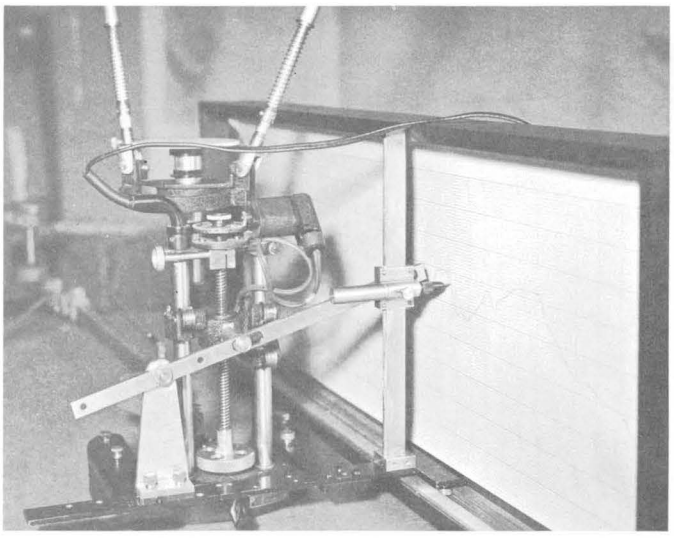

FIGURE 19.—Lever and fulcrum type of exaggerated-profile plotter.

INSTRUMENTS DESIGNED OR MODIFIED FOR GEOLOGIC USE

mined from overlapping aerial photographs, although they may under special circumstances be determined from a single photograph. When overlapping prints are used, the altitude difference between any two points is determined by measuring the horizontal linear parallax difference between the two points and relating it to appropriate geometry of the stereoscopic model. Altitude determinations from glass plates in double-projection plotters require the measurement of actual vertical distances within the stereoscopic model. In the uncommon circumstance when a single photograph may be used, altitudes are determined by measuring relief displacement and relating it to appropriate geometry of the aerial photograph.

DETERMINATION OF ALTITUDE DIFFERENCES BY THE PARALLAX METHOD

When an object is viewed or photographed from two different positions, as on two overlapping vertical aerial photographs, an apparent shift in the position of that object takes place, which is known as parallactic displacement. On overlapping aerial photographs this is a measurable linear distance that is directly related to the height of the object. In photogrammetric terms parallax of an image point appearing on two overlapping photographs is called absolute stereoscopic parallax and is represented by the algebraic difference, parallel to the flight line, of the distances of the conjugate image points from their respective principal points (see fig. 23). The difference in absolute stereoscopic parallaxes between two different image points is a measure of the distance one point is above the other. On overlapping paper prints the parallax difference may be measured reliably by using a stereometer-type instrument, based on the floating-dot principle; parallax difference may also be measured with a ruler, although this procedure is rarely used because of inaccuracy of measurement.

In double-projection stereoplotting instruments (Kelsh, multiplex, and ER–55 plotters) an actual vertical measurement of altitude difference is made within

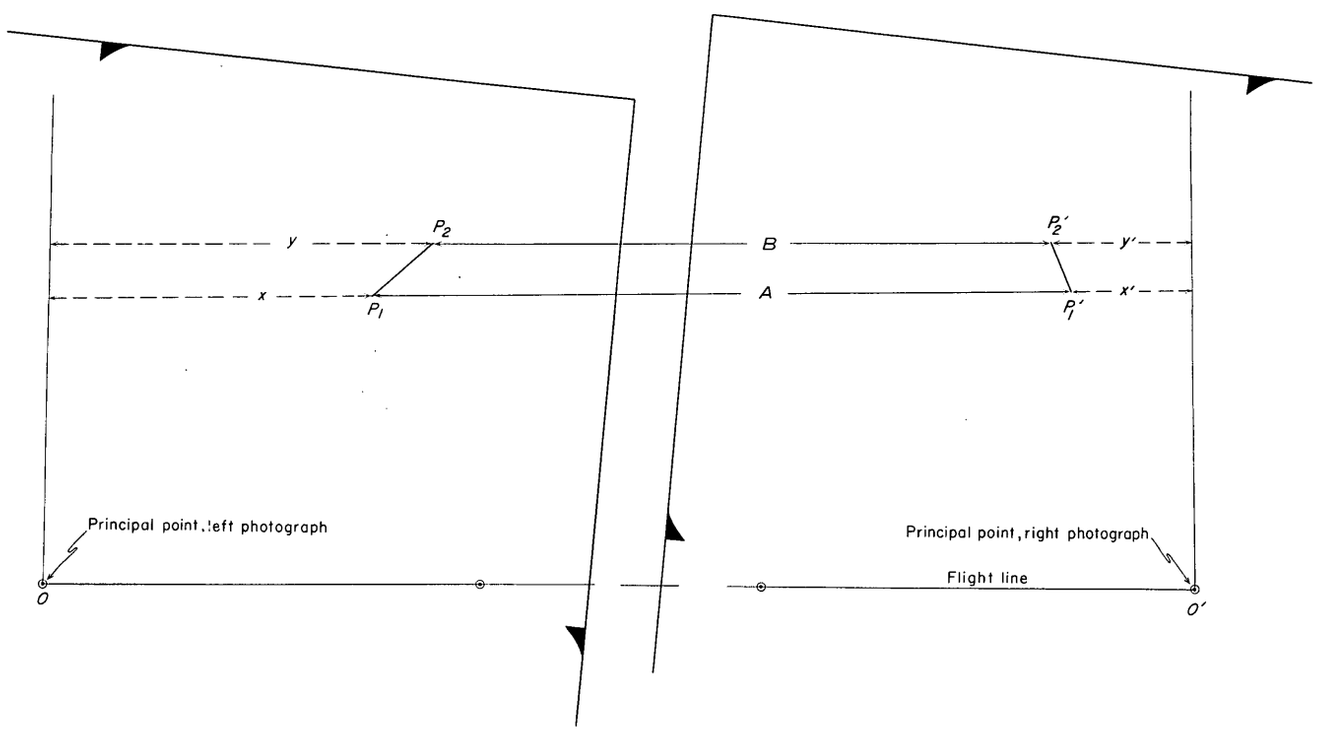

FIGURE 23.—Diagram showing relation between absolute stereoscopic parallaxes and horizontal distances actually measured with stereometer-type instruments in determining differences in altitude from paper prints.

Let images P_1'–P_2' and P_1'–P_2' represent the photographic expression of a pole on the left and right photographs of a stereoscopic pair. The absolute stereoscopic parallax of the base of the pole is $x-(-x')=(x+x')$. The absolute stereoscopic parallax of the top of the pole is $y-(-y')=(y+y')$. (Distances measured to the right of the principal point are positive, to the left, negative). The parallax difference between the top and bottom of the pole then is $(y+y')-(x+x')$.

From the figure:

$$y+y'+B=x+x'+A$$
$$y+y'-x-x'=A-B$$
$$(y+y')-(x+x')=A-B.$$

Thus the difference in absolute stereoscopic parallaxes is equal to $A-B$. The distances A and B are the actual distances measured with stereometer-type instruments, generally in hundredths of millimeters, in determining altitude differences from paper prints.

the stereoscopic model; the linear parallax recorded on the photograph is translated into a vertical distance as a result of angular parallax in the viewing arrangement. Figures 23 and 24 show diagrammatically the distances that are actually measured when stereometer-type instruments and double-projection instruments are used respectively in altitude determinations.

USE OF STEREOMETER-TYPE INSTRUMENTS

When paper prints of aerial photographs are used in conjunction with a stereometer-type instrument and a stereoscope, two linear horizontal distances must be measured to obtain the parallax difference between two different image points. These distances are simply A and B as shown on figure 23. They can be measured with a finely graduated ruler but more commonly a

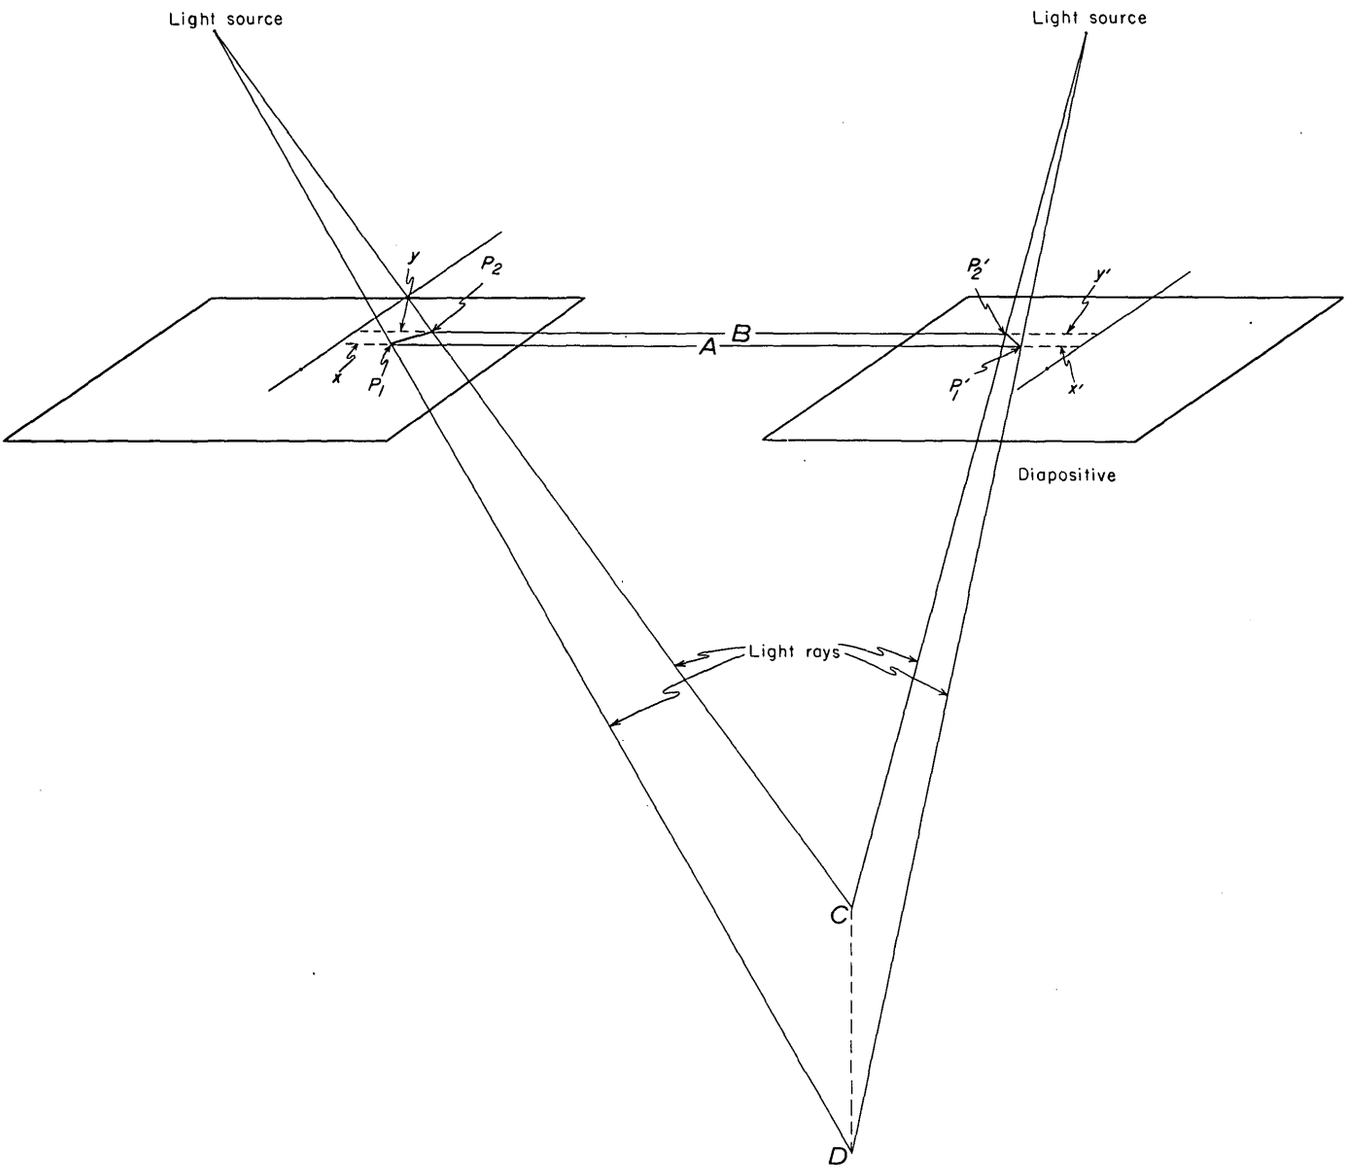

FIGURE 24.—Diagram showing relation between absolute stereoscopic parallaxes and vertical distance measured with double-projection type instruments in determining differences in altitude from glass plates.

The absolute stereoscopic parallaxes of the top and bottom of a pole represented on the left photograph by P_1–P_2 and on the right photograph by P_1'–P_2' are $(y + y')$ and $(x + x')$, as in figure 23, and differential parallax between the top and bottom of the pole is $(y + y') - (x + x')$ *or* $A - B$. With double-projection instruments the vertical distance CD is actually measured, rather than the horizontal distances that are measured on paper prints. The distance CD, measured generally in tenths of millimeters, is converted to feet by multiplying by the K factor, which represents the number of feet on the ground per 0.1 millimeter in the stereoscopic model. Points C and D represent the intersections of those light rays that pass through the top and bottom of the pole respectively.

stereometer-type instrument or parallax bar is used because it permits more consistent readings of smaller increments of length than a ruler. Stereometers are generally constructed with a principal scale graduated in millimeters and a subordinate drum scale calibrated in hundredths of millimeters for recording parallax measurements; a few instruments are designed to record in inches.

To make parallax measurements from aerial photographs it is first necessary to orient the photographs properly for stereoscopic viewing. This is accomplished by alining the photograph centers and conjugate centers along a straight line—the equivalent of the flight-line direction—and separating the photographs for comfortable viewing (fig. 25). Photograph centers are located by marking the intersections of lines drawn between fiducial marks at the opposite sides of each print. Each center is then transferred stereoscopically to the other photograph of the stereoscopic pair and its conjugate image point marked. Parallax measurements are then made in the so-called x direction, parallel to the flight line. Measurement is accomplished by adjusting the separation of the dots of the parallax bar until a single fused dot, seen stereoscopically, appears to rest on the ground at the first point selected. The instrument reading is recorded and the procedure is repeated for the second point selected. The difference in readings is the parallax difference between the two points. In making parallax measurements the fused dot will be seen readily when it floats above the apparent ground surface of the stereoscopic model but will appear to split into its two component dots as it is lowered below the ground surface. If the fused dot, as it is being lowered, appears to split at some point just above the ground surface, a slight change in the separation of the photographs may be necessary to permit simultaneous viewing of the floating dot and the stereoscopic model.

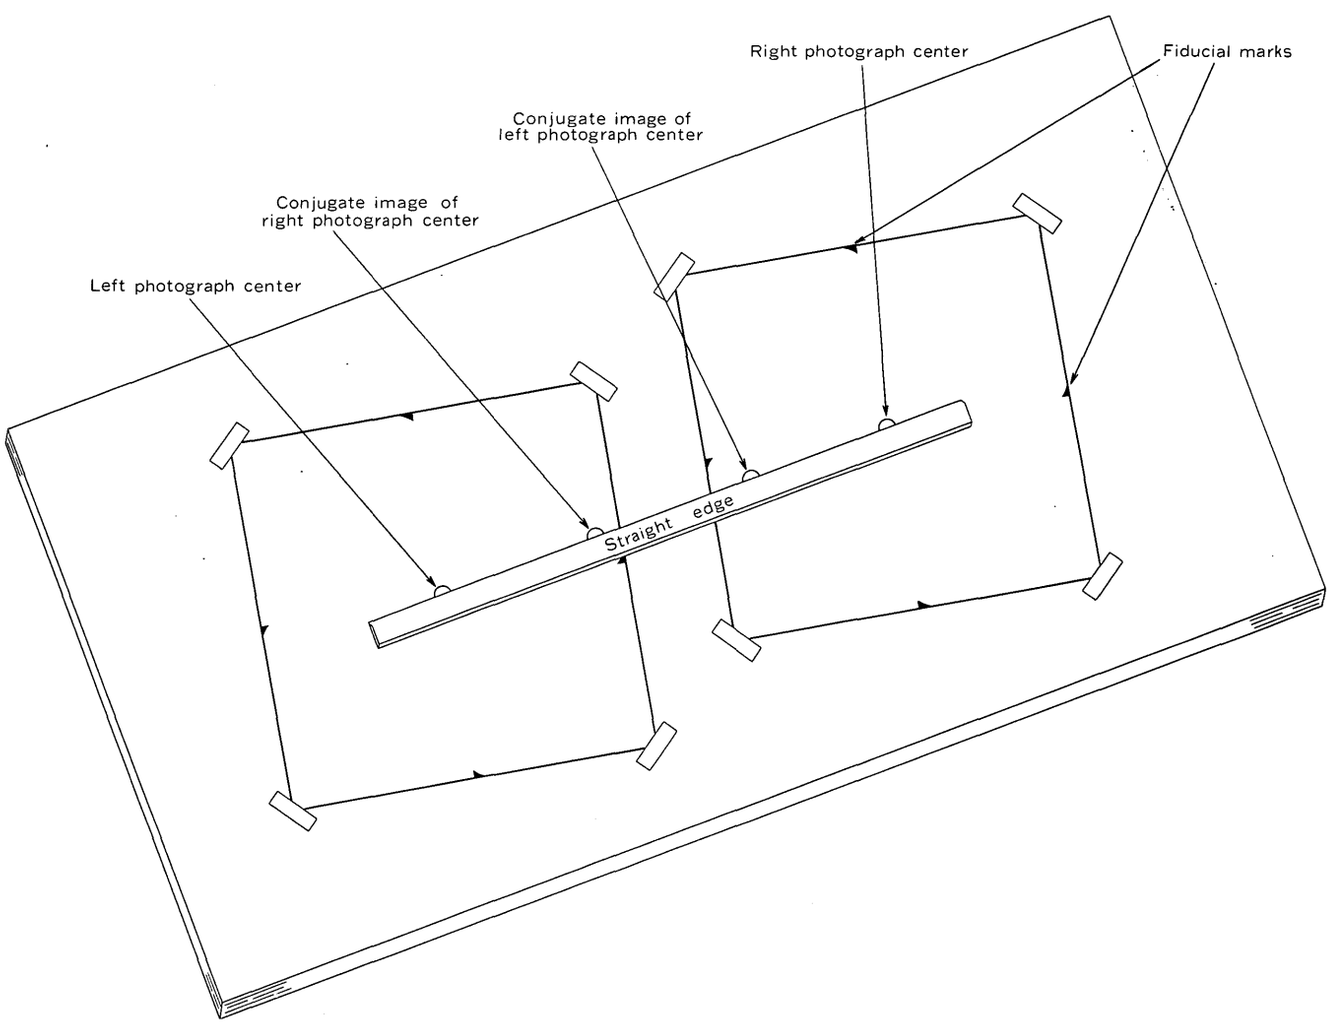

FIGURE 25.—Sketch showing correct orientation of photographs for stereoscopic viewing.

To obtain the height of an object or difference in altitude between two points the difference in parallax must be related to the geometry of the stereoscopic model. For measuring heights from paper prints this relation is best expressed by a formula which, in its simplest terms, is

$$h=\frac{H}{b}\cdot\Delta p \qquad (1)$$

where h=height of the object, in feet, or difference in altitude being determined;
H=height of airplane, in feet, above mean terrain (determined from specifications of photographic mission or relation $H=f/S$, see below);
b=photobase (commonly determined by averaging the distances between the center and conjugate center of each photograph of the stereoscopic pair); units of measure may be millimeters or inches but must be the same as Δp;
and Δp=parallax difference, in millimeters or inches, as determined with stereometer-type instrument (distance A–B of figure 23).

It will be noted that as H increases, the measure of Δp for any given vertical interval will decrease; however, the absolute value for any one unit of Δp will increase correspondingly. On the other hand, if focal length is increased and flying height remains constant the measure of Δp for a given vertical interval will increase but the absolute value for any one unit of Δp will decrease correspondingly.

The above formula (1) may be used without any appreciable error if relief in an area is low; Δp will be small. If relief in an area is high one of the following two formulas, (2) or (3), should be used:

$$h=\frac{H'}{ab+\Delta p}\cdot\Delta p \qquad (2)$$

where h=height of the object, in feet, or difference in altitude being determined;
H'=height of airplane, in feet, above the lower of the two points whose parallax difference has been measured;
ab=photobase adjusted to the lower of the two points whose parallax difference has been measured (commonly determined by measuring the distance between photograph centers—*0–0′* of fig. 23—and subtracting from it the distance between conjugate image points at the lower altitude—distance A of fig. 23); units of measure may be millimeters or inches but must be the same as Δp;
and Δp=parallax difference, in millimeters or inches, measured with stereometer-type instrument (distance A–B of figure 23);

or

$$h=\frac{H'}{ab-\Delta p}\cdot\Delta p \qquad (3)$$

where h=height of the object, in feet, or difference in in altitude being determined;
H'=height of airplane, in feet, above the upper of the two points whose parallax difference has been measured;
ab=photobase adjusted to the upper of the two points whose parallax difference has been measured (commonly determined by measuring the distance between photograph centers—*0–0′* of fig. 23—and subtracting from it the distance between conjugate image points at the upper altitude—distance B of fig. 23); units of measure may be millimeters or inches but must be the same as Δp;
and Δp=parallax difference, in millimeters or inches, measured with stereometer-type instrument (distance A–B of figure 23).

Formula (2) is used when H' and ab are determined by referring to the lower of the two points whose altitude difference is desired, as in measuring upward from the base to the top of a cliff. Formula (3) is used when H' and ab are referred to the upper point, as in measuring downward from the top to the bottom of a cliff. Most commonly the lower of two points is selected as the reference point and measurements are made from that point to some higher point in the stereoscopic model; thus formula (2) is more widely used than formula (3).

Parallax differences generally can be read within small tolerances (see p. 73), and errors in computing differences in altitude result mainly in the determination of flying height and photobase, assuming photographs have little or no tilt. It is therefore generally desirable to determine flying height (H') and adjusted photobase (ab) carefully because a given percentage error in one of them may cause a similar percentage error in the computation of altitude difference. In addition, failure to use formula (2) or (3) when parallax difference (Δp) is large will also cause a considerable error in the final result even though the adjusted photobase (ab) has been carefully determined.

For calculation of absolute heights as is necessary, for example, in determining stratigraphic thickness or displacement on faults, the factor H' may be determined from a base map of known scale or from other control using the relation $H'=f/S$. If the altitude difference between some two points, A and B, is desired

and if neither A nor B falls in a convenient map position for scaling a distance and determinnig H' for one of them, it may be necessary to make parallax measurements with respect to some selected third point, C, for which the flying height (H') can be readily calculated.

Where altitudes are to be used for computing angles of dip it is not necessary to know the absolute height of H'; the tangent relation of angles

$$\text{Tan angle of dip} = \frac{\text{vertical distance}}{\text{horizontal distance}} \qquad (4)$$

involves only relative horizontal distances and relative differences of altitudes, and thus any value may be assumed for H' when measuring parallax difference and determining the scale of the photograph to be used in computing dips. In photogrammetric terms this relation may be expressed as

$$\text{Tan angle of dip} = \frac{\text{flying height (feet)} \times \text{parallax difference}}{\text{horizontal distance on ground (feet)} \times \text{adjusted photobase}} \qquad (5)$$

$$\text{or Tan angle of dip} = \frac{H' \cdot \Delta p}{d \cdot (ab \pm \Delta p)}. \qquad (6)$$

Since

$$\frac{\text{flying height (feet)}}{\text{horizontal distance on ground (feet)}}$$

is also equal to

$$\frac{\text{focal length (inches)}}{\text{horozontal distance on photograph (inches)}}$$

the following formula may also be used to calculate angles of dip when flying height, H', is not known or cannot be determined:

$$\text{Tan angle of dip} = \frac{\text{focal length} \times \text{parallax difference}}{\text{horizontal distance on photograph} \times \text{adjusted photobase}}. \qquad (7)$$

The tangent of dip, in photogrammetric terms, has been described in more detail by Desjardins (1943b, p. 1536–1538) and Elliott (1952, p. 8). When angles of dip are determined from enlarged photographs and formula (7) is used, the effect of photographic enlargement on focal length must be considered; effective focal length is increased in direct proportion to the amount of photographic enlragement (see p. 4).

Hemphill (1958a, p. 43) has devised a chart that shows the number of feet represented by each millimeter of parallax change as H' and ($ab + \Delta p$) of formula (2) vary. The factor determined from the chart is then multiplied by Δp to arrive at h, in feet, provided formula (2) is used. A simple circular photogrammetric computer has also been designed that permits easy computation of the number of feet represented by each millimeter or hundredth millimeter of parallax as flying height and photobase vary. In addition, the computer allows multiplication of this factor by the parallax change to give altitude differences in feet. The number of feet represented by each hundredth millimeter of parallax measured on paper prints may also be determined from the ratio

$$\frac{\text{Flying height (feet)}}{\text{Photobase (millimeters)} \times 100}.$$

This relation is further discussed on page 73.

Need for correct orientation of photographs.—Misorientation of a stereopair of photographs can be considered from the standpoint of rotation around the center of one or both of the photographs. This rotation results in misalinement of the stereopair and flight line. Parallax differences are not then measured in the true x direction, or flight-line direction, but at a slight angle to it; an error in the adjusted photobase also results. The measurement of parallax difference is not normally significantly affected but the adjusted photobase on a stereopair misoriented by a few degrees, even though the human eyes can tolerate a certain amount of error and yet see a well-defined stereoscopic image, may be in error by as much as 5 to 10 percent. This will cause a similar error in differences in altitudes determined by the parallax method when paper prints are used.

USE OF DOUBLE-PROJECTION INSTRUMENTS

When double-projection instruments are used to determine altitude difference between two points, only one distance need be measured. This is a vertical distance within the stereoscopic model that results from the translation of linear parallax recorded on the glass-plate diapositives to angular parallax in the viewing arrangement (fig. 24). The vertical position of intersecting light rays to the lower point to be measured is determined by placing the floating dot on the apparent ground in the stereoscopic model and recording the instrument reading. The vertical position of the upper point is recorded in a similar manner. The difference in readings is a measure of the parallactic displacement and is related to the difference in altitude of the two points. With double-projection instruments measurements are normally made in increments of tenths of millimeters, although some instruments are so designed that selection of proper gear trains permits readings to be converted directly to heights in meters or feet.

In stereoscopic models formed in double-projection instruments the vertical scale remains constant with

respect to the horizontal scale and a simple multiplication factor—called the K factor—for relating increments of vertical measurement to absolute feet can be determined by converting the standard fractional scale (representative fraction) of the model to feet per unit of vertical measurement, that is, per 0.1 millimeter. This is most rapidly accomplished using the formula

$$K=\frac{\text{model scale denominator}}{3{,}048\ (\text{number of tenths of millimeters in 1 foot})}.$$

Thus a stereoscopic model with a scale of 1:4,000 would have a K factor of 4,000/3,048 or 1.31 feet per 0.1 millimeter of vertical measurement. Increments of vertical measurement are merely multiplied by the appropriate K factor to obtain differences in altitude in feet. A constant factor for converting increments of vertical measurement to feet is appropriate because the horizontal and vertical scales are equal and constant throughout the stereoscopic model, but when paper prints are used, the horizontal scale is not constant throughout the model and hence different multiplication factors must be determined for different levels in the model.

Because the horizontal and vertical scales in stereoscopic models from double-projection instruments are equal and constant throughout the model, inclined distances, such as stratigraphic thicknesses of dipping beds, may also be measured. A special device for measuring distances in inclined directions was developed by R. H. Morris and C. L. Pillmore of the Geological Survey; it consists of a multiplex tracing table modified so that the platen, platen socket, and light source can be tilted as a unit (fig. 22). An additional worm-screw drive, separate from the conventional worm-screw drive, allows the platen to move in an inclined direction perpendicular to the surface of the platen. The resulting measured distance within the model is converted to feet in the usual manner, and a measure of the inclined distance is obtained.

TILT

Tilt in present-day vertical photography is generally small—under good flying and photographic conditions 50 percent of the photographs taken for domestic mapping are reported to be tilted less than 1° and 90 percent tilted less than 2° (see Tewinkel, 1952, p. 319). But tilt may be significant in the photogrammetric calculation of many geologic measurements, and care must therefore be exercised in determining altitudes from parallax measurements. The significance of tilt on vertical measurements used in geologic interpretation depends in large part on the geologic problem. Where vertical measurements must be referred to a horizontal datum, as in structure contouring, tilt may cause significant errors, but where relative vertical measurements between pairs of points are desired, as in constructing isopach lines, tilt may have relatively little effect especially where points of any one pair are separated by only a small horizontal distance (see p. 73). If only simple streometers are available for parallax determinations it may be necessary to entirely discard some photograph prints unless (a) vertical control is available and the geologist carries out the tedious task of constructing a correction graph (Desjardins, 1950, p. 2304–2305; McNeil, 1952, p. 610–615; and Visser, 1954, p. 849–853), or (b) points of measurement are selected so that the effect of tilt will be minimized (Hemphill, 1958a, p. 46–47, 49). It is also possible to partially correct for tilt locally on planar orientations, such as the strike and dip of beds, by stereographic projection and appropriate rotations in stereographic constructions.

If photogrammetric instruments are available that allow photographs to be tilted, it is generally possible to eliminate any large amount of tilt (greater than 1°) by careful inspection of physiographic features of the stereoscopic model, thereby permitting reliable parallax measurements to be made even though vertical control is not available for leveling the model. For example, lakes or other standing bodies of water may appear tilted, or certain streams or stream meanders may appear to flow uphill (fig. 109). Tilt is also often detected by observing that headwater tributaries in subdued divide areas where gradients are very low appear to flow uphill. Adjustment of the instrument so that the lakes appear flat and streams have a normal gradient will minimize tilt, and parallax measurements can then be made.

For certain sensitive measurements, such as measurement of low stream gradients or measurements used to determine the strike of low-dipping beds, it is essential that vertical control for leveling models be available and that a precision plotting instrument, such as the Kelsh plotter, be used. Because a small amount of tilt may seriously affect the measure of stream gradient the economic advantage of photogrammetric techniques may be lost where the measure of gradients is the primary photogrammetric objective, inasmuch as a considerable amount of vertical control must be obtained by ground survey to level the stereoscopic models. However, for many geologic measurements, particularly where relative intervals are to be measured, ground control, although desirable, is not essential for making satisfactory parallax determinations, either from paper prints or glass-plate diapositives.

DETERMINATION OF ALTITUDE DIFFERENCES FROM A SINGLE PHOTOGRAPH

Under certain conditions altitude differences between two points may be determined by making appropriate measurements of radial displacement on a single photograph and substituting them in the formula

$$h=\frac{mH}{r}$$

where h=difference in altitude desired;
m=relief displacement of upper image point with respect to the lower image point;
H=height of airplane above lower image point;
and r=radial distance from principal point of photograph to lower image point.

The distance m and r must be measured in the same units. The height, h, will then be in terms of the units chosen for H.

This procedure is only applicable to vertical objects where the upper point is known to be directly above the lower point. Under these restricted conditions, the length of the image of an object, such as a tree, or a cliff face at right angles to a radial line from the principal point, is a measure of the relief displacement. The radial distance to the lower point can be easily measured, and the flying height can be obtained from the formula $H=f/S$ (see p. 53–54) when base maps are available, or from the specifications of the photographic mission. Thus, for example, if the radial displacement of a cliff is 0.03 inch, the flying height of the airplane 10,000 feet, and the lower point is 3 inches from the photograph center, the height of the cliff will be

$$h=\frac{0.03\times 10{,}000}{3.0}$$

$$h=100 \text{ feet.}$$

Because relief displacement is generally small, a small error in measuring such a distance on a single photograph will result in a relatively large error in the height of the object, which further limits the usefulness of the formula for determining vertical intervals.

GEOLOGIC USES OF PARALLAX MEASUREMENTS

Parallax measurements always result in the determination of spot altitudes or vertical intervals when papers prints are used; and generally result in spot altitudes or vertical intervals when glass-plate diapositives are used in double-projection instruments, except when a special tracing table is used that permits measurement of inclined distances (fig. 22). These spot altitudes and differences in altitudes combined with horizontal distances determined from the stereoscopic model, or under some circumstances from a single photograph, may be used to compile structure-contour maps and to determine dips of beds, thicknesses of beds, offsets on faults, gradients of streams, and related data.

Because of relief displacement, however, it may be necessary to correctly locate the relative horizontal positions of points, whose altitudes have been measured, before computing strikes and dips, determining stratigraphic thicknesses, or any other geologic measurements where dips are involved. Because tilt is usually negligible in present-day photography, horizontal positions of points generally may be plotted satisfactorily with any instrument that removes relief displacement, such as the radial planimetric plotter, paper-print plotters, and double-projection plotters even though the stereoscopic model cannot be leveled. Horizontal distances may then be scaled off. However, in the absence of plotters for locating the relative map positions of radially displaced points when measurements are made with parallax bar and paper prints, an overlay or similar procedure may be used to determine corrected horizontal distances, unless orthophotographs (see page 69) are available from which correct horizontal distances may be scaled.

The overlay procedure requires first laying out on transparent material a line equal in length to the adjusted photobase. The overlay is then placed over the right photograph of the stereoscopic pair so that the line drawn is coincident with the flight direction and its right end terminates at the photograph center. Radial lines are then drawn on the overlay from the photograph center through all points whose relative horizontal positions are to be determined. The procedure is repeated with the overlay positioned over the left photograph, again with the original line coincident with the flight direction and its left end terminating at the photograph center. The intersection of a pair of lines through the same image points is the corrected horizontal position for that point.

DETERMINING STRIKES AND DIPS

Where bedding surfaces coincide with topographic surfaces it is generally sufficient to measure the altitude difference between only two points, one directly downdip from the other in calculating the amount of dip. The horizontal distance between these two points, together with the difference in altitude, gives the required information for determining the angle of dip from the trigonometric relation

$$\frac{\text{Vertical distance}}{\text{Horizontal distance}}=\text{tangent of angle dip.}$$

If relief in an area is low the horizontal distance may be scaled directly from a single photograph with-

out significant error in computing the dip, but where relief is moderate or high a correction for the relief displacement of the upper point with respect to the lower point generally should be made. In the unique circumstance where the strike is radial from a photograph center or where the surface on which the dip to be measured is at or near a photograph center, there is little or no relief displacement in the dip direction, and no correction in scaling the horizontal distance need be made. Hemphill (1958a, p. 53) suggested that the corrected horizontal distance between the upper and lower points should be at least 0.2 inch for computing dip angles. Where dips are greater than 50°, a longer horizontal distance is needed to determine the dip angle reliably, as the tangent increment per degree of dip is significantly greater for steep angles of dip than for low angles of dip.

The strike line generally can be determined readily by inspection of the stereoscopic model and noting two points of equal altitude on a bed. Where dips are low, however, tilt in the photographs will affect the direction of strike; the lower the dip, the greater the effect, generally, on the amount of shift in the azimuth of the strike line. Graphs may be constructed to show the effect of tilt on low-dipping beds. (See Hemphill, 1958a, p. 48.)

Where a bed crops out in a valley wall it will generally be necessary to determine the altitudes of three points on the bed. In areas of moderate or high relief corrections for relief displacement must be made before distances between these points can be determined; otherwise distances may be scaled directly from the single photograph. Determination of the strike direction and amount of dip are then made graphically or graphically and trigonometrically.

DETERMINING STRATIGRAPHIC THICKNESS

In areas where beds are horizontal or nearly horizontal the stratigraphic thickness may be determined directly by converting to feet the parallax difference between the top and the bottom of the bed. No correction is necessary for relief displacement. However, if beds are inclined, the angle of dip must first be determined; then corrections must be made for relief displacement and for the effect of dip on the stratigraphic thickness. The thickness may be calculated by simple trigonometry or by graphic solution (fig. 26).

Desjardins (1950, p. 2308–2309; 1951, p. 829–830) suggested that floating lines be employed with paper prints for determining stratigraphic thicknesses where beds do not dip more than 15°. In the "floating line" procedure, lines are drawn on transparent strips of

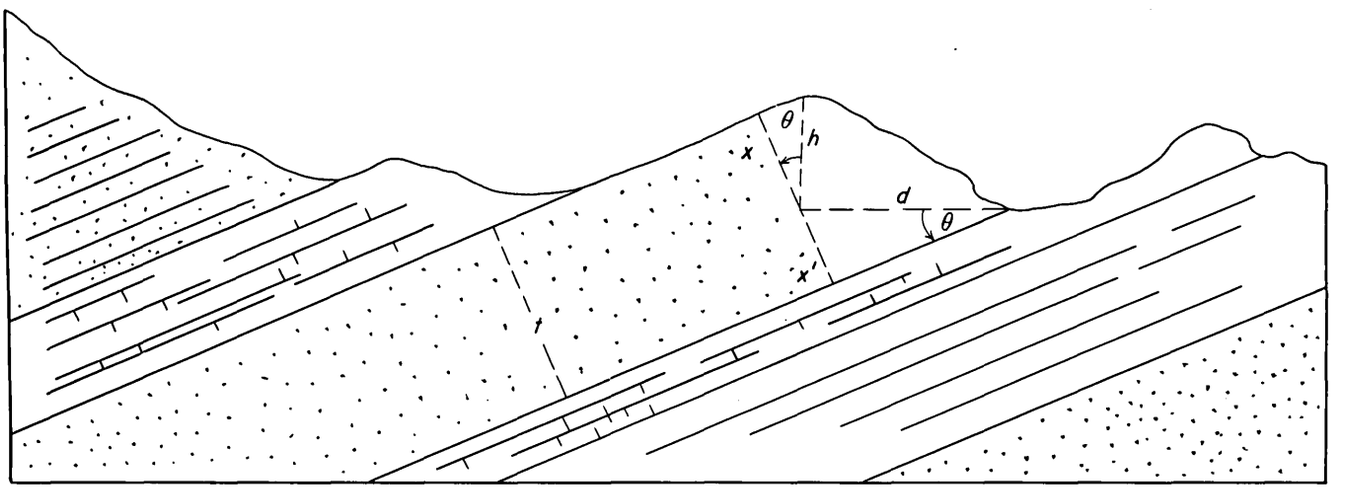

FIGURE 26.—Diagram of gently dipping beds showing relation of stratigraphic thickness to differential parallex determined at any two points along dip direction and at the formation contacts.

Stratigraphic thickness is determined from the formula

$$t = x + x' = \frac{h}{\cos\theta} + \frac{d}{\sin\theta}$$

where t = stratigraphic thickness;
h = difference in altitude between some point on the lower contact of the bed and some point, along a line at right angles to the strike line, at the upper contact of the bed; altitude h is determined from the parallax formula;
d = corrected horizontal distance between points at lower and upper contacts of the bed;
and θ = angle of dip.

material that are superposed over each of the photographs. When one line over one photograph is positioned parallel to a line over the second photograph, a single floating line will appear when viewed streoscopically unless the lines are parallel to the flight direction. The line will float above or within the model and appear to be horizontal; its vertical position in the model will depend on the separation of the two individual lines in the flight direction. A series of lines will form a grid or reference plane (Smith, H. T. U., 1943a, p. 171; Desjardins, 1943a, p. 219; Hackman, 1957, p. 593). When any one pair of lines is divergent rather than parallel the floating line in the stereoscopic model will appear to plunge. By changing the horizontal separation of any two lines in the flight direction the floating line can be made to rise or fall in the model, just as with the floating dot of the parallax bar. When the floating-line procedure is used in measuring stratigraphic thicknesses, a line is first floated preferably in the bedding plane at the upper formational contact, and parallax measurements are then made at the lower formational contact and on the floating line at a position in space vertically above this point (see fig. 27). If beds are horizontal or nearly horizontal the parallax difference will be approximately a measure of the stratigraphic thickness. If the beds dip, the stratigraphic thickness will bear a cosine relation to the dip angle and parallax measurement (see fig. 27).

Where dips are steep it may be desirable to measure a horizontal distance along a line at right angles to the strike direction between two formation contacts and relate this distance and dip angle to stratigraphic thickness. Points must be chosen at approximately the same altitude in the stereoscopic model (fig. 28).

ISOPACH MAPPING

The use of aerial photographs in studies of certain areas in the Colorado Plateau of Western United States has included the photogrammetric compilation of isopach maps that show local thickenings of certain formations in which uranium minerals are likely to occur. These thickenings of formations are channel-fill deposits in stream channels that were cut in the underlying formation. Uranium minerals are locally concentrated in these deposits. In the Monument Valley area of southern Utah it has been demonstrated that isopach lines, indicating the trends and thicknesses of different channel-fill deposits, could be drawn

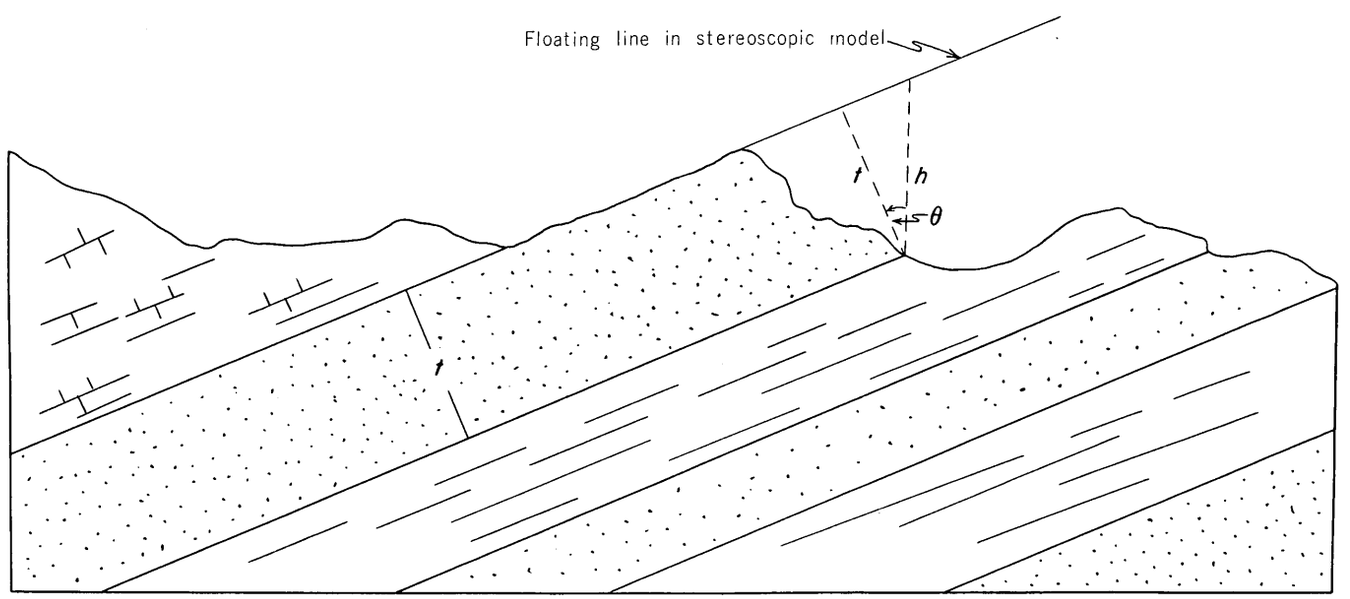

FIGURE 27.—Diagram of gently dipping beds showing relation of stratigraphic thickness to differential parallax determined by floating-line method.

Stratigraphic thickness is found from the formula

$$t=\frac{h}{\cos\theta}$$

where t=stratigraphic thickness;
h=difference in altitude between bottom of bed and point on floating line vertically above, as determined from the parallax formula;
and θ=angle equivalent to angle of dip.

on the basis of measurements made on vertical aerial photographs. In this area uranium minerals are present in channel-fill deposits at the base of the Shinarump member of the Chinle formation of Triassic age. However, because the top of the Shinarump member is eroded away in many areas, or because it is gradational with the overlying member of the Chinle formation, a stratigraphic unit below the Shinarump member was chosen as the unit for which isopach lines were drawn. A thinning of this underlying unit then was interpreted to indicate a thickening of, or channel deposits of, the overlying Shinarump member. The unit selected for isopach measurements, the Moenkopi formation, is expressed on aerial photographs as a dark-toned slope-forming unit that contrasts markedly with the light-toned cliff-forming units of both the underlying De Chelly sandstone member of the Cutler formation and the overlying Shinarump member of the Chinle formation (fig. 44).

A series of altitude measurements was then made along the contact of the Moenkopi and Shinarump formations from aerial photographs by means of the Kelsh plotter, and the locations of these measurements were plotted on a base sheet. Similarly, a series of altitude measurements was made along the contact of the De Chelly and Moenkopi formations and the locations were plotted on the base sheet. Measurements along the respective geologic contacts were generally spaced at horizontal distances of about 500 feet. Because the stratigraphic units dip locally it was necessary to compute the strike and dip of the beds and to correct for the dip angle in determining the stratigraphic thicknesses of the Moenkopi interval. Thickness computations were plotted at the points of altitude measurements along the contact of the Moenkopi and the Shinarump, and isopach lines were drawn at 10-foot intervals on the basis of the distribution of thickness figures. The relatively large number of readings, both for strike and dip of beds as well as for altitude measurements, permitted elimination of certain computations that were inconsistent with regard to the overall mass of statistical data. The locations and depths of channels of Shinarump member as shown by isopach lines based on photogrammetric measurements and plotting were generally in close agreement with those determined by field methods. Details of the photogeologic study are described by Witkind, Hemphill, Pillmore, and Morris (1960).

FACIES CHANGE

Measurements from aerial photographs in conjunction with stratigraphic studies of Cretaceous rocks in northern Alaska have demonstrated the rate and direction of "shaling," or facies change, of certain formations. In the Utukok-Corwin area resistant rocks of the Kukpowruk formation, which is predominantly silty shale, siltstone, and sandstone, overlie less resistant

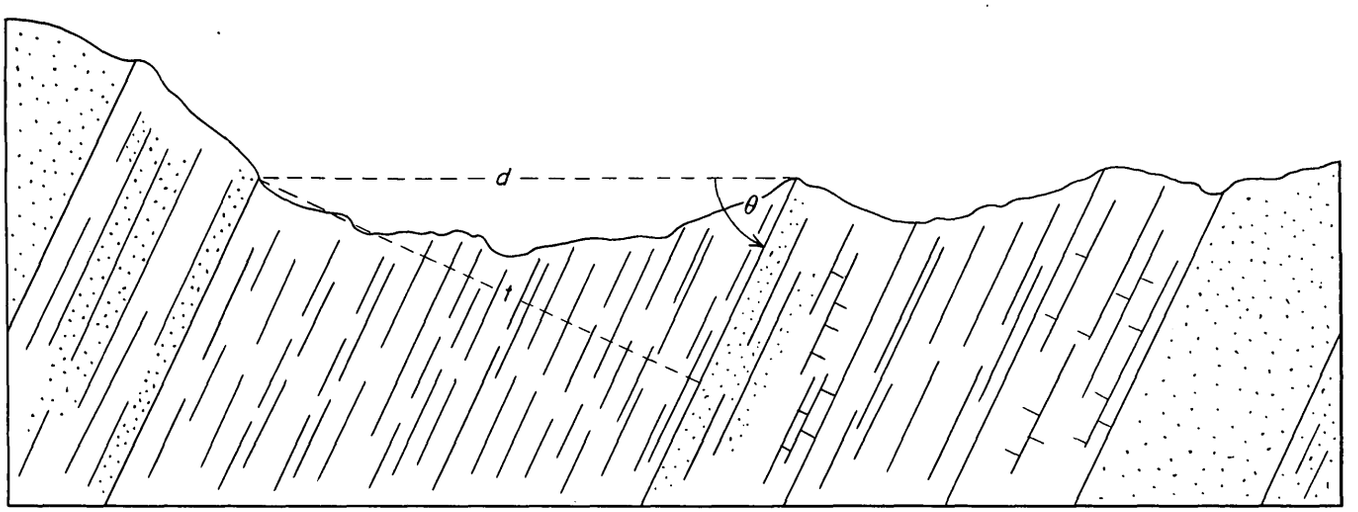

FIGURE 28.—Diagram of steeply dipping beds showing relation of stratigraphic thickness to dip angle and horizontal distance between top and botton of bed.

Stratigraphic thickness is determined from the formula

$$t=\frac{d}{\sin\theta}$$

where t=stratigraphic thickness;
d=horizontal distance at right angles to strike line between points at same altitude on top and bottom of bed;
and θ=angle of dip.

rocks of the Torok formation, which is largely clay shale, claystone, and silty shale. The Torok formation commonly forms the lowlands, which are characterized by rather uniform and low-dipping topographic slopes. The Kukpowruk formation forms high, resistant ridges that can be traced many miles. The contact of the two formations is marked by a break in topography that has been mapped in the field in conjunction with the study of aerial photographs. Slopes below the contact are generally smooth and unbroken; slopes above the contact are marked by conspicuous topographic breaks caused by hard, resistant sandstone beds in the basal part of the Kukpowruk formation. Vertical exaggeration of the stereoscopic model accentuates these topographic breaks in slope. Photogeologic and field studies show that these resistant beds pinch out usually in an easterly or northerly direction (see fig. 97). It is significant that their topographic expression is lost. Ground observations along stream cuts indicate that the resistant beds grade laterally into shaly sections.

Quantitative studies from aerial photographs of the amount of section affected by facies change in the Utukok-Corwin area show that several thousand feet of sandy section of the Kukpowruk formation grade laterally to the east and north into shale of the Torok formation. Chapman and Sable (1960) stated that the methods used in these studies included tracing on vertical aerial photographs a resistant unit within the Kukpowruk formation around the flanks of a large open structure and then measuring the stratigraphic intervals between the resistant bed and the contact of the Kukpowruk and Torok formations to determine the new relative stratigraphic positions of the contact in different parts of the area. Photogrammetric measurements were made whenever possible in localities of good field control; a few stratigraphic thicknesses were determined solely by photogrammetric methods without field control. Locations for measurements were chosen along east-west and north-south lines. Relative stratigraphic positions of the contact of the Kukpowruk and Torok formations were then plotted graphically against lateral distances between points of measurement; this resulted in a line whose gradient showed the average rate of rise of the contact between points of measurement. An average eastward-rising gradient of 58 feet per mile and an average northward-rising gradient of 97 feet per mile were calculated.

It was concluded on the basis of plotting these average gradients as vector quantities that a resultant maximum gradient of 115 feet per mile exists and that more than 10,000 feet of sandy beds grade into shaly sections over the area studied. The maximum gradient direction was further interpreted to lie at right angles to the direction of minimum facies change, which is believed to indicate the general trend of the old shoreline during the period of deposition of the Kukpowruk and Torok sediments. Thus the photogeologic measurement of stratigraphic intervals not only permitted determination of the directions and amounts of facies change, but further allowed inferences concerning the geologic history and environment, which may be significant in the search for petroleum in that area.

STRUCTURE CONTOURING

Structure contours are usually constructed on the basis of a series of spot altitudes, some of which may be photogrammetrically determined at the top of the horizon to be contoured, but many of which will be measured at formation contacts above or below that horizon. Photogeologic procedure is similar to field procedure and requires adjusting the altitudes of all points not on the horizon to be contoured by making appropriate considerations of strike and dip and stratigraphic thickness. Structure-contour lines are then adjusted to the resultant series of altitudes projected to the same formation contact.

NOTOM–15 QUADRANGLE

In photogeologic interpretation and mapping of the Notom-15 quadrangle, Utah, (Hackman and Tolbert, 1955) altitudes for structure contouring were measured using a Kelsh plotter. No previous geologic or topographic mapping had been done in the area; geologic data and altitude measurements were plotted to a control net established by photogrammetric methods. The Notom-15 quadrangle is well-exposed canyon country typical of the Colorado Plateau of Utah. Gently folded sedimentary rocks of Triassic and Jurassic age underlie the area. Canyons transecting the general structure trend made the application of photogeologic procedures ideal. A series of altitude measurements were made along the contact of the Wingate sandstone of Triassic age and the overlying Kayenta formation of Triassic(?) age. The wide exposure of this contact throughout the area permitted sufficient measurements to control structure contouring. Structure contours were then drawn on the top of the Wingate sandstone. Subsequent fieldwork corroborated the general structure as contoured by Kelsh plotter from aerial photographs and also corroborated the distributions of rock formation as interpreted and mapped from photographs. Positioning of other planimetric data, such as streams, was shown to be in excellent agreement with the subsequently compiled standard topographic map of the quadrangle. The positioning of data and altitude determinations by Kelsh plotter thus resulted in a highly reliable geologic map of the area.

DISCOVERY ANTICLINE

Procedures used in contouring the Discovery anticline in northern Alaska included stereometer measurement of altitudes combined with simple trigonometric computations and graphic constructions to compile a generalized structure-contour map (Marshall and Rosendale, 1953). These procedures contrast markedly with the Kelsh-plotter compilation of the Notom-15 quadrangle, but demonstrate that simple methods may be useful in obtaining structural information of a reconnaissance nature from aerial photographs.

Discovery anticline, a gently folded structural feature approximately 25 miles long and 7 miles wide, is underlain primarily by Cretaceous rocks. The area is generally covered with tundra grasses, but resistant beds within the stratigraphic section are expressed topographically as ridges, or breaks in slope, that can be traced for many miles; some beds are expressed by photographic tone due to differences in vegetation (see fig. 40). Dip slopes rarely coincide with topographic surfaces.

Procedures for obtaining and positioning data for structure contouring involved the arbitrary selection of cross-section lines normal to the general structural trend. Strikes and dips of beds were then determined by simple stereometer methods at numerous localities and projected to the nearest cross-section line. Where the strike line did not intersect the line of section at right angles the apparent dip was determined and plotted on the section line. This procedure was followed for all strikes and dips, and resulted in cross-section lines along which the different dips were plotted. A marker bed was then selected and its profile along the line of section graphically reconstructed on the basis of the positions and amounts of dip previously plotted (fig. 29). It was assumed that bedding throughout the stratigraphic section was parallel. Structure contours were then positioned along each line of section by further graphic constructions (fig. 30). However, the datum for each line of section commonly was different, depending on which part of the stratigraphic section was expressed in any one local area, and it was necessary to obtain stereometer measurements of altitudes between cross-section lines so that structure contours, as positioned along each line of section, could be tied together (fig. 31). The resulting reconnaissance map, plotted on an uncontrolled photomosaic, indicated the general magnitude and closure of the anticline and the attitude and steepness of bedding. Figures 29–31 show graphic constructions in reconnaissance structure contouring from measurements made with stereometer-type instruments.

DETERMINING DISPLACEMENTS ON FAULTS

The vertical component of displacement on some faults may be readily determined from parallax measurements made on marker beds on opposite sides of the fault by simple conversion of parallax difference to feet or other appropriate unit of measurement. If the fault plane dips, relative altitudes on marker beds may be related to the down-dip component of displacement by trigonometric or graphic solution.

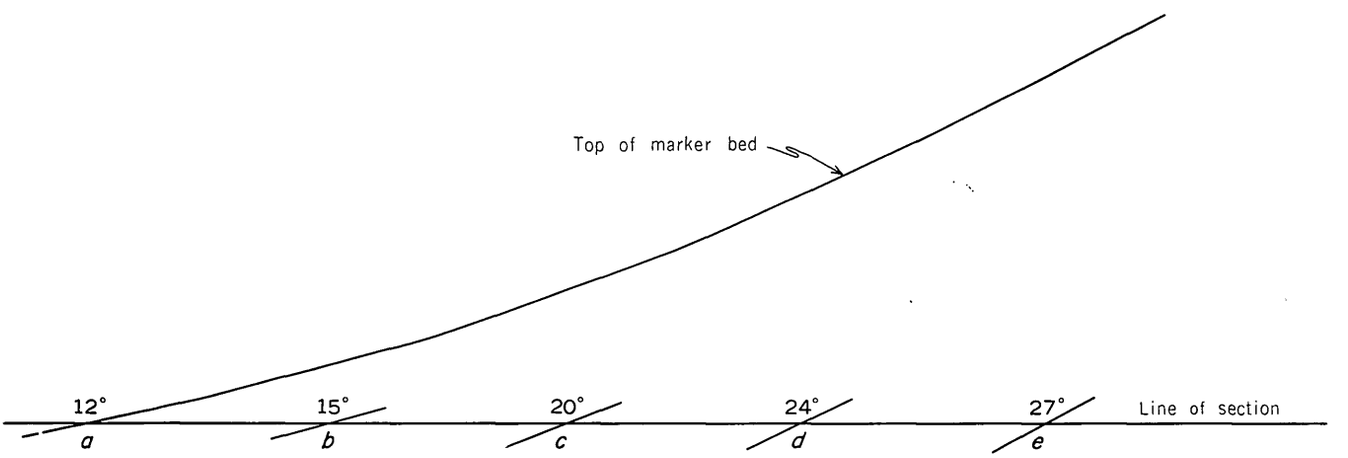

FIGURE 29.—Diagram showing graphic reconstruction of marker bed along line of section.

Dips determined from aerial photographs are first plotted along line of section. The marker bed is then reconstructed by extending bed upward from point *a* at 12° dip for half the distance between *a* and *b*. From this point the bed is extended at 15° dip to a point half the distance between *b* and *c*. From this point the bed is again extended at 20° dip to a point half the distance between *c* and *d*, and so on. A smooth curve is then drawn to represent the marker bed.

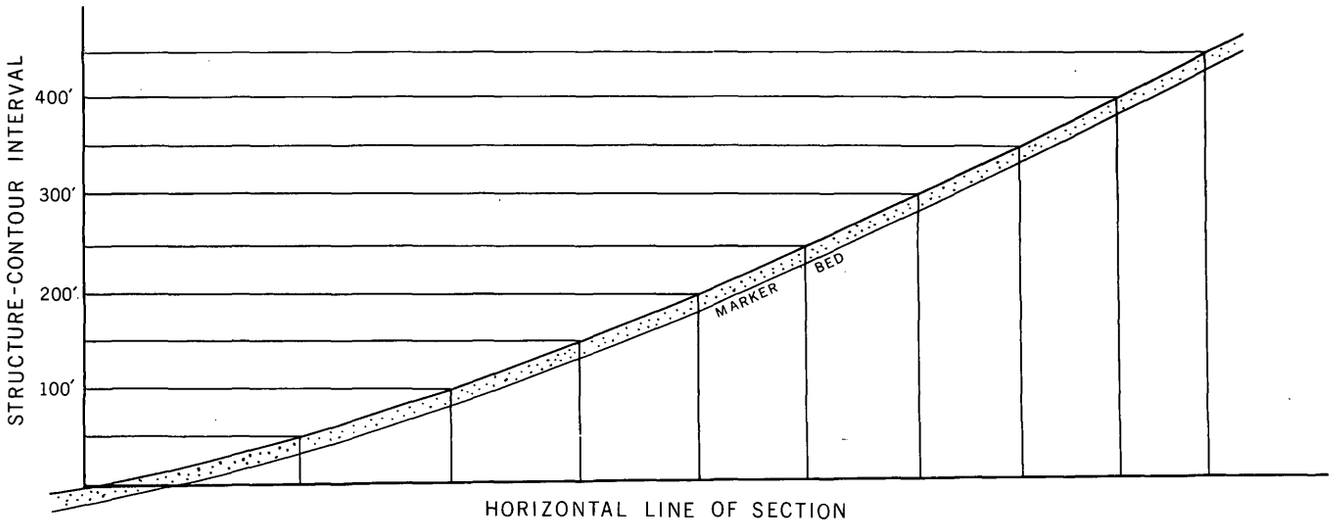

FIGURE 30.—Diagram showing graphic construction in positioning structure-contour lines on top of marker bed and the projecting of these lines to their relative horizontal positions along the line of section.

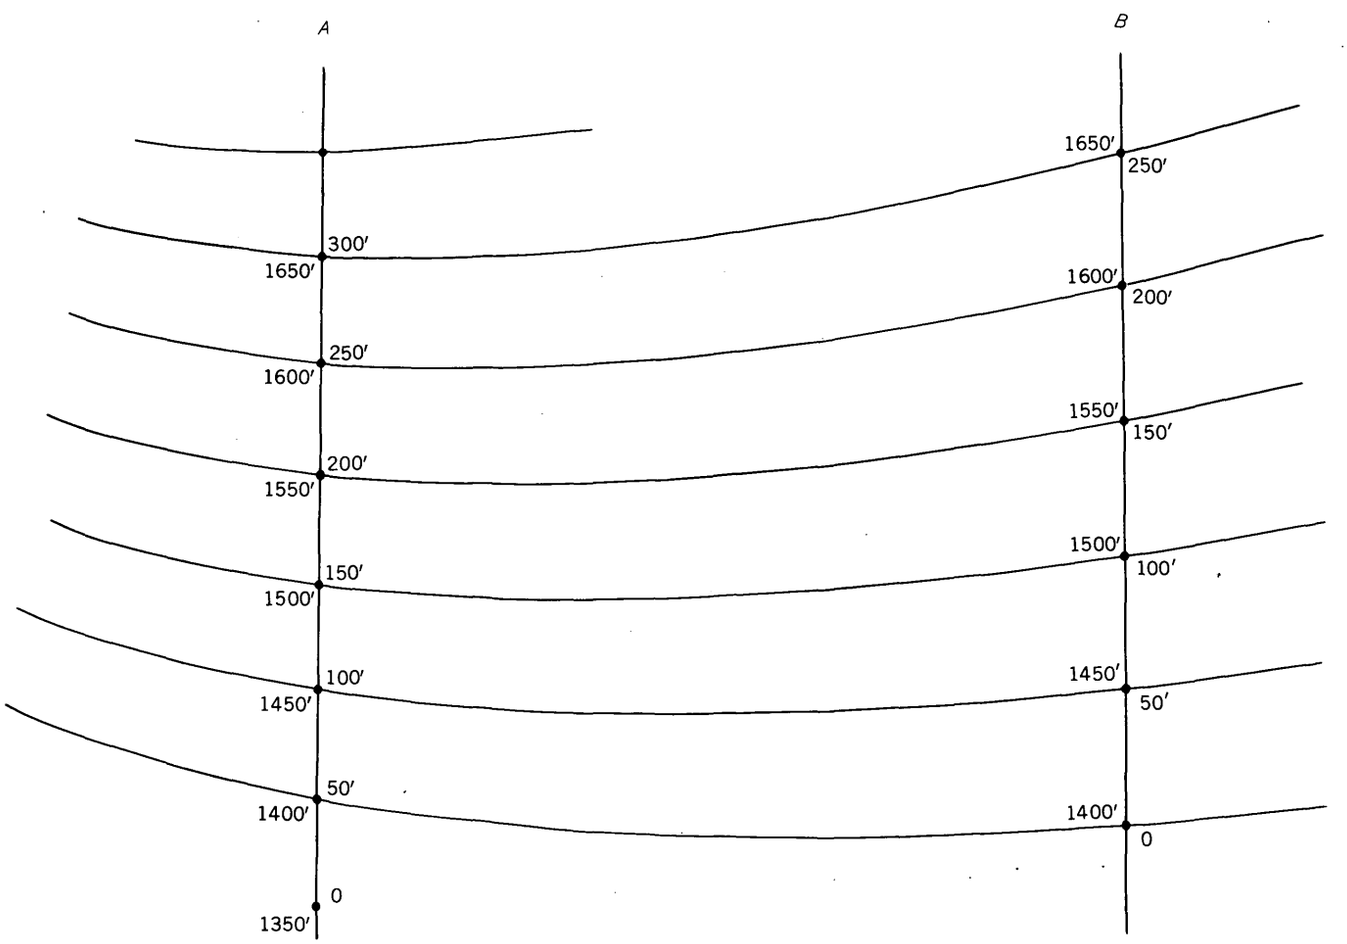

FIGURE 31.—Diagram showing relation of structure-contour positions along two lines of section at different altitudes.

Relative positions of 50-foot structure contours along each line of section are shown to the right of each line. Absolute altitudes of structure-contour positions are shown to the left of each line of section. Because the zero points on the reconstructed marker bed along lines *A* and *B* lie at 1,350 and 1,400 feet, respectively, it is necessary to connect the 50-foot contour position on line *A* with the zero contour position on line *B*, in compiling the structure-contour map.

DETERMINING STREAM GRADIENTS

Stream gradients may be calculated from parallax measurements under certain circumstances. Because many stream gradients are very low—a few feet or tens of feet per mile—an instrument should be used that will permit correction for tilt in the photographs. It will also be desirable to have vertical control for the removal of tilt, as a small amount of tilt not removed from the stereoscopic model could seriously affect the computation of stream gradient. If a stream has a meandering course, then the horizontal distance along the stream between points of measured parallax must be determined by a chartometer or similar instrument for measuring distances along a curved path.

DIRECT DETERMINATION OF SLOPE

DIPPING PLATEN

In addition to the indirect determination of slope by the use of parallax measurements in conjunction with trigonometry or graphic solution, direct measurements of some slopes may be made, both from glass-plate dispositives in double-projection instruments and from paper prints. The simplest procedure is with double-projection instruments and involves the use of a modified platen that can be tilted to coincide with the dip of a topographic surface or bedding plane (fig. 32). Because all features of the terrain are optically re-created in the stereoscopic model of double-projection instruments in essentially true relation, the dip of the platen when made to coincide with the ground surface, or to intersect three or more points on a bedding plane, will be a true measure of the dip of that surface. The dip can be measured with a clinometer attached to the platen or by an accessory device such as a "devil level" or Brunton compass. Dips below 40° can be readily obtained by this method, provided topographic expression or rock outcrops permit positioning of the platen. Dips greater than 40° are difficult to determine owing to the difficulty of positioning the dipping platen in the plane of a steeply dipping surface; steep dips should be computed using the parallax methods described above.

STEREO SLOPE COMPARATOR

A unique method for determining angles of slope from paper prints is employed with the stereo slope comparator (fig. 33), which was developed by the U.S. Geological Survey (Hackman, 1956b, p. 893–898). The instrument consists of two gear housings each containing a horizontal shaft on which small targets are mounted that can be fused stereoscopically into a single target. Swing of the horizontal shafts permits positioning the targets in any direction of strike. The gear housings are mounted on sliding tubes that permit the targets to be separated horizontally so that the fused target appears to rise or fall in space, just as the dot in stereometer-type instruments. However, the dip is determined by physical tilting of the target in space. The instrument is unique in that it measures the exaggerated dip of the imaginary slope created by stereoscopic viewing. With vertical photographs of normal 60 percent overlap, most individuals see the terrain exaggerated in height from 2.5 to 3.5 times. The exaggerated dip, recorded on a protractor attachment on the stereo slope comparator, must be reduced to a true dip. This is accomplished by reference to

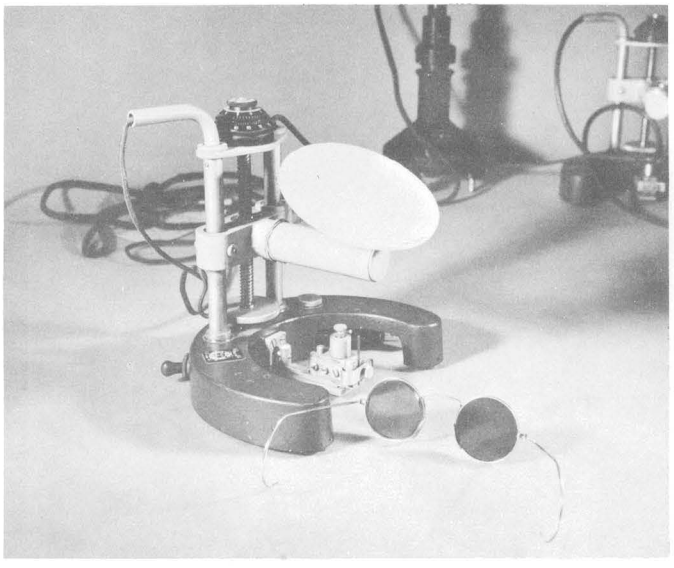

FIGURE 32.—Dipping platen.

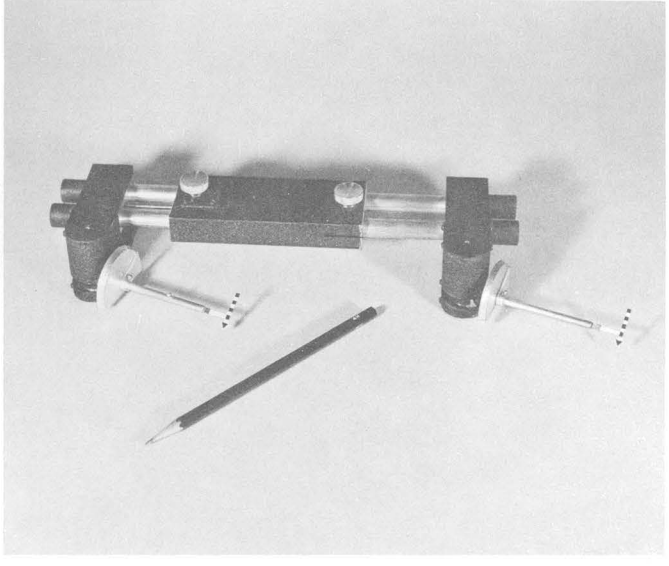

FIGURE 33.—Stereo slope comparator.

INSTRUMENTS FOR DIRECT DETERMINATION OF SLOPE

a slope-conversion graph made up of intersecting lines that represent true angle of slope, exaggerated angle of slope, and exaggeration factor (fig. 34). Construction of the graph is based on the relation

$$\text{Tangent true angle of dip} = \frac{\text{tangent exaggerated angle of dip}}{\text{exaggeration factor}}.$$

In determining dips from a pair of paper prints it is necessary to know the exaggeration factor of the interpreter for that stereoscopic model. This factor varies slightly with different individuals and is determined by reference to a supplementary slope chart on which a dipping surface of specific dip has been constructed by methods described by Hackman (1956a, p. 387–391). By measuring the exaggerated dip of this constructed surface, known to represent a given true angle of dip, an exaggeration factor is obtained; it is then possible to make measurements on a specific pair of photographs and to convert any exaggerated dip to a true dip. Because of the difficulty of placing the tilted target in a steeply dipping plane, the instrument is most reliably used where true dips are 20° or less.

DIP ESTIMATION

From paper prints an experienced interpreter can estimate dips, particularly in the range of 1° to 5°, with considerable reliability, as a result of vertical exaggeration in the stereoscopic model. Because of vertical exaggeration, angles of slope in terms of their tangent functions are exaggerated in the stereoscopic models as much as 2.5 to 3.5 times, with the result that low-dipping surfaces, which are in places difficult to observe in the field, are readily interpreted (figs. 45, 88, 90, 91, and 97). For example, a true dip of 1° may appear to be a dip of 3° or 4° in the stereoscopic model, and a dip of 5° may appear to be 15° to 20°. For true dips below 20° an error of a few degrees in estimating the exaggerated dip has only a small effect on the true dip (see fig. 35), and an interpreter is able to make reliable visual determinations of these dips from most stereoscopic models. But steeply dipping surfaces are also exaggerated and made more difficult to evaluate. Any small error in determining the angle of exaggerated dip of steep slopes results in a relatively larger error in the true dip calculation for that slope. Brundall and Harder (1953, p. 150) stated that "the accuracy of individual estimation is generally inversely proportional to the steepness of dip." In estimating dips a correction obviously must be made for the oversteepened slopes as they appear in the stereoscopic model (see figs. 34 and 35).

Factors affecting vertical exaggeration in stereoscopic models have been discussed by several writers (Treece, 1955; Goodale, 1953; Thurrell, 1953; Miller, 1953; Aschenbrenner, 1952; and Stone, 1951), but complete agreement has not been reached concerning the effects of specific factors such as viewing distance and image separation. However, once an interpreter has correlated amounts of dip, determined photogrammetrically or by field procedure, with a given set of conditions such as type of stereoscope, focal length of photography, photobase, and image separation, reliable estimates of true dip can be made over wide areas without reference to known dips.

OTHER METHODS OF DETERMINING ANGLES OF SLOPES

Another method of determining slopes in stereoscopic models is based on the floating-line principle. Brundall and Harder (1953, p. 150–151) briefly mentioned a device consisting of two lines scribed on plastic plates. The lines, seen stereoscopically as a single line floating within the model, can be made to converge so that the floating line appears to plunge in space. The plunging floating line is placed in the component of dip direction at right angles to the flight line. The angular rotation of the scribed lines required to obtain a given amount of steepness of plunge of the floating line is then related to true dip by means of a graph. As this method would result in true dip only for beds striking parallel to the flight line, the correction graph must also consider the azimuth of the dip component observed with respect to the strike of the beds.

Wallace (1950) has used angular relations in the plane of the aerial photograph as the basis for a method of determining strikes and dips from aerial photographs. The method is best applied where erosion has exposed bedding trace lines as contrasted to broad topographic surfaces that coincide with bedding. No parallax measurements are required. It is necessary to measure the angular relation of two bedding trace lines with respect to a known or assumed azimuth line on each photograph of a stereoscopic pair and to determine the plunge of the line of sight from the camera position to the outcrop, or bedding-trace line. These data are then plotted on a stereographic net to determine the strike and dip of the bed (Wallace, 1950, p. 275).

OTHER METHODS OF DETERMINING QUANTITATIVE DATA

Measurement of geologic data, other than altitudes and direct determinations of slope angles, are only infrequently made from aerial photographs. However, the possible applications of light-transmission measurements, from both black-and-white and color pho-

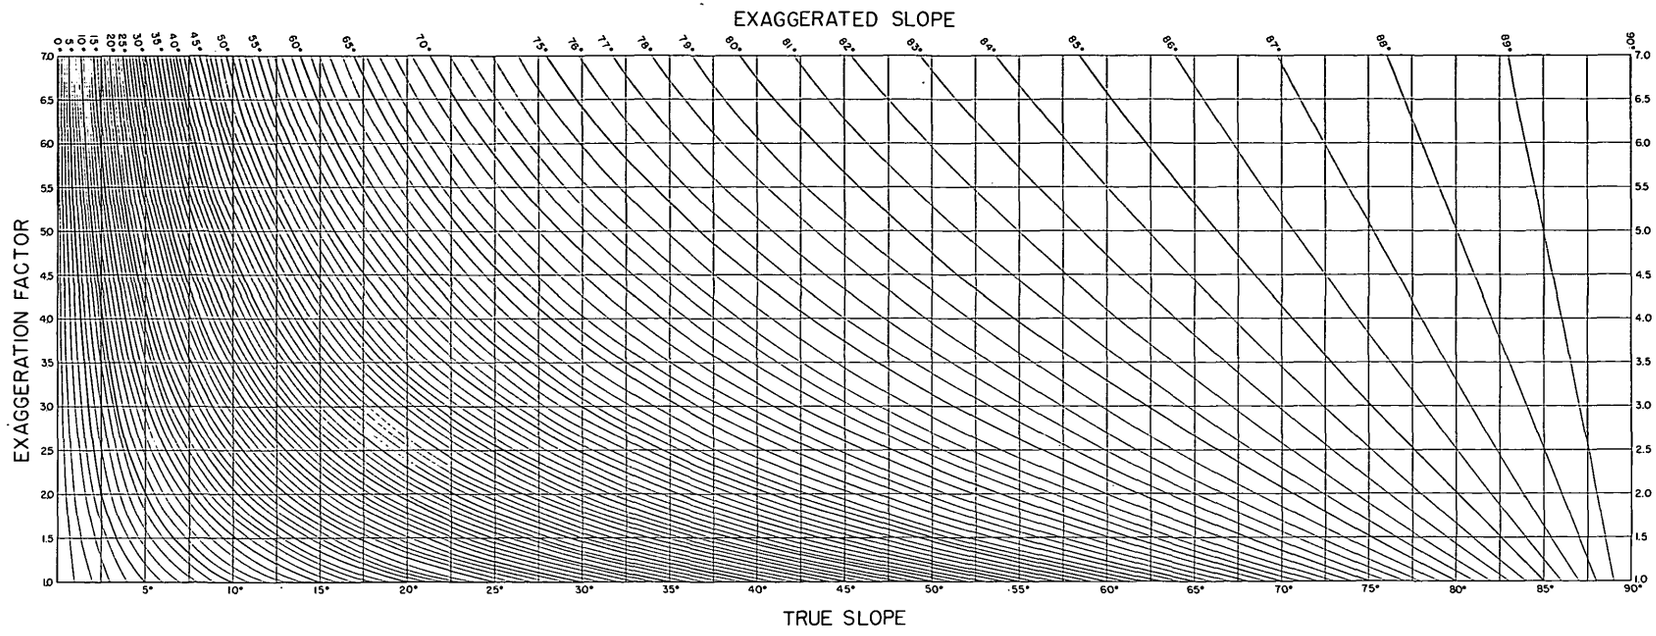

FIGURE 34.—Slope-conversion chart showing relation of exaggeration factor, exaggerated slope, and true slope.

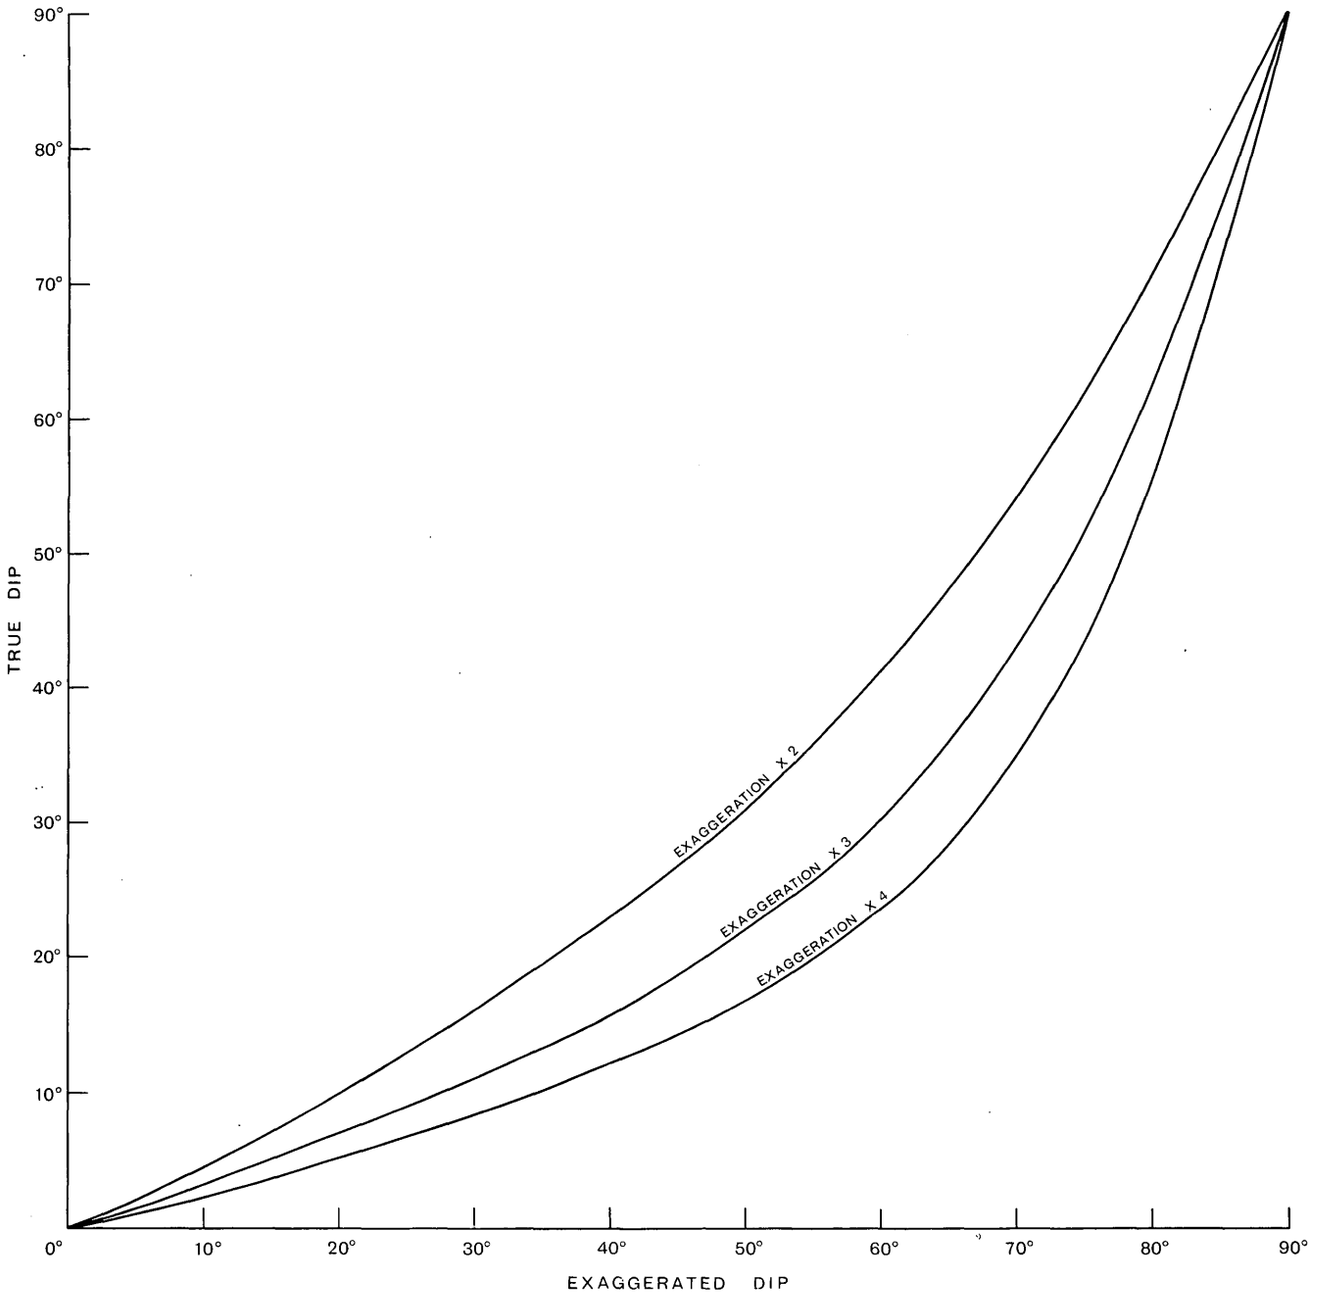

FIGURE 35.—Diagram, based on tangent functions, showing relation of true dips to exaggerated dips seen in stereoscopic models.

tography, light-reflectance measurements, measurements related to heat-retention characteristics of terrain photographed, infrared absorption, size, frequency, and orientation measurements of physiographic features, and perhaps others, offer challenging opportunities for future study (see Ray and Fischer, 1960).

PLOTTING

Map compilation—planimetric positioning of data—is basic to most geologic studies and generally requires methods of plotting data orthographically. Thus, data plotted or interpreted on vertical aerial photographs, most of which are perspective in view, must be replotted on an orthographic base. The orthographic base may be planimetric or topographic. Where no base map exists perspective aerial photographs provide a medium for constructing a control layout on which geologic and other data may be plotted orthographically.

CONSTRUCTION OF CONTROL LAYOUT

A control layout is an orthographic plot of a series of points selected on aerial photographs that cover a given area. These points are used to control the positioning of data plotted from the perspective photograph. Plotting, or transfer, of data from the photograph may be done with simple overhead projectors or sketchmasters under some circumstances, or with stereoplotting instruments described above. The accuracy of the final plot will depend primarily upon the control net and the instrument used in plotting (see p. 74–75).

Basically a control layout or control net is established by triangulation from the aerial photographs in much the same manner as field triangulation is carried out. This aerial triangulation requires mechanical construction of templets which are assembled together into the triangulation network. There are two general methods of constructing templets. One method involves radial triangulation using the principal point of the single photograph as a principal triangulation station to construct radial templets; the other method involves radial triangulation using some orthographically positioned pass point from the stereoscopic model as a principal triangulation station to construct stereotemplets.

Where single photographs are used for triangulation it is generally assumed that the photographs are truly vertical and have no tilt; relief displacement is radial from the photograph centers. However, a tilt of 1° or 2° does not significantly affect horizontal positioning over small areas. Templets from single photographs may be constructed by the hand-templet method, the radial-arm ("spider"-templet) method or the slotted-templet method. Photographs are first prepared by marking the centers, conjugate centers, and selected pass points, usually six in number, along the margins of a photograph; pass points are selected which are common to adjoining flight strips and common to succeeding and preceding photographs within the flight strip. From each photograph, azimuth lines are then constructed from the photograph center through all other selected points to form a templet for that photograph. Azimuth lines may be drawn in pencil on an overlay sheet (hand-templet method); they may be constructed of metal arms ("spider"-templet method), or they may be cut as slots in a piece of cardboard (slotted-templet method). After templets have been constructed for all photographs they are assembled into a triangulation network in which the intersections of azimuth lines locate the orthographic positions of the points selected. The result is a base sheet with a series of points located in their correct relative horizontal positions. Where horizontal control points are available, the distance between plotted positions of any two of them determines the scale of the control layout. Details of constructing and assembling these templets are described by Kelsh (1952, p. 419–429).

Construction of stereotemplets requires the use of a stereoplotting device to plot selected points common to adjoining flight strips and within the flight strip. The templet is actually a double templet of the area of the stereoscopic model rather than the single photograph. Azimuth lines are constructed for each part of the templet using one of the pass points as a principal triangulation station for one part of the templet, and using a different, generally diagonally opposite, pass point as the principal triangulation station for the second part of the templet. These two parts are joined together to form the completed templet for each stereoscopic model. Details of constructing and assembling the stereotemplets have been described by Scher (1955). Because of the longer base line of stereotemplets the resulting triangulation network is said to have a stronger scale solution than can be obtained from radial templets constructed from single photographs. Other photogrammetric advantages are mentioned by Scher (1955).

ORTHOGRAPHIC POSITIONING

PLOTTING ON ORTHOGRAPHIC BASE MAPS OR CONTROL LAYOUTS

The main objective in orthographic plotting of geologic data is to show the true planimetric relations of geologic features by removing relief and tilt displacement that may be present in perspective vertical aerial photographs. Relief displacement is commonly large, but tilt displacement is generally small and is usually disregarded when positioning geologic data on a planimetric base sheet. When positioning geologic data to a topographic base both relief and tilt displacement may be significant and require plotting from a leveled stereoscopic model. For horizontal positioning of data to a planimetric base in areas of low relief the relief displacement will be small; overhead projectors may be used to transfer data from the photograph to base map or control net. For example, with common photography of 1:20,000 scale taken with a 6-inch-focal-length lens, radial displacement near the edge of the photograph will only amount to about 0.1 inch where topographic relief does not exceed 300 feet. Basically relief displacement of a given amount of relief is a function of flying height and is independent of focal length and scale (see p. 74–75).

Where relief displacement is excessive it is possible

553966 O-60—4

to change the photograph scale by racking the overhead projector up and down and, provided base map control is sufficiently dense, to scale small areas of the photograph to the base, thus compensating for much of the radial displacement of the perspective photograph. The reliability of the final plot will be in part a function of the density of control points on the base. The suitability of the final plot will depend on the geologic objective. On most radial triangulation networks it is common to find eight control points, exclusive of the photograph center, for each photograph; this number of points will not normally be sufficient to give a reliable plot of the geologic detail in areas of moderate or high relief unless a stereoplotting instrument is used. The vertical sketchmaster, in which the image of a single photograph is seen superposed on the base map or control sheet, generally is used in the same way that overhead projectors are used in plotting. The same general limitations of the overhead projector apply to the sketchmaster; that is, radial displacement due to moderate or high relief cannot be effectively removed.

Orthographic plotting may also be accomplished with the radial planimetric plotter (fig. 14), or with the more complex paper-print plotters, such as the KEK or Mahan plotters. (See p. 42, 45). The radial planimetric plotter is the simplest to operate. It is easily scaled to control points on the base map or triangulation network and effectively corrects for the radial displacement of vertical aerial photographs. Fine detail, such as the configuration of reentrants in contact lines, may be lost in plotting, however. Tilt inherent in photographs cannot be eliminated, but horizontal positioning due to small amounts of tilt found in present-day photography do not significantly effect horizontal positioning of photographic detail for most geologic interpretations. The KEK and Mahan plotters may also be used to plot geologic data from paper prints. These instruments permit compensation for any inherent tilt that may be present in the photographs but are more difficult to operate than the planimetric plotter.

Whenever paper prints are used in plotting or transferring geologic data to base maps or control sheets it may be desirable to annotate, or mark, the geologic features to be transferred. This is particularly desirable when overhead projectors are used and is usually a necessity for all instruments if someone other than the interpreter is to do the plotting.

Double-projection instruments afford a high degree of reliability in plotting geologic data from aerial photographs. The ability to correct for tilt and relief displacement combined with an enlarged view of the stereoscopic model when the Kelsh, multiplex, or ER–55 plotters are used permits a highly reliable compilation of geologic data. Even when vertical control is lacking, it is possible to remove most of any tilt inherent in the stereoscopic model by careful reference to physiographic manifestations of tilt such as oversteepened or reverse stream gradients, tilted meanders of a stream, or tilted bodies of standing water (see p. 55).

True orthographic positioning is not always attained, however, in geologic compilations from aerial photographs. Not only is there a question at times of the reliability of interpretation because of the subjective nature of much photogeologic study, but the various instruments themselves have differing degrees of accuracy inherent in their construction. Positioning of clearly identified geologic features by overhead projector, which does not permit adjustments for tilt or effective removal of relief displacement, would be far less reliable under most circumstances than positioning by double-projection instruments. However, the geologic product sought should determine in part the procedure to be used in plotting. Normally there is no reason to use an instrument that will plot detail more accurately than is needed to satisfy the geologic requirement. For example, in small-scale reconnaissance mapping, it is hardly necessary to use a precision plotting instrument for horizontal positioning. The problem of instrument requirement in relation to the geologic problem is further considered under a discussion of interpretation and plotting systems (see p. 69–75).

Only where a significant saving in time and money can be shown is it justifiable to use an instrument whose capability exceeds the minimum requirements of the geologic problem. Such a condition may exist for example where small-scale photographs of an area are available. Much of the United States is now covered by photographs at a scale of approximately 1:60,000. The use of such small-scale photographs in an instrument such as the Kelsh plotter may reduce by as much as 90 percent the number of stereoscopic models that would normally be oriented for interpretation, measuring, and plotting if 1:20,000-scale photographs were used. Even when 1:20,000-scale photographs are used with simple instruments the common practice is to separate the operations; that is, the stereoscope is used to interpret geologic detail and another instrument, such as the stereometer, is used to determine vertical measurement. Thus, by using a precision plotter, which combines interpretation, measuring, and plotting, a significant saving in time and money may be expected.

PLOTTING ON ORTHOPHOTOGRAPHS

An orthophotograph is a photograph that has the position and scale qualities of a map. In addition it has the abundant imagery of the conventional perspective photograph and hence a wealth of photographic detail (fig. 47). Theoretically the orthophotograph, with tilt and radial displacement eliminated in preparation (Bean and Thompson, 1957), has the desirable detail of a photograph and the geometric characteristics of an accurate planimetric map. The method of constructing the orthophotograph from double-projection stereoscopic models results in a small loss of photographic resolution, but horizontal positioning accuracy is comparable to that of the standard topographic map of the same scale.

The orthophotograph, when viewed with an alternate perspective aerial photograph, forms a stereoscopic model, although with only a small amount of stereoscopic relief as contrasted to viewing two perspective photographs. In viewing an orthophotograph with a perspective photograph it is generally best to use the same perspective photography as was used in the preparation of the orthophotograph. Combining the orthophotograph with a perspective photograph permits plotting of geologic detail from the perspective photograph to the orthophotograph and gives a reliable photomap. Geologic data on the orthophotograph then can be transferred by direct projection to a topographic or other base, if desired, or merely traced off to give a reliable planimetric map of areas where no base maps exist. As an aid to field geologic mapping, in which a daily plot of observed data is desirable, the orthophotograph may be especially helpful.

The range of potential applications of orthophotography has been summarized by Bean and Thompson (1957, p. 178) who stated that "* * * whenever there is an advantage in being able to determine accurately on an aerial photograph the positions of points, the lengths or directions of lines, the courses of curved lines, or the shapes or areas of given tracts, the orthophotograph offers a potential means of accomplishing the desired end." In addition, as the basis for constructing mosaics the orthophotograph has a significant application, especially in areas of moderate or high relief.

PLOTTING ON GRIDDED BASE MAPS

Gridded base maps may be especially valuable for field plotting of geologic data without the assistance of photogrammetric instruments. In constructing a gridded base map a grid made up of small squares, usually 1 centimeter on a side, is first superposed photographically onto the perspective aerial photograph. The same grid is then orthographically transferred to the base map by a photogrammetric technician using stereoplotting instruments (Landen, David, oral communication, 1958). The grid lines are straight as superposed on the perspective photograph but are curved on the base map (figs. 115 and 116). By dividing the photograph into many small grid squares the effects of tilt and relief displacement become so small as to be negligible within any one square. Information sketched within grid squares on the perspective photograph is transferred visually to the base map by matching grid squares on the photograph with those on the map. The method may be especially useful in the field where it is desirable to keep a compilation of each day's work.

VERTICAL POSITIONING IN CROSS SECTIONS

In addition to the orthographic positioning of photogeologic data on base maps it is commonly desirable to plot geologic cross sections. The third dimension of the stereoscopic model is then added in part to the normal two-dimensional planimetric presentation of geologic information. Vertical positioning of geologic data, as shown in cross section, may be helpful to the geologist interpreting the aerial photographs of an area, as well as to the map reader who may be less familiar with the geology of the area.

Cross sections are easily and rapidly constructed with a profile plotter from streoscopic models in double-projection plotters. Modification of the tracing table permits profiles to be drawn in any direction within the stereoscopic model (figs. 19 and 20). Sections may be drawn at a horizontal-vertical ratio of 1:1 or they may be exaggerated as much as 5 times. When a 1:1 ratio is used, dips of beds or components of dip, stream gradients, thickness of beds, and similar data may be obtained directly from the section. Exaggerated profiles may be desirable where relief of terrain is low, or, for example, when interpreting the significance of vertical position of thin stratigraphic units in correlation studies. Vertical positioning in sections may also show information suggesting the presence of faults.

INTERPRETATION, MEASURING, AND PLOTTING SYSTEMS

An interpretation, measuring, and plotting system (see fig. 36) may be defined as a combination of photographs and instruments that will permit attaining specific qualitative and quantitative geologic information from stereoscopic models. The optimum system is generally achieved by combining the minimum

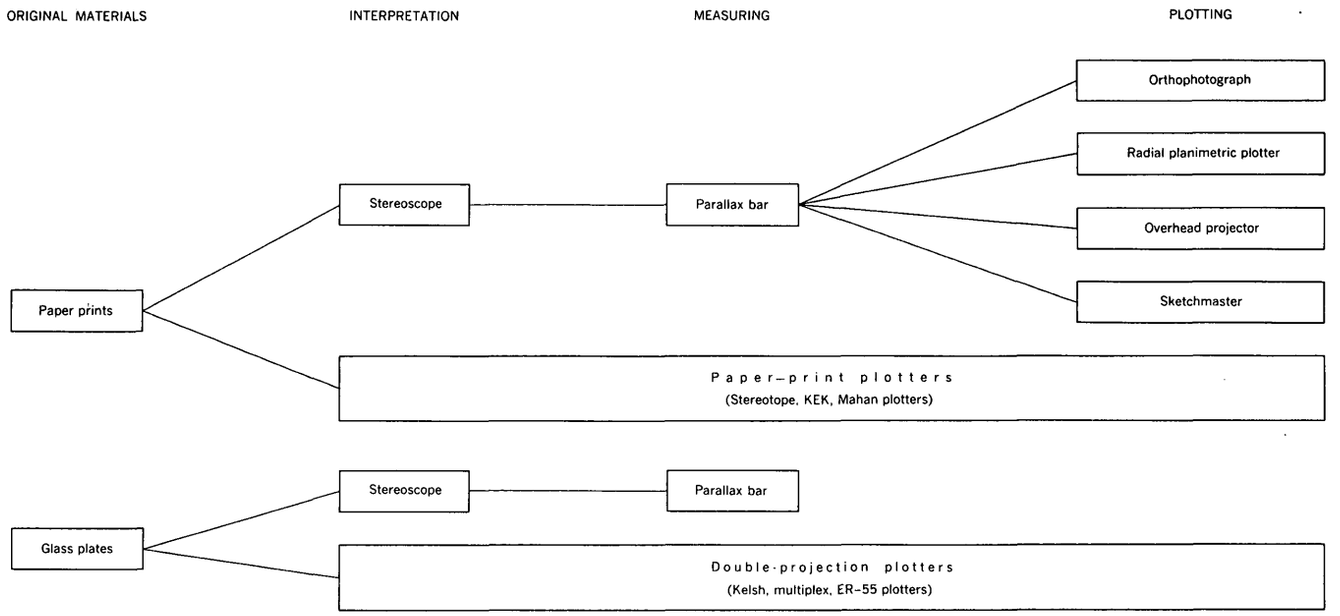

FIGURE 36.—Photogrammetric systems for geologists.

scale photographs and minimum instrument capability that will provide the desired geologic measurements within given accuracy requirements. That is, the scale of photographs should be the smallest that will permit differentiation of photographic detail needed for qualitative interpretation, as well as the smallest that will permit photogrammetric measurements within specified limits. Fundamentally, the geologic objective of a particular study is the controlling factor in the choice of the optimum system of interpretation, measuring, and plotting. The geologic objective may permit the use of existing instruments and photograph scales or it may necessitate new photography or instruments to attain given accuracy requirements.

The type of geologic map and its intended use—the geologic objective—can be considered on the basis of accuracy requirements or limits of error, both in obtaining vertical measurements and in plan positioning of geologic features, provided photographic detail is adequate for qualitative interpretation. For example, a detailed structure-contour map may require an accuracy of vertical measurement within ± 5 feet of altitude and a horizontal position of geologic features within 1/25 inch of true map position. In contrast a small-scale structure-reconnaissance map for planning purposes may permit a vertical tolerance of ±50 feet and have only general horizontal positioning requirements. Thus the choice of an interpretation, measuring, and plotting system may be reduced to certain mathematical requirements that can be satisfied by combining instrument capability with appropriate photography; or the geologic objective or tolerances of measurement may be modified to permit the use of existing photography and instruments.

However, geologic maps, unlike topographic maps, have no standard accuracy limits except those imposed by the individual geologist, with the one exception in the Geological Survey that solid lines, representing faults, contacts, or similar geologic features, should generally be within 1/25 inch of their correct map positions for general geologic maps at a scale of 1:63,360 or larger. Horizontal positioning of data within 1/25 inch of true map position may be accomplished with almost any plotting instrument or plotting system, especially if relief of the area is low and excessive tilt is not present in the photographs. Hence, the vertical-accuracy requirement specified by the geologist for a given geologic problem is ideally the determining factor in choosing an interpretation, measuring, and plotting system. This accuracy requirement, as well as the maximum range of measurements expectable for any system, may be equated against instrument capability and photograph scale as follows:

Geologic requirement of vertical-measurement accuracy
or
Expected maximum range of vertical-measurement error
$\rightleftarrows$
Instrument capability in terms of K and V factors (see fig. 37).

Figure 37 is an elaboration of this equation and shows the general relations between the geologic requirements of vertical accuracy or expected maximum error in measuring spot altitudes or vertical intervals

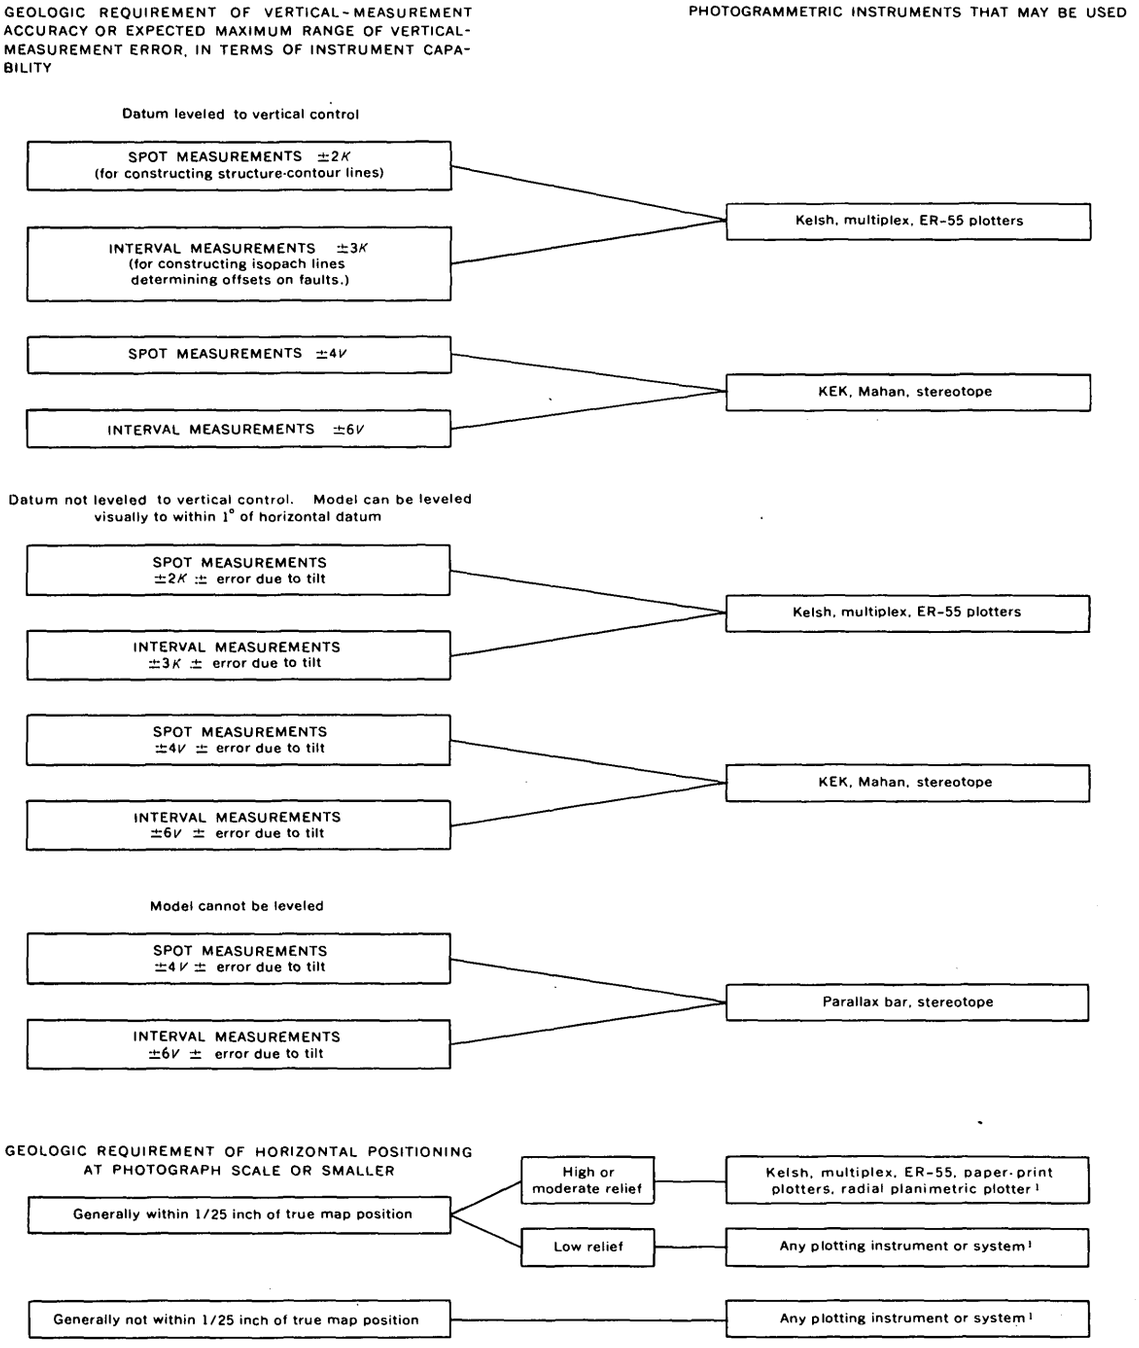

FIGURE 37.—Photogrammetric measuring and plotting systems for geologists showing relation of different instruments to vertical-measurement and horizontal-positioning errors.

where K factor = difference in altitude, in feet, on the ground per unit of vertical measurement in an anaglyphic-type model, that is, per 0.1 millimeter

$$= \frac{\text{model-scale denominator}^2}{3{,}048}.$$

where V factor = difference in altitude, in feet, on the ground per unit of measurement from a parallax bar or a paper-print plotter, that is, per 0.01 millimeter

$$= \frac{\text{flying height (feet)}}{\text{photobase (millimeters)} \times 100}.$$

[1] No excessive tilt assumed to be present for paper-print models that cannot be leveled.

[2] Model scale for Kelsh plotter is usually about 5 times original photography scale; for ER-55 usually about 3.5 or 5 times, depending on the projector model; and for multiplex usually about 2.5 times.

in terms of instrument capability on one hand and photogrammetric instruments that may be used for measuring and plotting on the other hand. The determination of spot altitudes or relative vertical intervals satisfies most geologic requirements of altitude measurements from stereoscopic models and permits construction of structure-contour lines, and isopach lines, and the determination of dips of slopes, displacements on faults, and similar data. Figure 37 can be used in choosing the best selection from existing photograph scales and instruments for measuring vertical distances, or it can be used to determine what combination of photograph scale and instruments would be optimum in making vertical measurements within certain specified tolerances. For economic reasons the geologist more often than not will be concerned with the best selection of existing photographs and instruments but this selection may not be the optimum interpretation, measuring, and plotting system. This may require modification of his geologic objective, at least in reporting the limits of measurement.

INSTRUMENT CAPABILITY

Instrument capability, selected as the principal basis for the systems shown in figure 37, is an empirically derived factor generally considered with respect to topographic mapping systems as the minimum contour interval—stated in terms of a fraction of the flying height—that can be plotted to fulfill certain accuracy requirements. For geologic measurements it is desirable to consider instrument capability as the minimum increment of vertical measurement that generally can be determined by the geologist from the stereoscopic model. This permits a simple evaluation of expected maximum errors in geologic measurements when double-projection stereoscopic models are used, or when stereoscopic models from paper prints are used. It also allows the geologist to determine what photograph scale and instrument combinations will give him a desired accuracy of measurement. Because the minimum increment of vertical measurement is empirically derived, the limits of error for vertical measurements described below may be subject to modification.

To determine the expected maximum error for a given combination of photograph scale and instrument three possible individual errors must be considered. These are (a) instrument capability in terms of the geologist's ability to measure horizontal linear parallaxes and increments of vertical measurement, (b) curvature of the datum within a stereoscopic model when double-projection instruments are used, or paper and lens distortions when paper prints are used, and (c) tilt. Consideration of the cumulative effect of all three possible errors is necessary in determining the expected maximum error for a particular measuring and plotting system, except for leveled models where tilt has been eliminated. In measuring spot altitudes or relative intervals these errors may be compensating rather than cumulative and therefore many measurements will be well within the expected maximum error determined for a particular combination of photograph scale and instrument.

Experience has shown that for double-projection plotters, it is generally possible for the geologist to determine any one reading to one unit of vertical measurement. One unit of vertical measurement is equal to 0.1 millimeter. With care the increment of measurement may be read closer than one unit of vertical measurement. The amount of altitude difference, in feet, on the ground represented by one unit of vertical measurement in the model—called the K factor—depends solely on the scale of the projected stereoscopic model, and is determined by the ratio

$$\frac{\text{Model-scale denominator}}{3{,}048}.$$

This factor is constant throughout the stereoscopic model. Hence spot altitude readings generally may be read within an amount equal to $\pm K$, that is, the geologist may read a point one unit (0.1 millimeter) too high or one unit (0.1 millimeter) too low. In addition, an error of $\pm K$ is added for curvature of the model datum. Thus the maximum error for spot altitudes can be expected to be on the order of $\pm 2K$ for models leveled to vertical control. Where errors due to reading and to curvature of the datum are compensating a minimum error approaching zero can be obtained. For interval measurements the altitudes of two image points in the stereoscopic model of course must be measured. Each point may be read within an amount equal to $\pm K$, or a total reading error $\pm 2K$. Curvature of the model datum may affect the reading of each point a similar amount and can be disregarded when relative intervals are measured on points close together in plan view; for points close together the expected maximum error generally will be similar to that for spot altitudes. But if points of measurement are not selected close together an added error of $\pm K$ due to datum curvature may be introduced. Thus the maximum error for relative interval measurements is on the order of $\pm 3K$ (figs. 37 and 38).

When vertical control is absent many double-projection stereoscopic models and some models from paper prints may be leveled visually to within 1° of a horizontal datum by observing certain physiographic

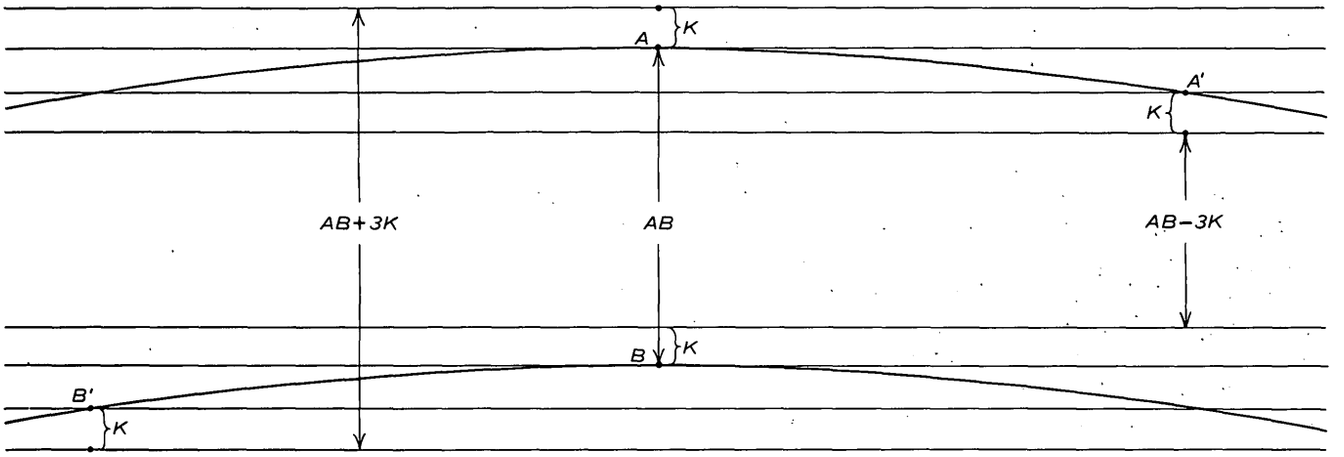

FIGURE 38.—Diagram showing datum-curvature relation to maximum expected error in measuring vertical intervals from leveled double-projection stereoscopic model.

Let AB equal the interval desired. If the upper point is measured at A' an error equal to $-K$, or one unit of measurement, may result from datum curvature; when point B' is measured an error of $+K$ may result. If points A and B' are chosen for measuring the interval and point A is measured one unit too high (equivalent to $+K$) and point B' is measured one unit too low (also equivalent to $+K$) a maximum expected error, including datum-curvature error, of $+3K$ may result. Likewise if points A' and B are chosen for measuring the interval a maximum expected error, including datum-curvature error, of $-3K$ may result.

features in the model (see p. 55) and making appropriate instrument adjustments. For double-projection stereoscopic models that are leveled visually some error due to tilt thus may be present in addition to possible errors in reading and curvature of the model datum; the order of maximum error for spot altitudes becomes $\pm 2K$ ± error due to tilt, and for relative interval measurements becomes $\pm 3K$ ± error due to tilt. When relative stratigraphic thicknesses, displacements on faults, or similar geologic measurements are being made, errors due to tilt or from curvature of the model datum may be minimized by measuring points close together in the stereoscopic model. For points spaced far apart the error due to tilt can exceed the error in reading intervals.

Limits can also be placed on reading units of measurement with paper-print plotters or parallax bars, except that a V factor rather than a K factor is employed. A differentiation of factors is necessary as the V factor, unlike the K factor, is not constant throughout the model, but varies slightly due to differences in scale at different altitudes in models formed from paper prints. For practical purposes, V is the ratio:

$$\frac{\text{Flying height (feet)}}{\text{Photobase (millimeters)} \times 100}$$

The V factor represents the difference in altitude in feet on the ground per unit of measurement from a parallax bar or paper-print plotter, that is per 0.01 millimeter. Experience has shown that parallax measurements from paper prints may be read within about ± 0.02 millimeter or $\pm 2V$. Considering possible errors due to paper or lens distortion and due to tilt, total expected errors for spot altitudes and relative intervals may be determined as shown on figure 37. (See also p. 74.) Errors resulting from paper and lens distortions are considered to be equivalent to about two units of measurement or about $2V$.

Thus two different factors are considered in relating geologic accuracy requirements or expected maximum vertical measurement errors to photograph scale and instrument capability. These factors are the K factor for use with stereoscopic models from glass plates in double-projection plotters, and the V factor for use with stereoscopic models formed from paper prints. For any given system of measurement it is likely that many measurements will fall well within the expected maximum errors as determined from figure 37, especially if high-resolution photographs are available that may permit reading units of vertical measurement less than K or V, and if points of measurement are carefully chosen. Also, errors of reading and datum curvature or tilt may be compensating rather than cumulative, as stated above. In a recent test of determining altitudes of gravity stations with multiplex leveled to vertical control, Kinoshita and Kent (1960) found that 96 per cent of the points measured fell approximately within the limits of $\pm K$ and that 71 percent of the points measured fell approximately within the limits of $\pm K/2$. Results of this special test do not represent the general order of vertical ac-

curacy that geologists may expect to obtain by photogrammetric methods, but they do suggest that many measurements made will be well within the limits shown in figure 37.

RELATION BETWEEN INSTRUMENT CAPABILITY, SCALE, AND VERTICAL MEASUREMENTS

Let it be desired to determine the accuracy of spot altitudes for compiling a structure-contour map of an area covered by recent, high-quality 1:20,000-scale photography flown at 10,000 feet. Adequate vertical control is available for leveling stereoscopic models and a Kelsh plotter is available for measurement and compilation. The expected maximum error shown in figure 37 for spot altitudes for leveled models is $\pm 2K$. Because the scale of the Kelsh model is approximately 5 times that of the original 1:20,000-scale photography (fig. 37), a projected stereoscopic model at a scale of 1:4,000 would result. Thus the K factor for this model would be 4,000/3,048 or 1.31 feet (fig. 37). Spot altitude measurements could be expected to be correct within $\pm 2K$ or ± 2.62 feet for most points in the model.

Many geologists will have only paper prints and simple measuring devices to use so as a second example let it be desired to determine the expected maximum error in measuring a stratigraphic interval with a parallax bar and paper prints already available. Photographs at a scale of 1:20,000 and taken at 10,000 feet are available. Inspection of physiographic characteristics of the terrain indicates that very little tilt, estimated not to exceed 1°, is present. Rock units are clearly expressed, the formations are essentially flat lying, and points of measurement are within ¼ inch on photographs or a distance of about 400 feet on the ground. The photobase distance is 90 millimeters. Figure 37 shows that with parallax bar the expected range of error for relative intervals is $\pm 6V$ ± error due to tilt,

$$\text{where } V = \frac{10{,}000}{90 \times 100} = 1.1 \text{ (fig. 37)}.$$

The maximum error due to tilt, however, could amount to 14 feet in this example and thus a total expected error of 20.6 feet could result. But the reading error plus paper and lens distortion error may well be less than $\pm 6V$ and the points of measurement may well lie in a direction other than the maximum tilt direction; thus, a measurement error of much less than 20.6 feet will probably result. Figure 37 is constructed to show only the order of maximum error. The percentage of error will depend on the total thickness of the stratigraphic interval; the percentage of error becomes smaller as the thickness of the interval increases.

The geologist will be concerned generally with the expected maximum error of measurement that photographs and instruments already at his disposal will give, and figure 37 is readily used to determine expected maximum errors of measurement for a given photograph scale and instrument combination. However, to determine what photograph scale and instrument combination would be needed to attain specified accuracy requirements is not so easy, as the photograph scale and instrument may be varied and yet give the same required tolerances of vertical measurements. For practical purposes it may be best to equate the vertical-accuracy requirement against instrument capabilities, and to determine from this the scale of photographs that would be needed. Thus, if a requirement for measuring vertical intervals of ±5 feet is specified it can be seen, for leveled double-projection stereoscopic models, for example, that $\pm 3K$, the maximum expected error for relative intervals, must equal 5 feet or K must equal 1.66 approximately. It follows (see fig. 37) that the projected model-scale denominator must equal 1.66×3,048 or about 1:5,000.

The scale of photographs required to provide a projected stereoscopic model of 1:5,000 depends on the double-projection plotter used. For the Kelsh plotter, the original photography scale would be approximately 1:25,000; for the ER–55 plotter, approximately 1:17,000 or 1:25,000 depending on the projector model; and for the multiplex, approximately 1:12,000 (fig. 37). Similar computations can be made for other instrument capabilities and requirements of vertical measurements. Where two different combinations of instruments and photograph scales will provide the desired accuracy of vertical measurement, the optimum interpretation, measuring, and plotting system will be determined by the smallest scale of photography that will allow recognition and qualitative interpretation of geologic features pertinent to the given geologic objective.

HORIZONTAL POSITIONING

Horizontal positioning within 1/25 inch of true map position generally can be accomplished at photograph scale or smaller with any of the plotting instruments that removes relief and tilt displacement. Such instruments include the double-projection plotters and some of the paper-print plotters. The small amount of tilt inherent in present-day vertical photography is generally of little significance in horizontal positioning of geologic features, however, and the radial planimetric plotter may also be used to plot geologic features within 1/25 inch of true map position. Orthophotographs may also be used for reliable horizontal positioning of data (see p. 69). In addition, geologic features in areas of

low relief may be plotted within 1/25 inch of true map position by sketchmaster or overhead reflecting projector if tilt is negligible. Where relief is low, radial displacement (also called relief displacement) of image points is commonly less than $\frac{1}{25}$ inch. For example, on vertical photographs taken from a flying height of 10,000 feet, displacement where the relief is 100 feet amounts to 1/25 inch at a point 4 inches from the center of the photograph. Nearer the center of the photograph the displacement is less. Thus, geologic data on such photographs can be plotted generally within 1/25 inch at photograph scale or smaller with simple overhead reflecting projectors, or can even be traced directly from the photographs and still be within the 1/25-inch tolerance for general geologic maps. The amount of radial displacement, m in inches, is determined from the formula

$$m=\frac{rh}{H}$$

where r=radial distance on the photograph, in inches, from principal point to base of image displaced;

h=height of object displaced, in feet above datum (height of terrain);

and H=flying height, in feet, above datum;

(h and H must be referred to the same datum and be measured in the same units. The amount of displacement, m, is then in the same units of measure as chosen for r). Thus, the limit of relief that can be adequately plotted within the 1/25-inch tolerance for general geologic maps is basically a function of flying height and not of focal length. Displacement due to relief varies inversely with flying height.

FIGURE 39.—POORLY RESISTANT PYROCLASTIC ROCKS OVERLAIN BY RESISTANT CAPPING FORMATION (COLORADO).

[Approximate scale 1 : 20,000. Photographs by Soil Conservation Service]

Coarse pyroclastic rocks, *A*, are highly dissected in contrast to the more resistant and protecting welded tuff caprock, *B*, in this area of flat-lying formations. Deep dissection of pyroclastic rocks, occurring here preferentially on one slope, permits delineation of contacts that can be traced into nearby areas where strong dissection has not taken place. The use of the floating-dot reference mark of many photogrammetric instruments may be especially helpful in tracing a geologic contact from an area where the contact is well expressed to an area where the contact is obscured. Sandstone and shale below the pyroclastic rocks are in large part poorly exposed because of the slope wash that covers the deposits.

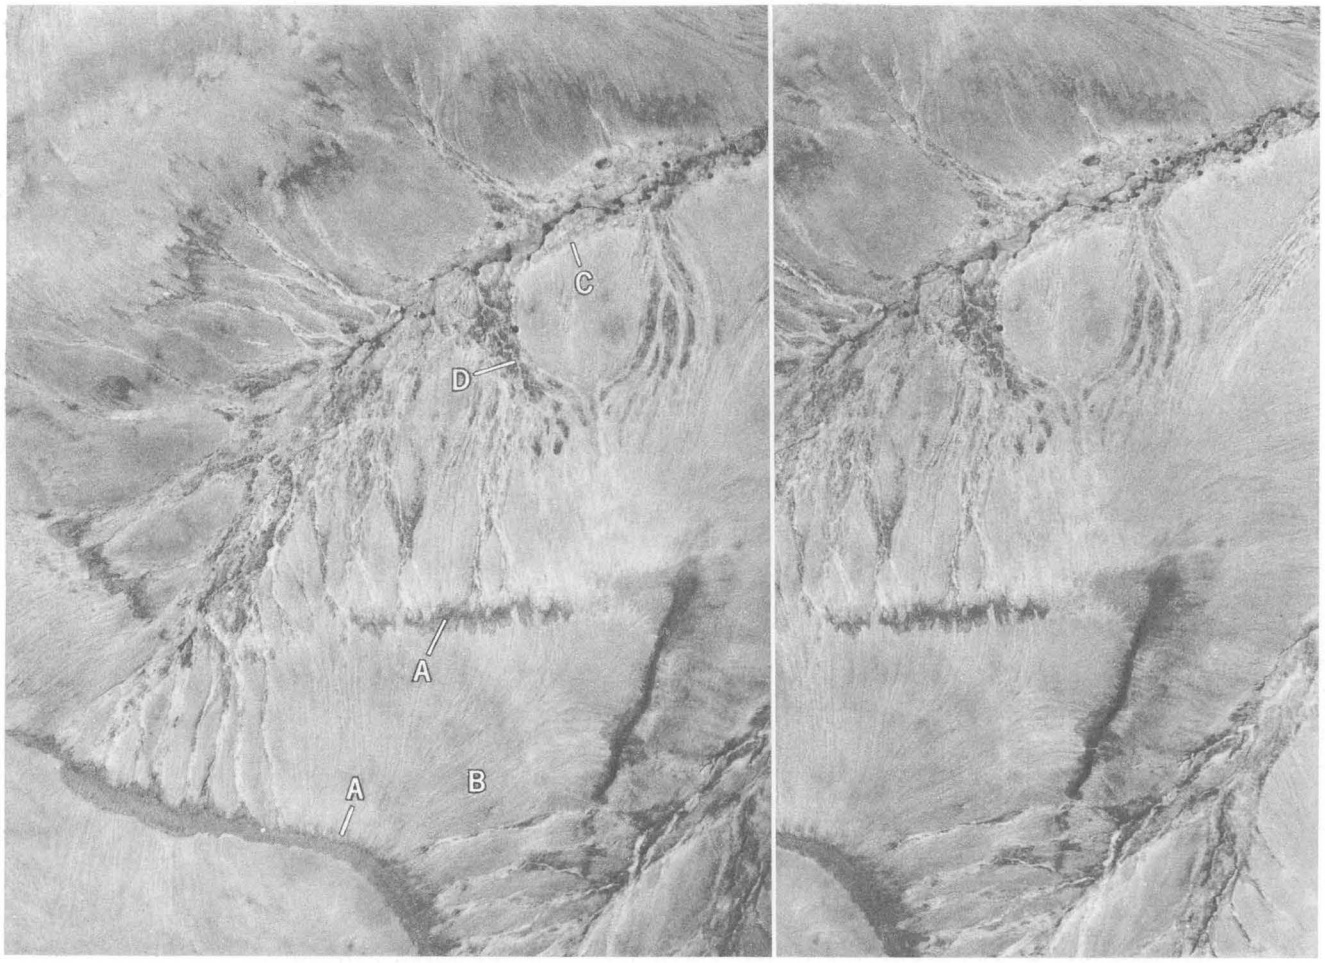

FIGURE 40.—AREA UNDERLAIN PREDOMINANTLY BY GENTLY FOLDED SANDSTONE, SHALE, CONGLOMERATE, AND GRAYWACKE (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

In some areas where outcrops are sparse or lacking bedding may be traced on the basis of topography and vegetation. Resistant beds of sandstone and conglomerate cause small topographic rises, in some areas as little as 2 feet, which are easily discerned in the stereoscopic model because of vertical exaggeration present in viewing most stereoscopic pairs. The steepened slope caused by the resistant bed is commonly populated with a different mossy and grassy vegetation from that of surrounding areas, and bedding is revealed as wide, strongly curved bands of vegetation that are recognized on photographs by their lighter or darker photographic tone than surrounding areas. Such bands of vegetation, as at *A*, are commonly seen clearly on aerial photographs or from a distance on the ground, but are not always readily distinguished when standing directly on them on the ground.

Permafrost is shown by the presence of beaded drainage, indicated by isolated pools of water connected by short, incised watercourses along main stream. Striped slopes, *B*, are typical but not unique to permafrost areas (contrast fig. 53). Note high-center polygons, *C*, that exhibit raised centers surrounded by depressed dark-toned edges. Angular drainage channels, *D*, are related to melting out of ice wedges and are common in permafrost areas.

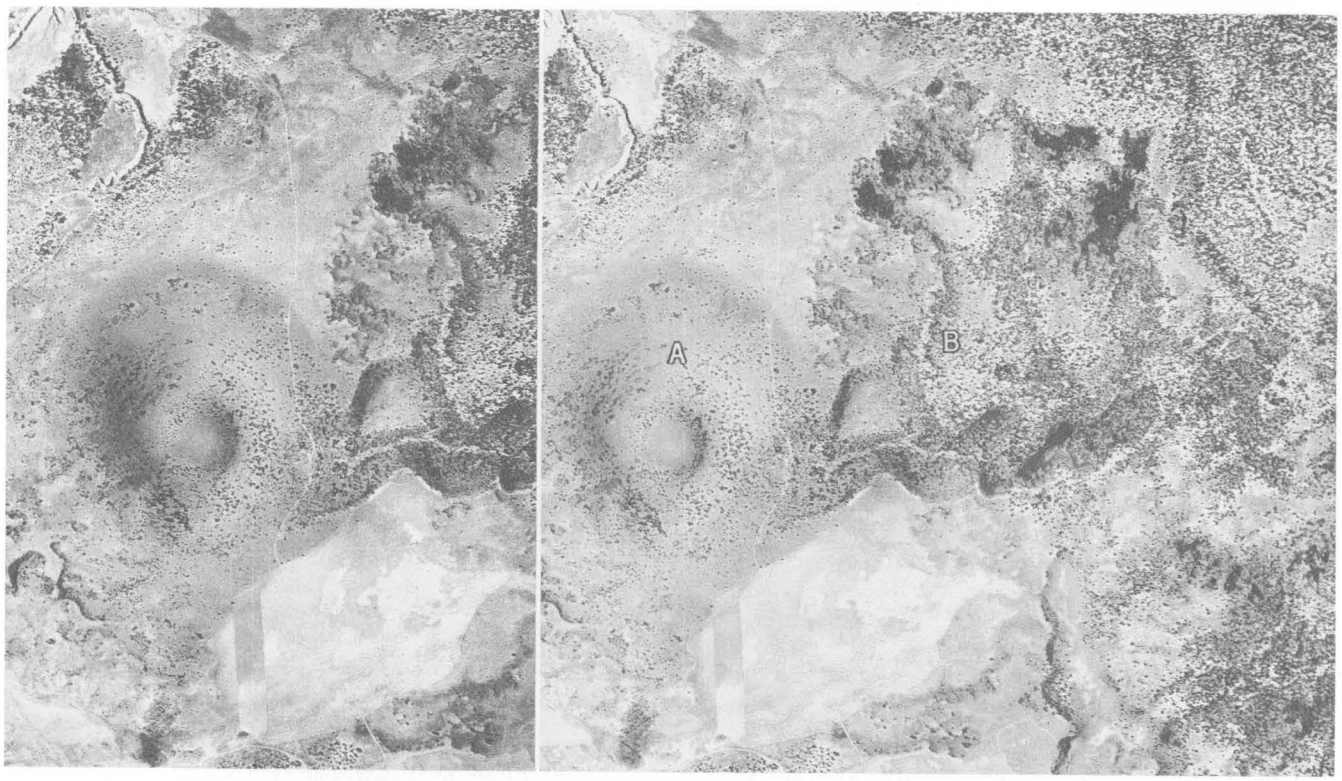

FIGURE 41.—EXTRUSIVE VOLCANIC ROCKS AND ASSOCIATED CINDER CONE (UTAH).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Cinder cone, *A*, is readily identified on the basis of shape of the constructional landform. Associated flows, *B*, are dark toned, irregular in ground plan, and marked by very uneven topographic surfaces. Many lava flows lack surface drainage rills, which suggests permeable material. Note especially the lack of surface drainage channels on flanks of cinder cone.

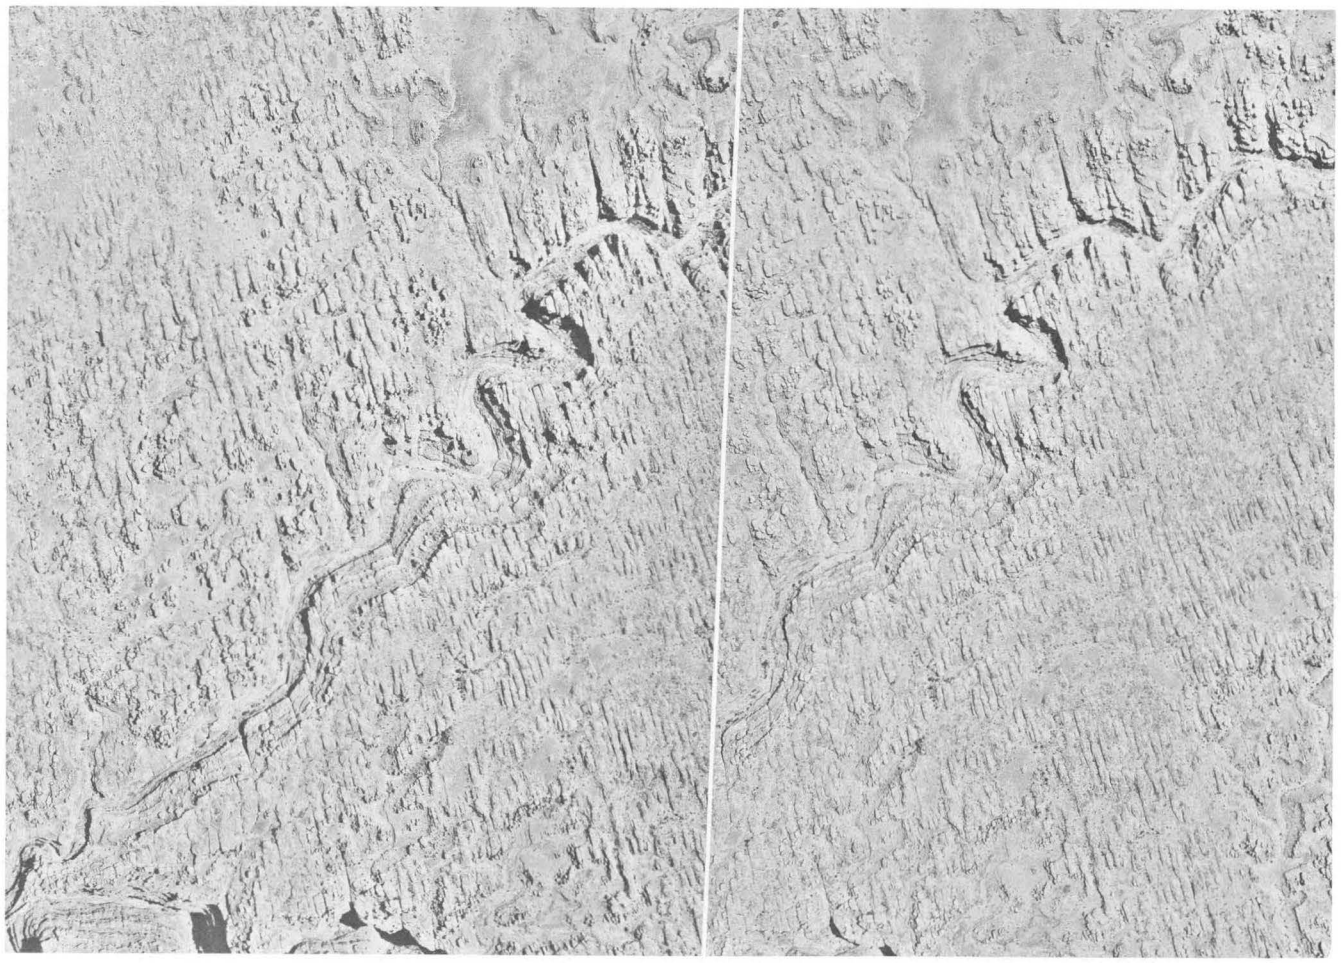

FIGURE 42.—FLAT-LYING SANDSTONE (SOUTHERN UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Prominent wide-spaced joints are shown by many short lineations. Where beds are essentially flat lying, joints commonly form in a right-angle pattern and give the terrain a blocky appearance locally, although one direction of jointing may dominate and give a conspicuous linearity to the topographic grain. The light photographic tone and coarse-textured drainage is typical of coarse sedimentary rocks. Major drainage is dendritic; this pattern is commonly characteristic of flat-lying rocks. Minor drainage is controlled by joints.

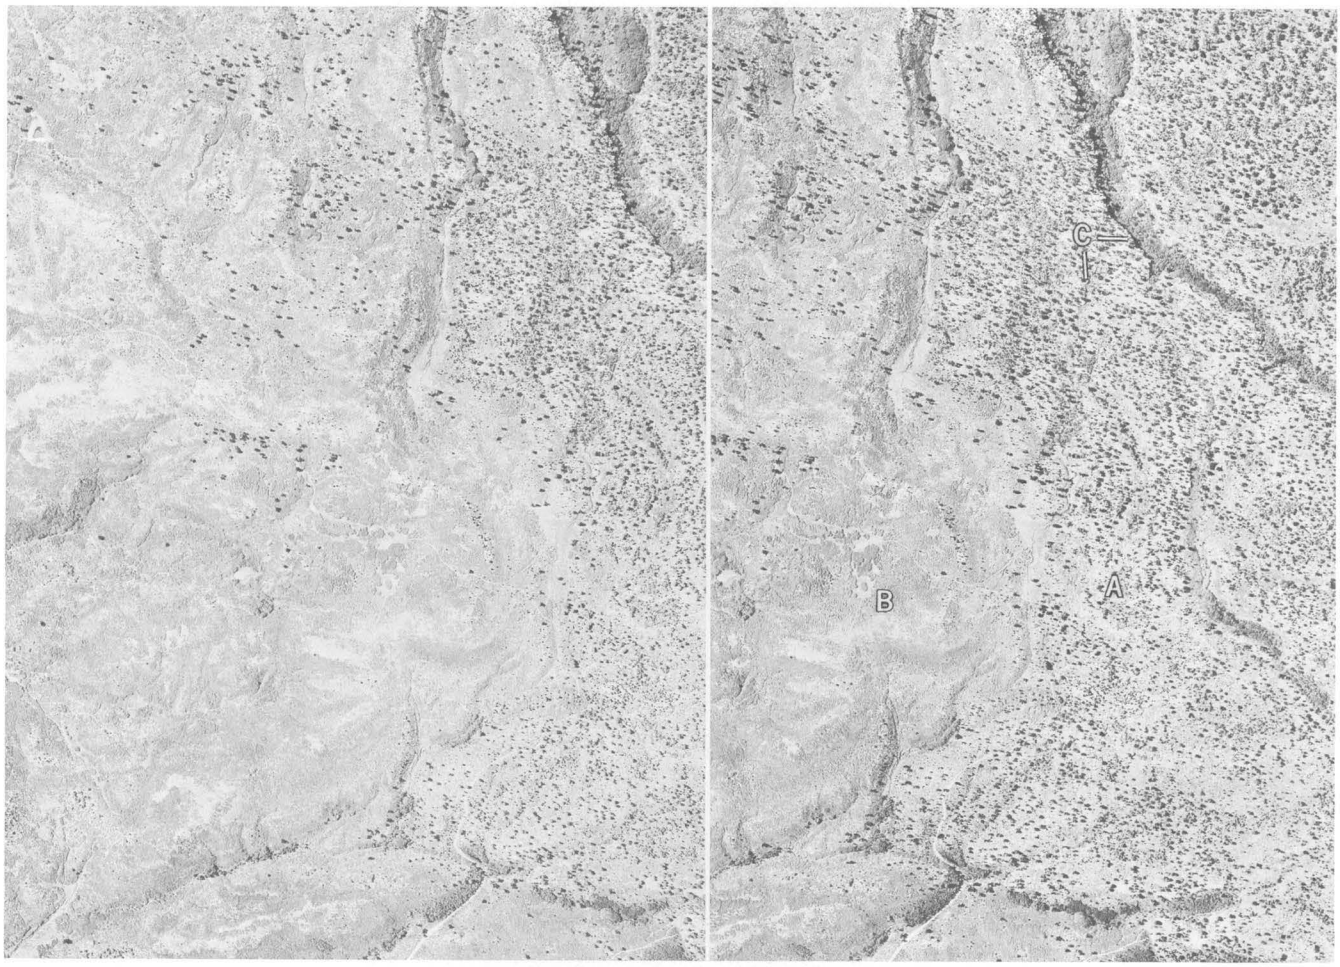

FIGURE 43.—SANDSTONE AND CONGLOMERATE BEDS INTRUDED BY DIORITE PORPHYRY LACCOLITH (UTAH).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Conspicuous contrast in vegetation results from different lithologic types. Sandstone and conglomerate beds, *A*, are covered largely with scattered tall jack, yellow, and ponderosa pine trees. Diorite porphyry, *B*, is covered with scrub oak as much as 10 feet high. This dense growth of scrub oak forms a photographic texture that contrasts with areas covered with pines. Note serrated edges of bluffs, *C*, which are expressions of joints in sandstone and conglomerate beds.

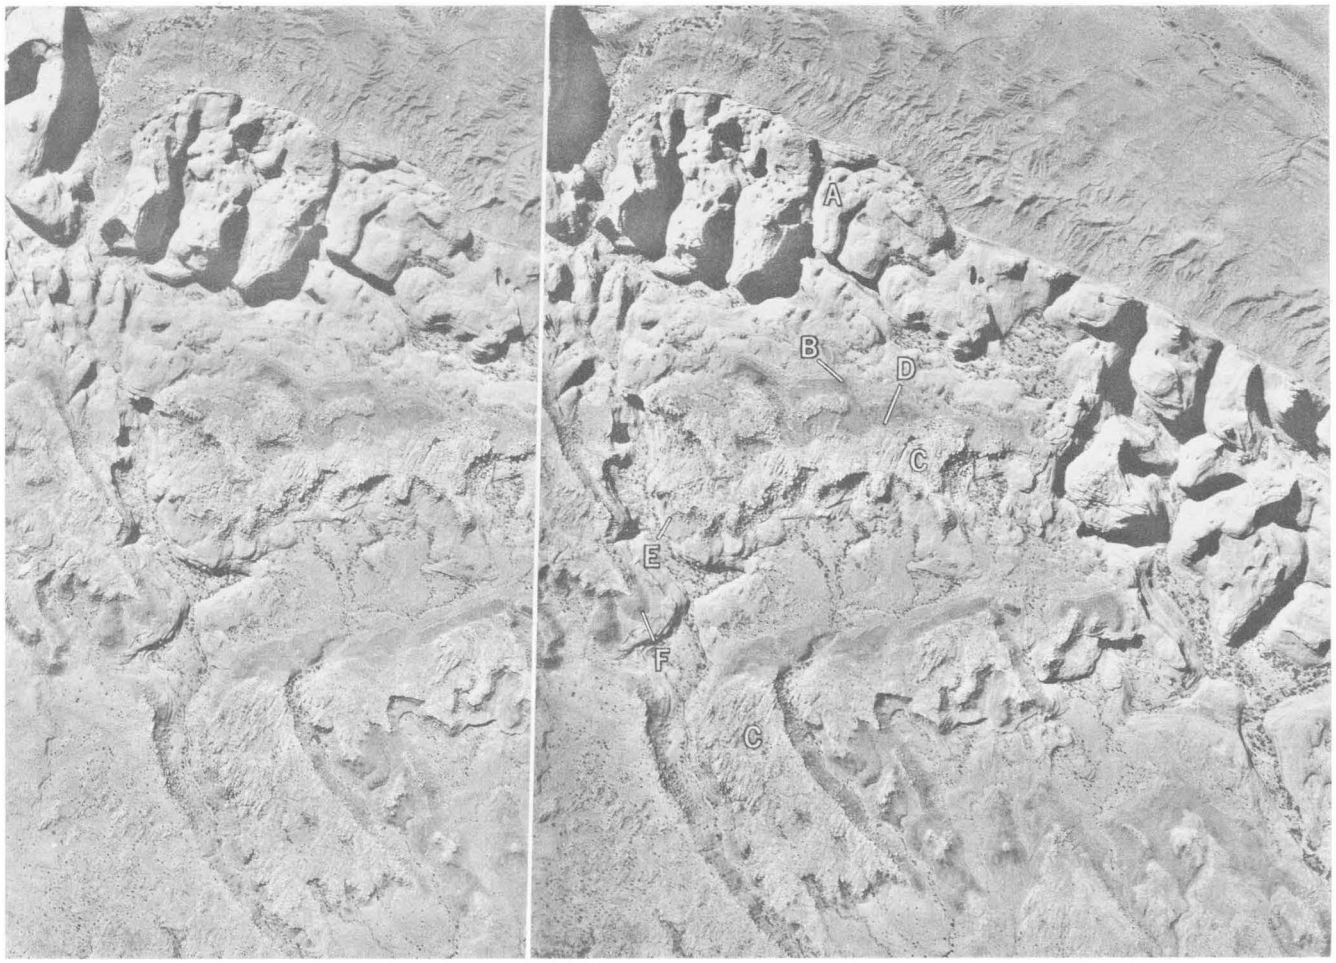

FIGURE 44.—GENTLY DIPPING BEDS OF SANDSTONE, SILTSTONE, AND CONGLOMERATE THAT LOCALLY CONTAIN CHANNEL-FILL DEPOSITS (ARIZONA).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Light photographic tone of rocks, *A*, is typical of massive crossbedded sandstone in this area. Dark-toned rocks, *B*, are reddish thin-bedded shaly siltstone, shale, and fine-grained sandstone. Light-toned conspicuously jointed rocks, *C*, are uranium-bearing sandstone, conglomerate, and mudstone. Locally the dark-toned rocks have been eroded by channel scour, and the channels have been filled with sandstone and conglomerate that now lie unconformably on the older rocks. Erosion of dark-toned rocks along line *D*, which represents the line of unconformity and orientation of a channel in this area, is conspicuous by the photographic tone change. At *E* the dark-toned rocks have been completely eroded away and light-toned jointed sandstone and conglomerate rest on the light-toned massive crossbedded sandstone. At *F* the dark-toned rocks again become conspicuous where overlying rocks thin. Differences in stratigraphic thicknesses of the dark-toned rocks, which reflect a thickening of overlying rocks that were deposited in old river channels, can be measured photogrammetrically. Isopach lines may be drawn to indicate the orientation of the channel and the general depth of the channel.

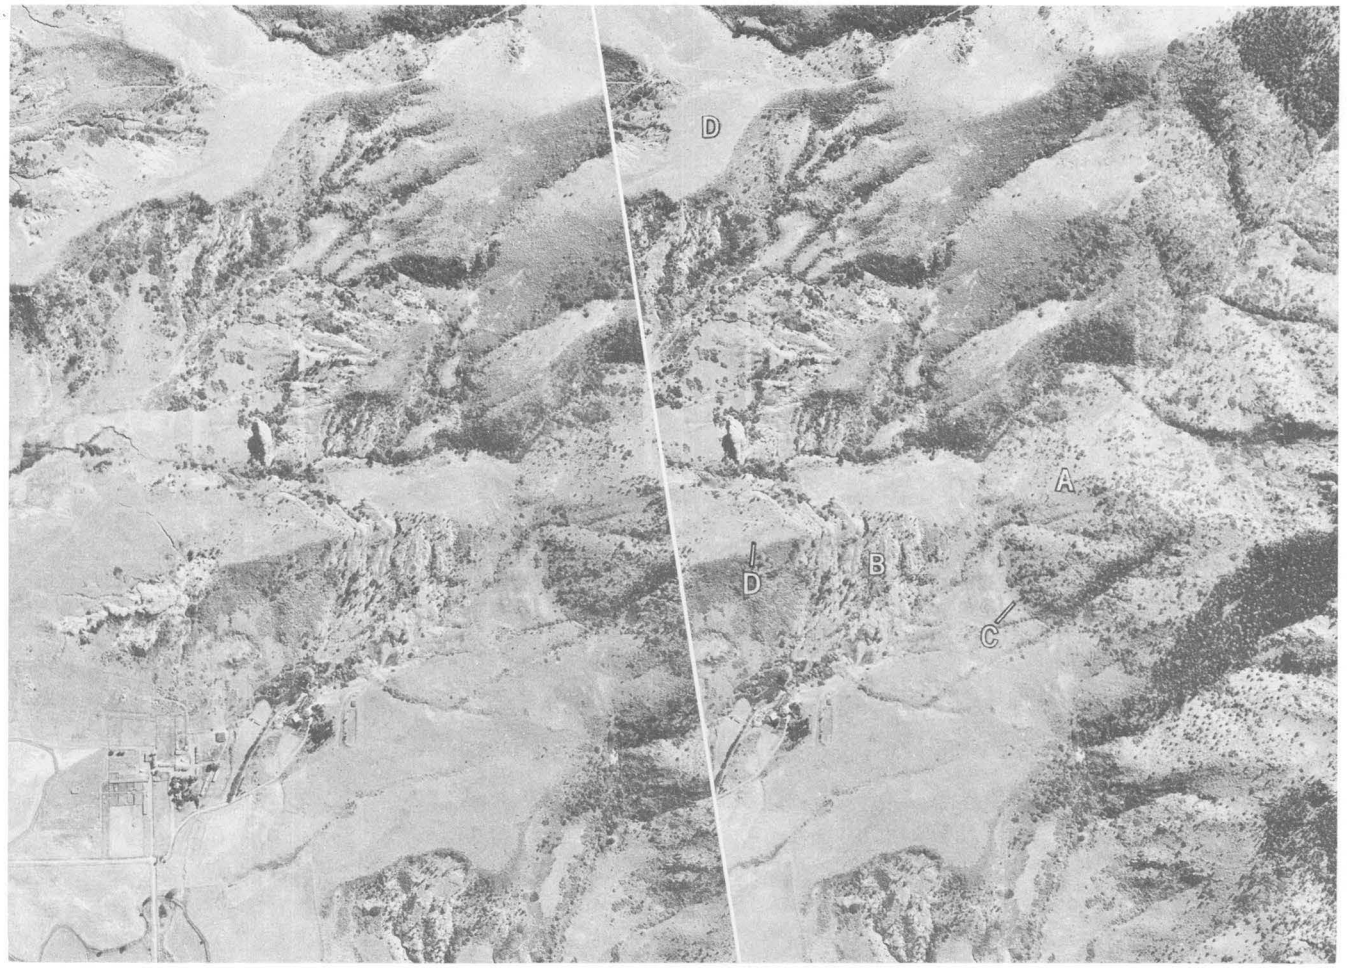

FIGURE 45.—GNEISS, SCHIST, AND GRANITE FLANKED BY DIPPING SEDIMENTARY ROCKS TRUNCATED BY PEDIMENT GRAVEL (COLORADO).

[Approximate scale 1 : 21,000. Photographs by U.S. Air Force]

Topographically high, vegetated area, *A*, is underlain by gneiss, schist, and granite. Light-toned sedimentary rocks, *B*, lying unconformably on the igneous and metamorphic rocks, are primarily arkose and sandstone. Trace of unconformity between sedimentary rocks and igneous and metamorphic rocks is indicated by break in slope, *C*, which is locally accentuated by contrast of trees on steep slope uphill from the trace of the unconformity with grassy vegetation on the gentler slope below. Note effect on dip of vertical exaggeration in the stereoscopic model. The arkose and sandstone unit dips about 25°. The grass-covered pediment gravel, *D*, which truncates the underlying sedimentary rocks, dips 2° to 3°.

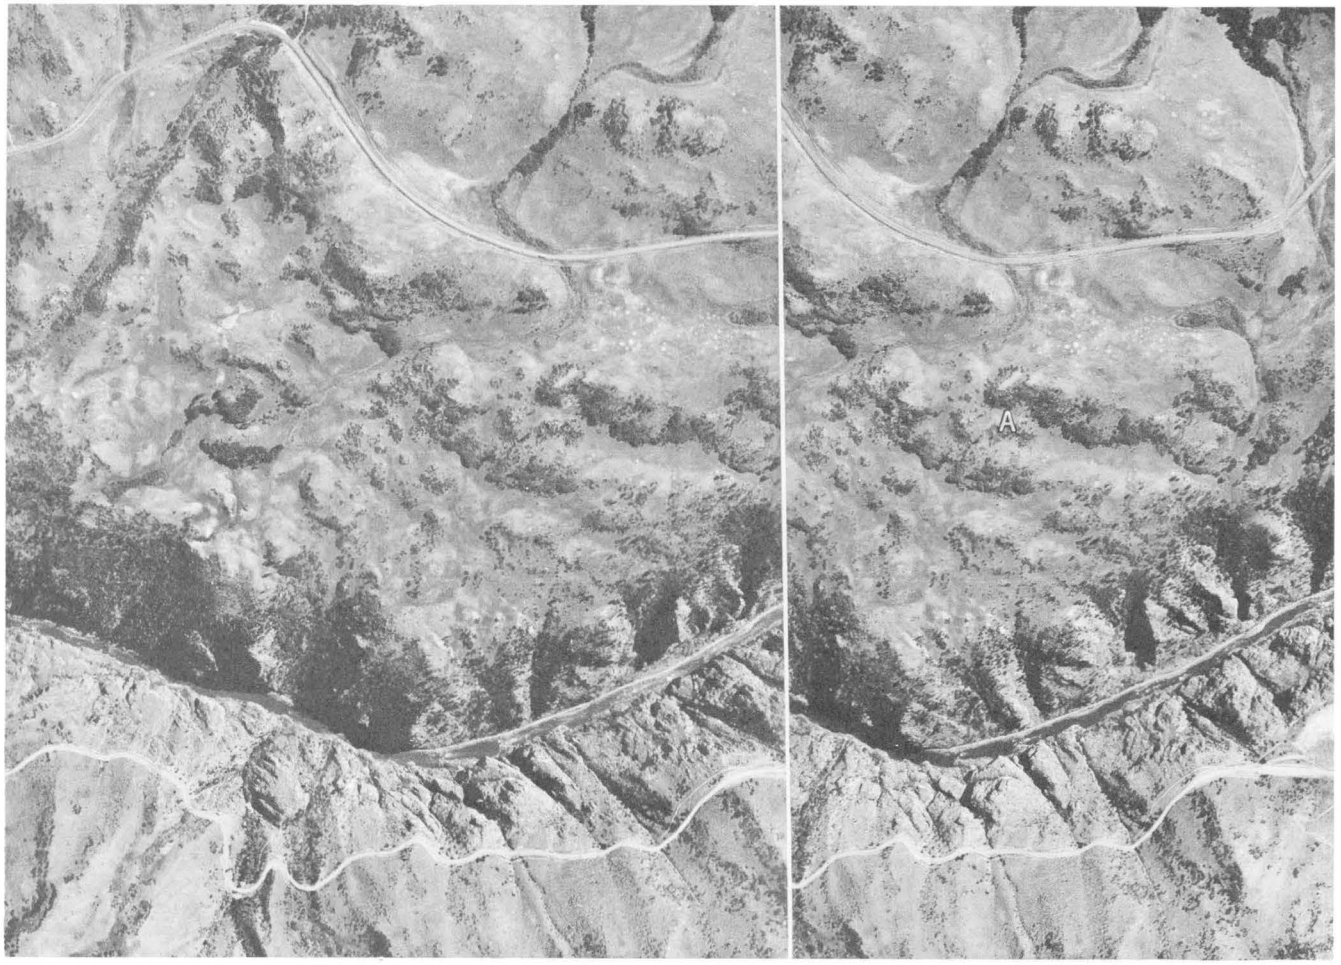

FIGURE 46.—LANDSLIDE AREA (COLORADO).

[Approximate scale 1 : 37,000. Photographs by U.S. Geological Survey]

Landslides are indicated primarily by landform. Note the characteristic hummocky topography of slide material prominent at *A*. Minor ridges of the slide area are commonly parallel to the contour of the slope; clumps of vegetation locally are oriented parallel to the contour of the slope also. Poorly resistant sedimentary rocks underlie the landslide debris; resistant volcanic flows (not shown) cap the sedimentary rocks. In many areas where poorly resistant rocks underlie a resistant caprock, conditions for landsliding are favorable. Highly fractured rocks in canyon are schist and gneiss.

FIGURE 47.—ORTHOPHOTOGRAPH AND PERSPECTIVE PHOTOGRAPH OF SAME AREA.

(Left) Part of perspective aerial photograph showing distortions in powerline caused by relief displacement of image points. (Right) Orthophotograph of the same area showing that relief displacement has been eliminated in preparing orthophotograph. Note that the powerline is straight.

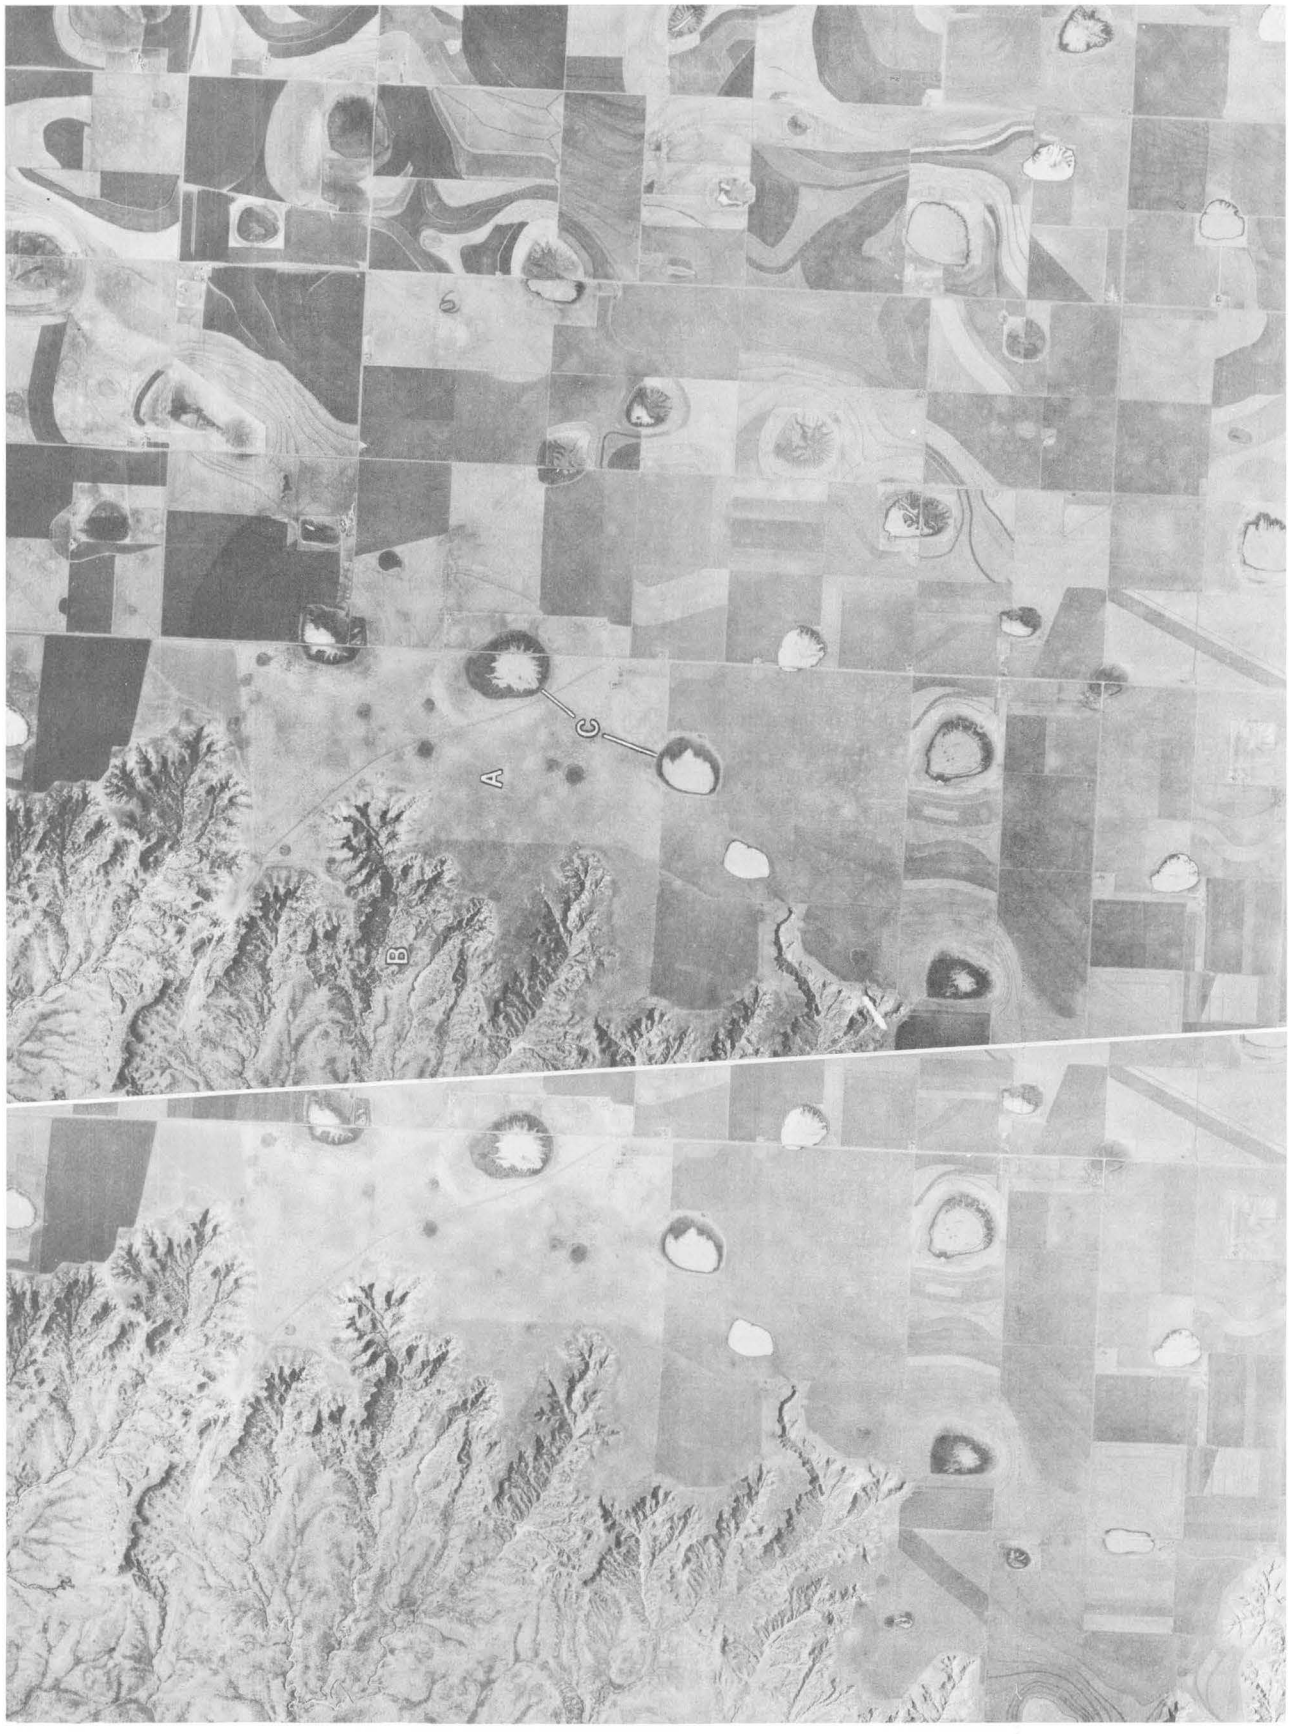
FIGURE 48.—AREA SHOWING RELATION OF PHOTOGRAPHIC TONE, LAND-USE PATTERN, AND DRAINAGE TO RESIDUAL SOIL, ROCK TYPE, AND GEOLOGIC STRUCTURE (SOUTH CAROLINA).

[Approximate scale 1 : 60,000. Photographs by Army Map Service]

Aerial photographs commonly show an association of features that is meaningful to the interpreter. Here photographic tones, land-use pattern, and drainage pattern are associated with specific soils, rock types, and geologic structure. Note that the small scale of the photographs is a significant factor in showing the striking land-use pattern and drainage pattern (see also fig. 4). The circular land-use pattern of the farmed area generally bounded by vegetated areas, as at *A*, represents soils developed on underlying mafic rocks. Rocks in the immediately surrounding vegetated areas are largely silicic intrusive types. The drainage characteristics of the area also suggest a pluglike or domal geologic structure. Streams at *B* and *C* form a conspicuous annular pattern around the area of mafic rocks and probably mark the contact of the mafic rock body.



Stereoscopic pair

Approximately 1 mile

FIGURE 49.—SHALE AND THIN SANDSTONE INTERBEDS CAPPED BY POORLY CONSOLIDATED GRAVEL AND SAND, LOCALLY CEMENTED WITH CALCAREOUS MATERIAL (TEXAS).

[Approximate scale 1 : 63,360. Photographs by Army Map Service]

Lack of surface drainage at *A* indicates high degree of permeability in capping material. Note in contrast the striking fine-textured drainage on the relatively impermeable shale area, *B*. Broad depressions, *C*, in capping gravel and sand are very shallow and show little relief even with vertical exaggeration found in the stereoscopic model. These depressions resulted in large part from wind action; some solution of local calcareous cementing material also may have taken place. Dark areas within depressions represent a darker vegetation growth; light-toned areas represent in part washed-in fine materials that were dry and hence light colored at the time the photographs were taken. Locally some light-toned evaporite deposits may be present.

FIGURE 50.—RECENTLY FAULTED STRAND LINES OF FORMER LAKE (NEVADA).

[Approximate scale 1 : 20,000. Photographs by Soil Conservation Service]

Strand lines of beach sand, *A*, are shown strikingly by dark photographic tone and slightly higher altitudes than surrounding surficial material. Note that strand lines are truncated by a recent fault, *B*, shown by narrow band of dark vegetation and by low scarp. Drainage density is relatively high on the thin alluvial cover, *C*, but decreases noticeably on opposite side, *D*, of fault where better drained, thicker deposits of alluvial material are present. Strand line is faulted up about 25 feet at *E* by recent fault movement. An irregular fault trace is also seen at *F*.

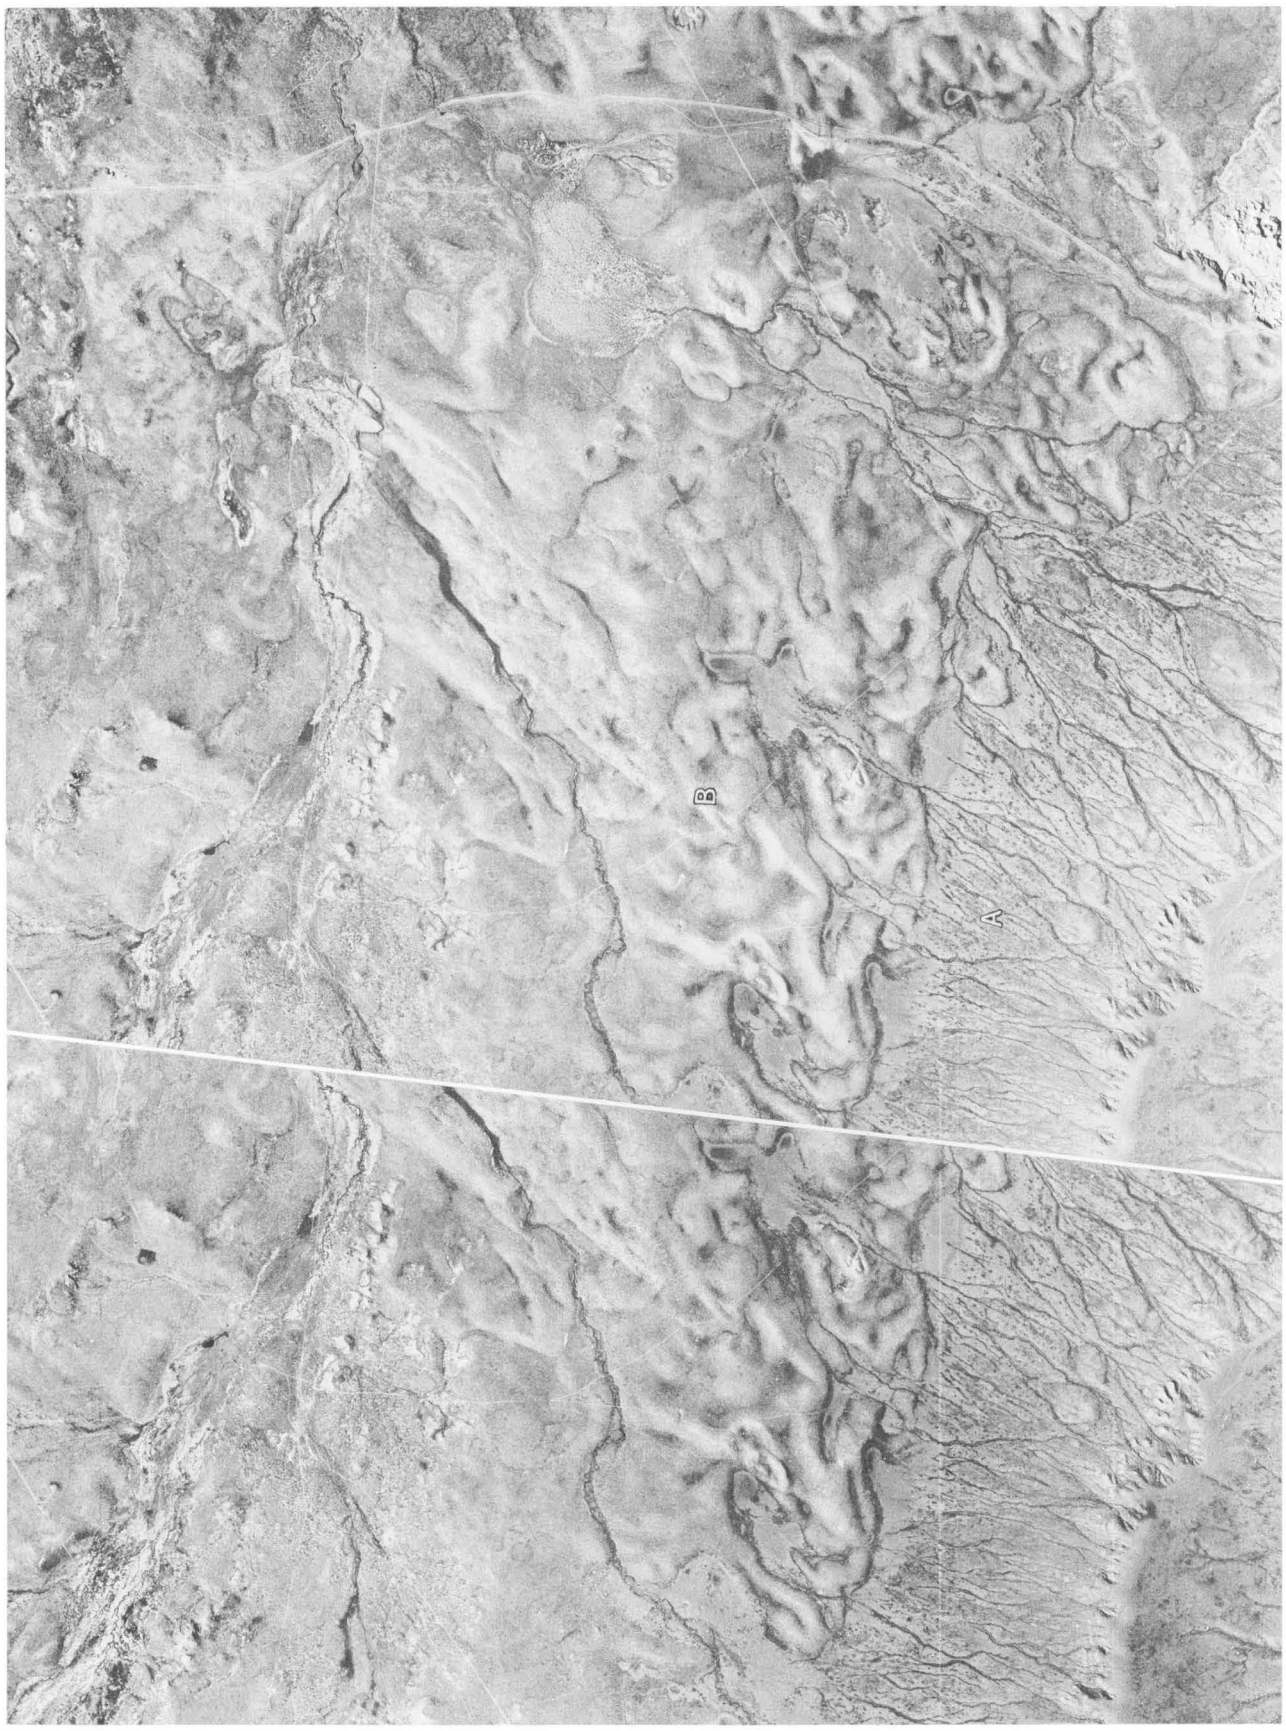
Approximately 1 mile

FIGURE 51.—STEEPLY DIPPING SEDIMENTARY ROCKS INTRUDED BY QUARTZ DIORITE (CALIFORNIA).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Generally massive dark-toned conglomerate sequence, *A*, exhibits coarse-textured drainage and erosional characteristics, whereas fine-grained weakly foliated quartz diorite, *B*, has a fine-textured drainage and erosional topography. Widely spaced joints, conspicuous in many intrusive masses, are not present in the quartz diorite. Dendritic drainage in the conglomerate sequence is not typical of most dipping sedimentary rocks; the dendritic drainage pattern suggests a massive character and uniformity of the conglomerate sequence and general lack of bedding which might control the drainage. Local light-toned interbeds, *C*, indicate strike and dip of the sedimentary rock sequence.



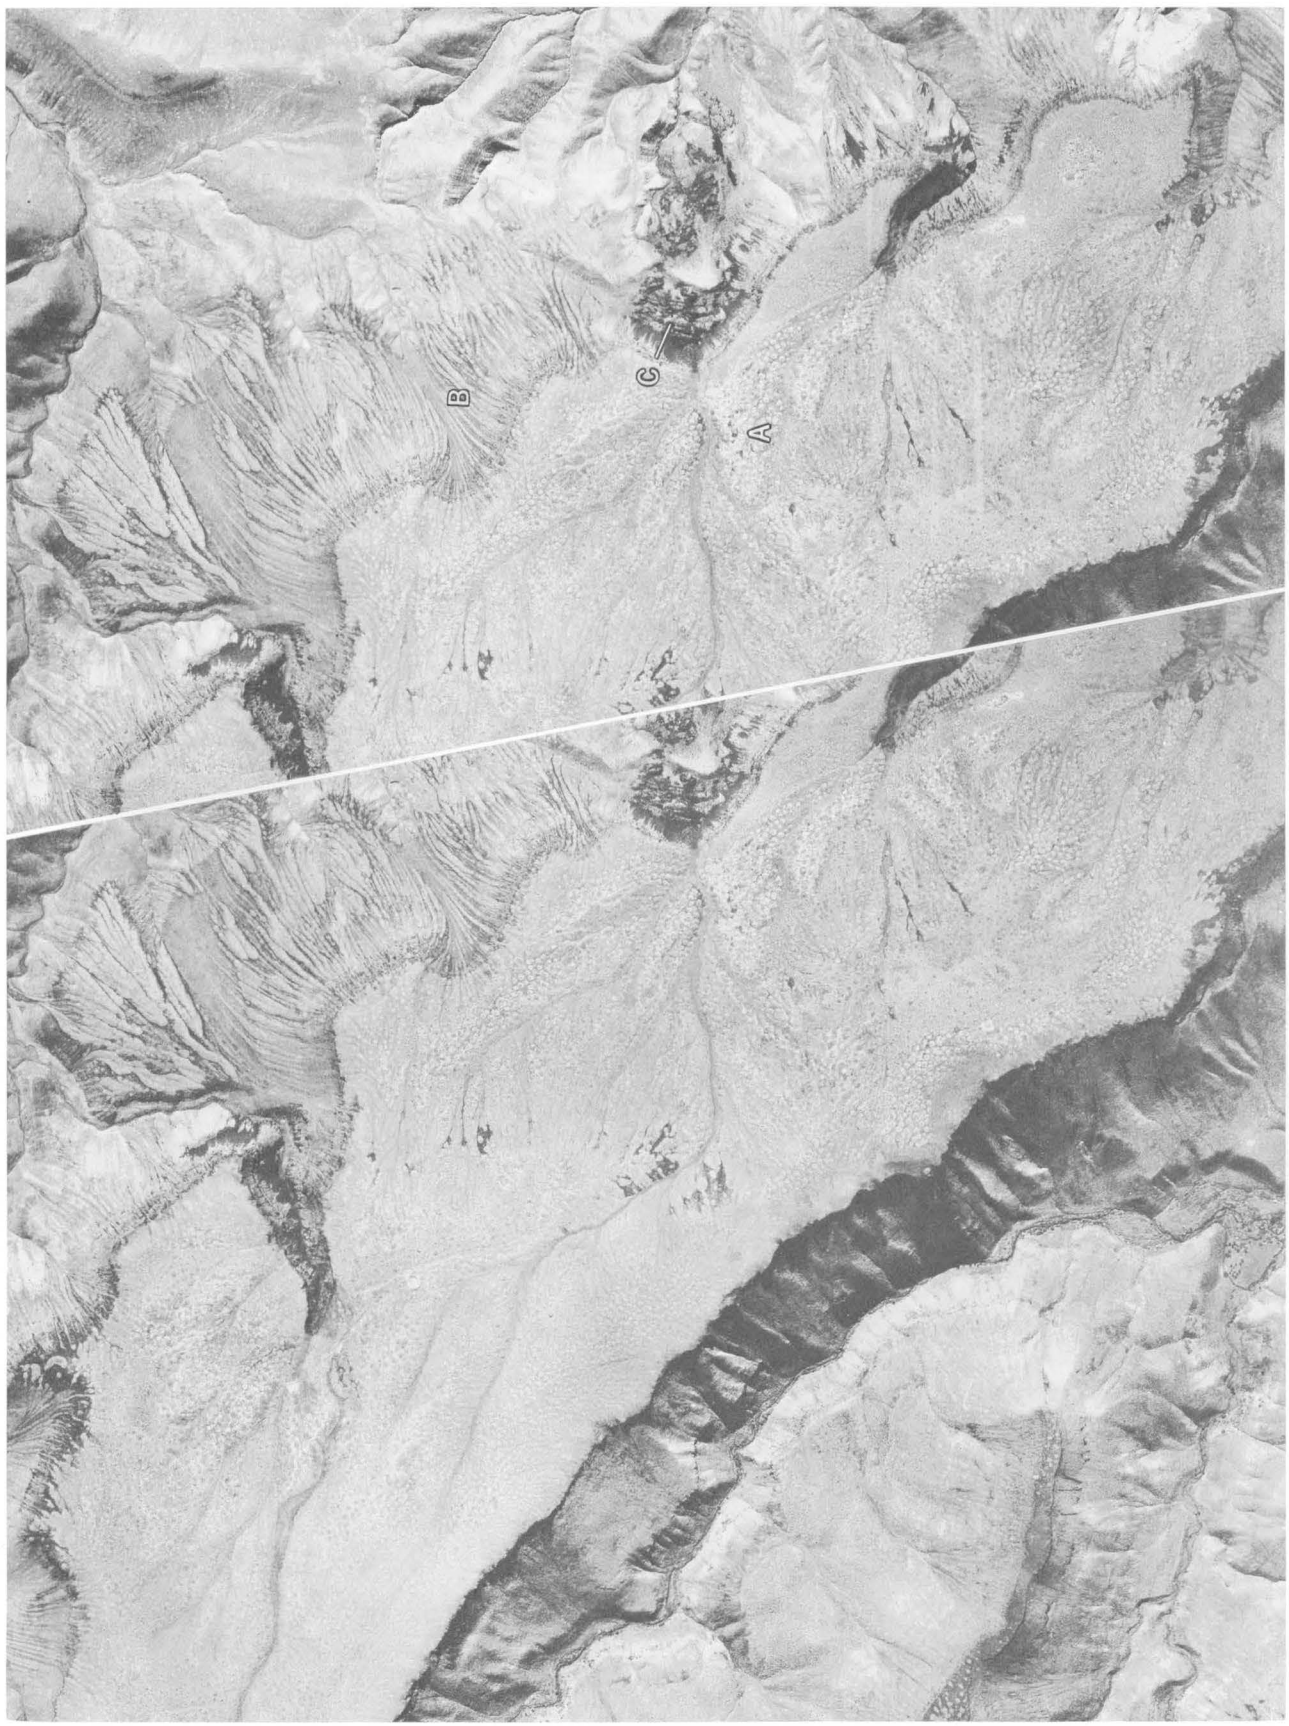
Stereoscopic pair

Approximately 1 mile

FIGURE 52.—AREA SHOWING DRAINAGE CHARACTERISTICS IN SURFICIAL MATERIALS (WYOMING).

[Approximate scale 1 : 28,000. Photographs by U.S. Geological Survey]

Strong contrast in drainage densities of areas *A* and *B* reflect differences in underlying materials. Fine-grained surficial sedimentary deposits, *A*, that form a thin cover on impermeable shale here exhibit fine-textured drainage. The many drainage rills flowing across the fine-grained surficial material disappear into sand dune area, *B*, which is composed of granular material of high permeability. Although partly stabilized and covered by vegetation the sand dunes locally show barchan shapes, which aid in their identification.



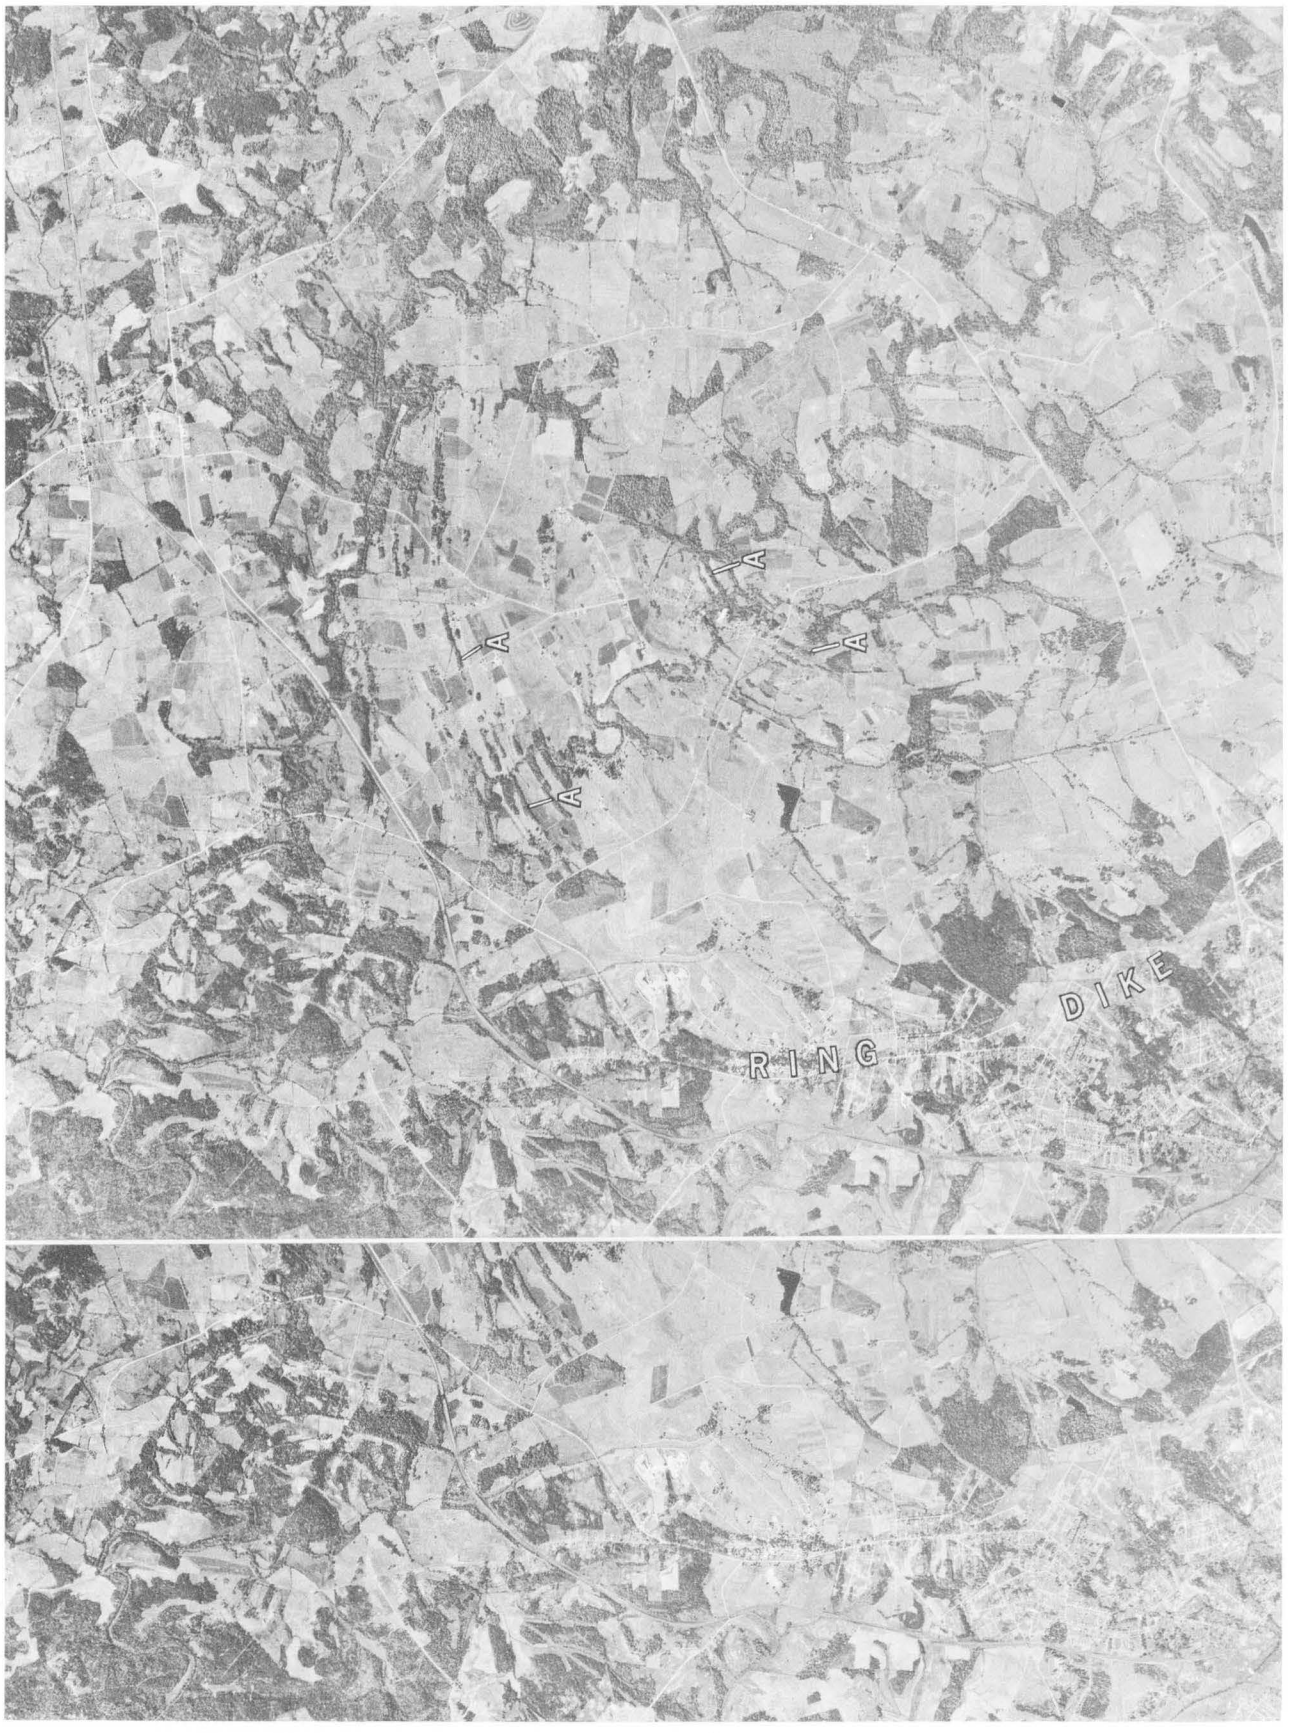
Stereoscopic pair

Approximately 1 mile

FIGURE 53.—AREA OF BASALT FLOWS (IDAHO).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Conspicuous "snakeskin" pattern is commonly found on the undissected basalt flows, *A*; it is not observed on other rock types in this area. The pattern consists of white or light-toned spots scattered in a dark field. Note that a rounded "shape" is a distinctive part of the pattern. The light-toned rounded areas are mounds of clay and silt 20 feet or more across and 2 or 3 feet high. Grass grows on these areas and causes the light photographic tone; the basalt is typically barren or covered with sagebrush and has a dark photographic tone. The striped pattern of closely spaced drainage rills, *B*, is also typical of basalt talus slopes in this area; however, similar-appearing stripes are found on a variety of rock types in other areas (see fig. 40). Where basalt cappings are underlain by poorly resistant rocks, conditions are favorable for landslides, as at *C*.



Stereoscopic pair

Approximately 1 mile

FIGURE 54.—RING-DIKE AREA (NORTH CAROLINA).

[Approximate scale 1 : 58,000. Photographs by Army Map Service]

Ring dike about 1 mile wide and an area of gabbro-diorite within the ring dike can be differentiated from surrounding areas primarily on the basis of the lesser tree coverage and greater land use within the ring-dike area. A ring structure is also suggested by the concentric pattern of trees, *A*, which may reflect structure within the igneous rocks. The contact of syenite of the ring dike and gabbro-diorite of surrounding areas cannot be identified in the stereoscopic model, and aerial photographs of this terrain serve primarily to differentiate anomalous features which then must be examined in the field. Note excavation in syenite of the ring dike.

FIGURE 55.—AREA IN MAINE SHOWING ESKER LANDFORM ON PHOTOGRAPHS OF TWO DIFFERENT SCALES.

[*A:* Approximate scale 1 : 70,000. Photographs by Army Map Service]
[*B:* Approximate scale 1 : 44,000. Photographs by U.S. Geological Survey]

The serpentine shape in plan view and local topographic relief of the esker are readily distinguished in the stereoscopic view of figure *A*. The esker ridge is discontinuous, but the various segments are clearly part of the same ridge. The association of isolated ridge segments is readily made when small-scale photographs showing a large area are viewed. Landform is the primary recognition feature of esker ridges. In figure *B* the esker landform is not as readily identified as in figure *A*, and on commonly available 1:20,000-scale photographs the serpentine shape would probably not be seen in any one stereoscopic model. Esker sands and gravels are commonly well drained and are a source of borrow material for the construction engineer. Note old secondary road, *a*, built along the top of the esker, probably because of good subgrade and drainage.

Approximately 1 mile

FIGURE 56.—STABILIZED SAND DUNES (CENTRAL ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Air Force]

Strong contrasts in photographic tone and photographic texture mark sand dunes and interdune areas. Dunes, as at *A*, are now stabilized and covered with trees. Coarse well-drained sands of the dunes support dark-toned black spruce. Light-toned interdune areas of frozen silt support grasses. Lakes were formed on the original glacial outwash plain, which was the source of sand for dune formation. The shape of the dune landform is an important aid to recognition, and the association of trees is significant in the interpretation of the soils and ground conditions. Relief of the dunes is vertically exaggerated in the stereoscopic model.

Approximately 1 mile

FIGURE 57.—MORAINAL DEPOSITS OF TWO GLACIATIONS (CENTRAL ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Air Force]

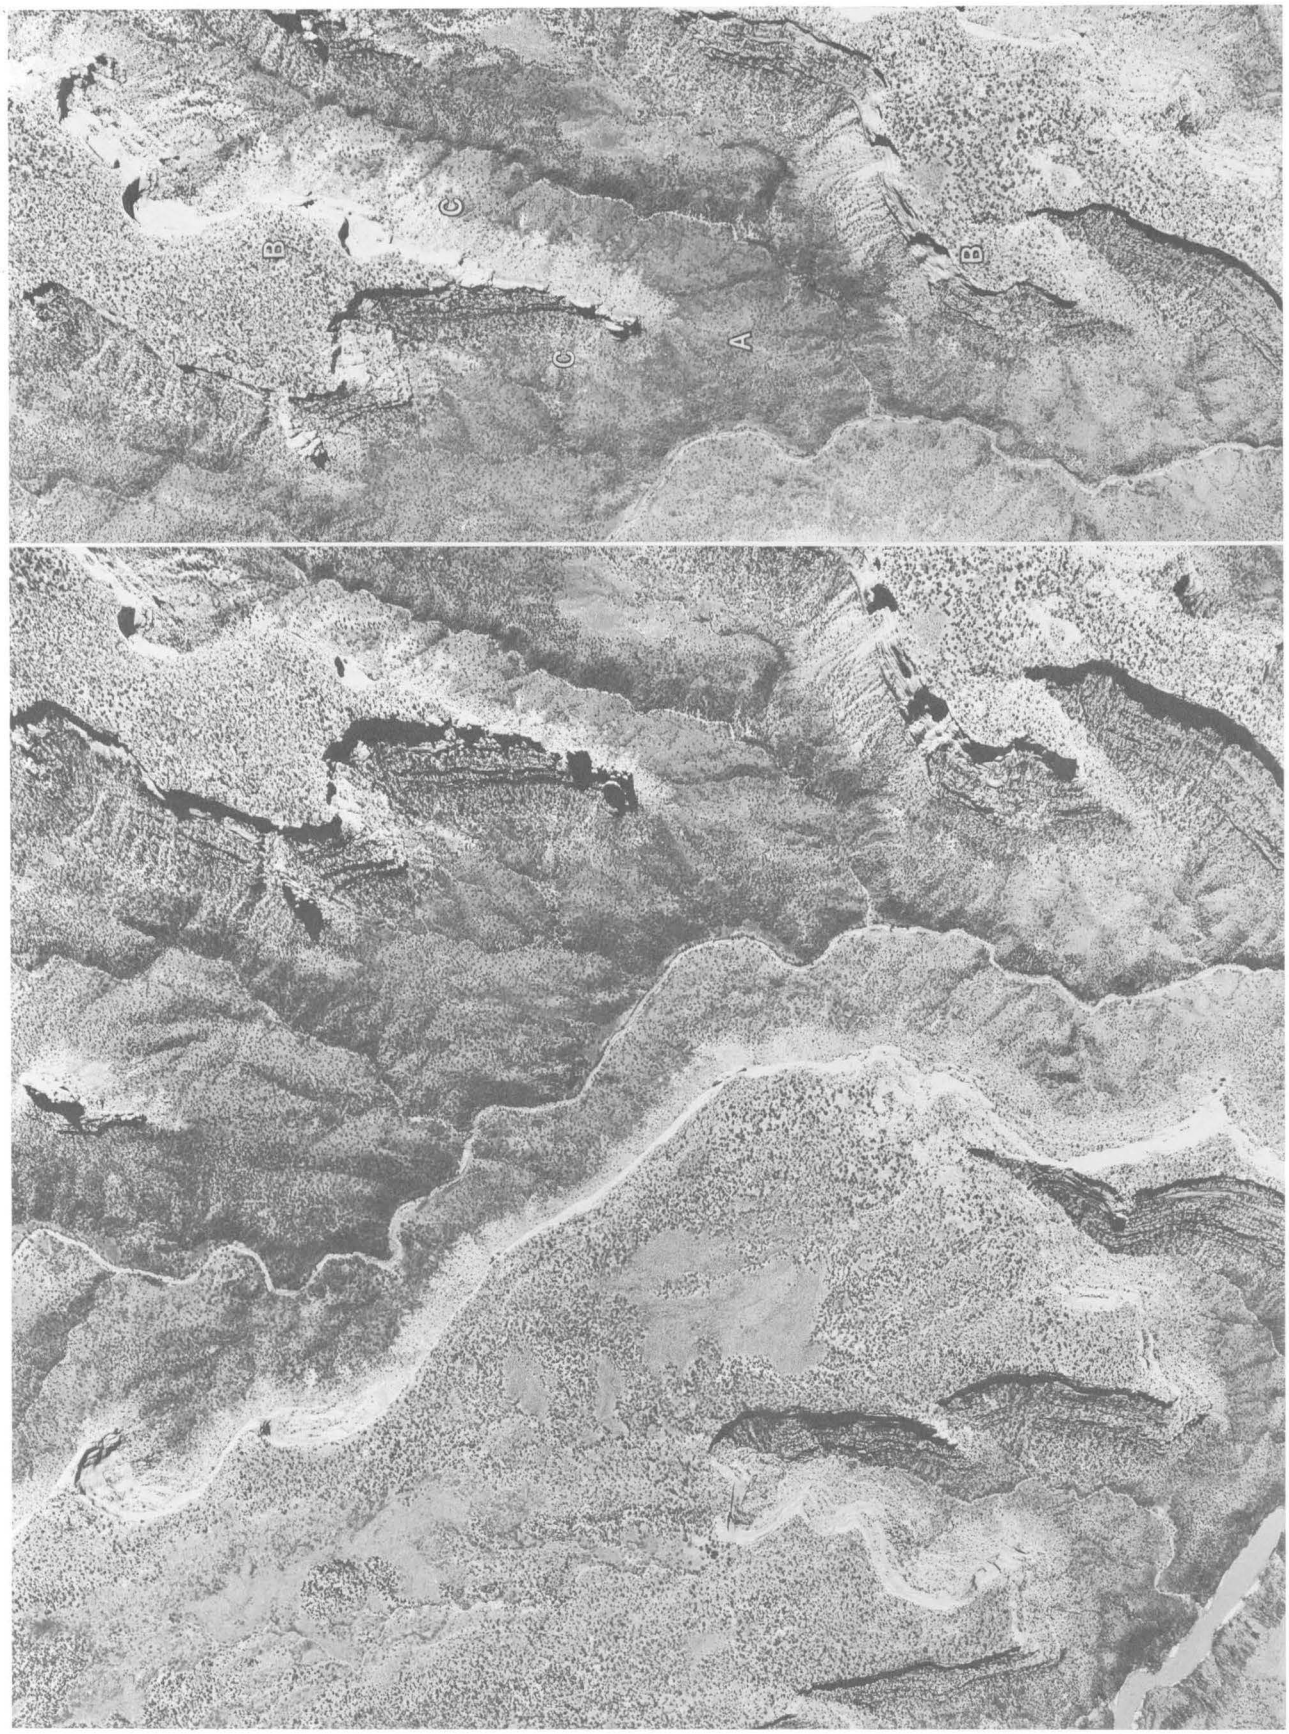
Arcuate plan-view shape of terminal moraine, *A*, is marked by a lighter photographic tone than that of the surrounding area. This moraine is characterized by an abundance of small undrained lakes and ponds and by poorly integrated drainage. In older terminal moraine, *B*, lakes and ponds are largely drained, but arcuate plan of this moraine is still preserved. Terminal moraine, *C*, represents an advance only slightly younger than *A*. Note similarity of topographic expression and development of ponds and lakes in moraines *A* and *C*.

Stereoscopic pair
Approximately 1 mile

FIGURE 58.—MORAINAL DEPOSITS OF CONTINENTAL GLACIATION (SOUTH DAKOTA).

[Approximate scale 1 : 60,000. Photographs by Army Map Service]

Terminal moraine, *A*, contains generally few lakes and ponds in contrast with older ground moraine, *B*, in which water-filled kettle holes are numerous. Arcuate plan-view shape and higher relief than surrounding ground moraine are typical of the terminal moraine. Note drainage rills developed on parts of topographically high terminal moraine, but general lack of well-developed surface drainage in ground-moraine areas. Ponding also indicates poor drainage in this area. Linear trends parallel to arcuate border of terminal moraine—which represent depositional and erosional characteristics—are similar to some linear trends indicative of faults in other areas.



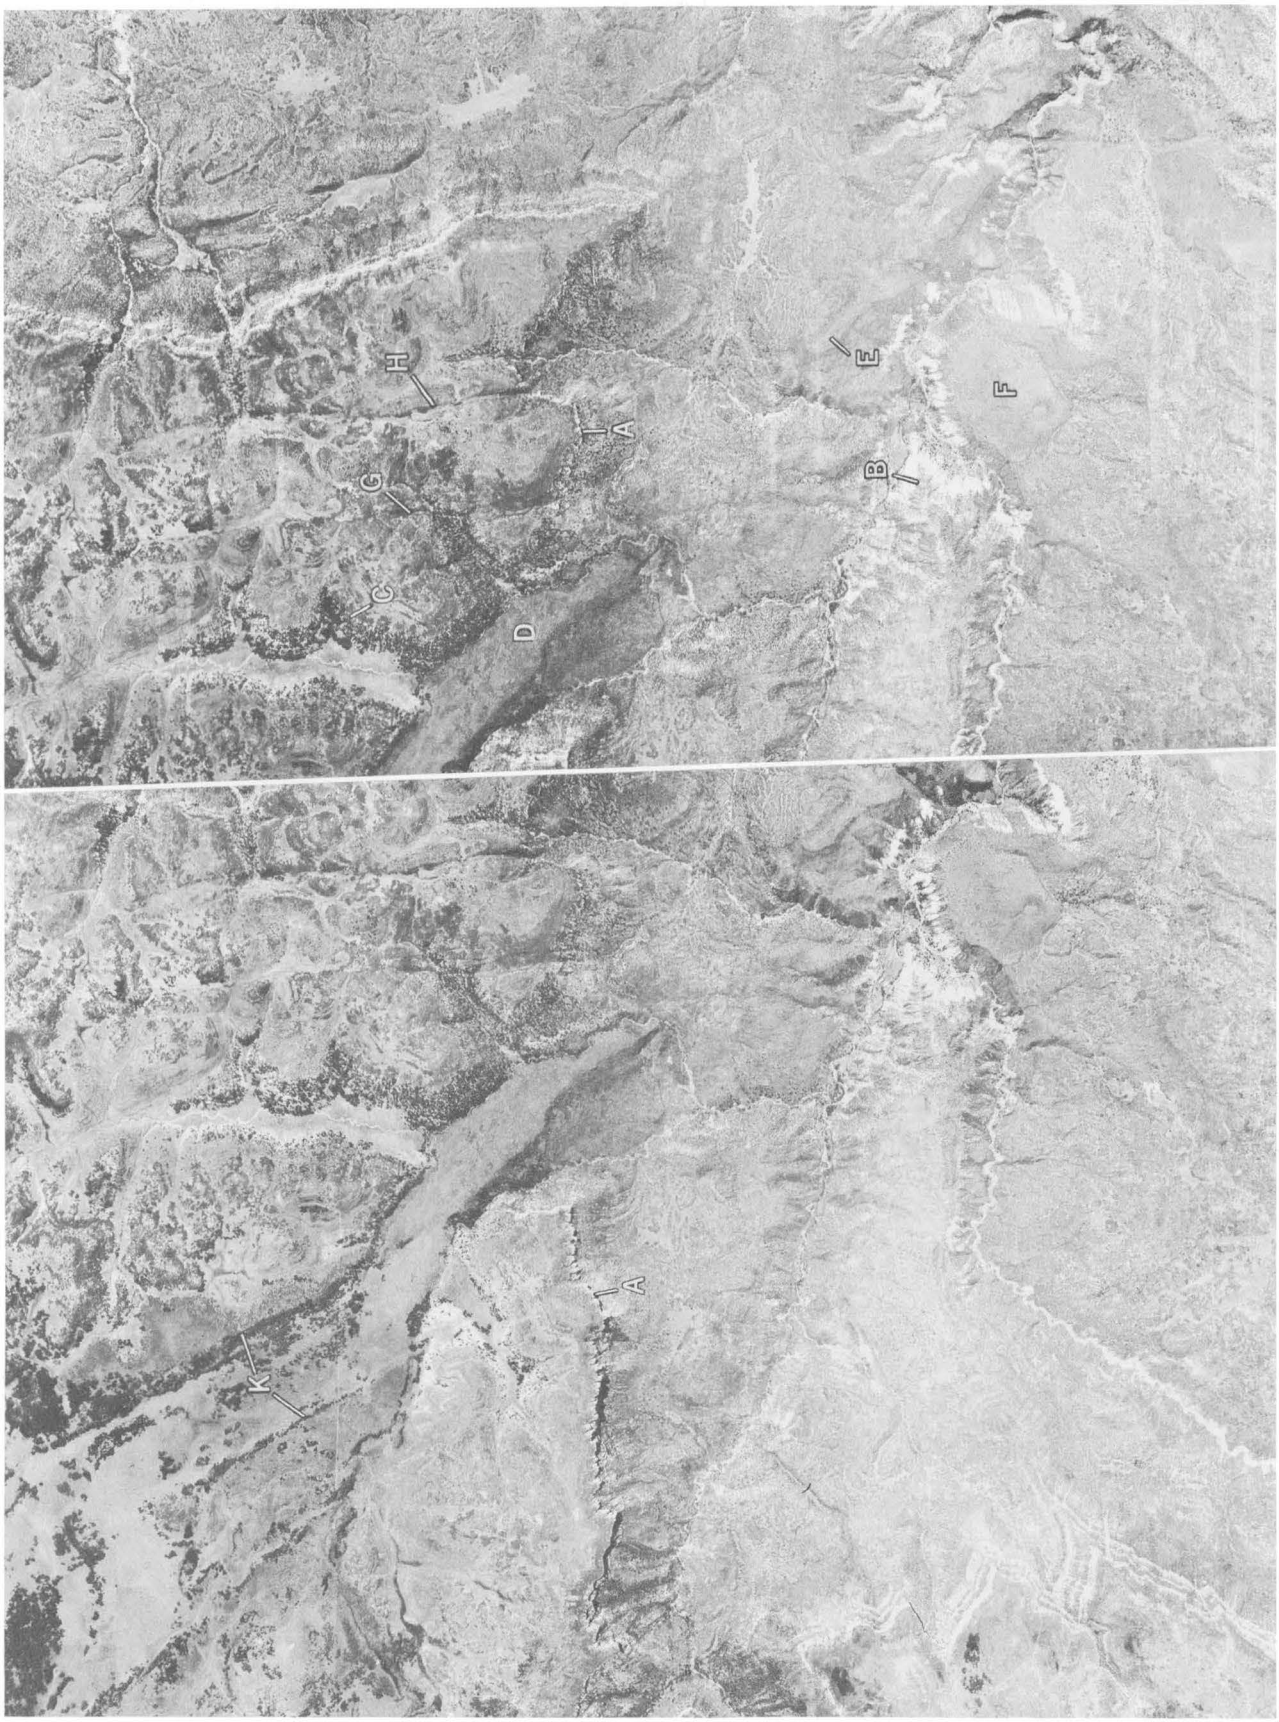
Stereoscopic pair

Approximately 1 mile

FIGURE 59.—GENTLY DIPPING SEDIMENTARY ROCKS LYING UNCONFORMABLY ON GNEISS-GRANITE-SCHIST COMPLEX (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Strong photographic tone differences mark the gneiss-granite-schist area, *A*, and the sedimentary rocks, *B*. Relatively even dip-slope surfaces of sedimentary rocks contrast strongly with hummocky erosional topography of underlying crystalline rocks. The fine-textured dendritic drainage on the crystalline rocks stands out, although such fine-textured drainage is not necessarily diagnostic or typical of igneous and metamorphic areas. The gneiss-granite-schist area shows no bedding, but bedding is marked in the overlying sedimentary rocks by topographic breaks in slope. Light photographic tone and vertical cliffs are characteristic of thick sandstone formation in this area. Large talus blocks, at base of slope, *C*, indicate massive and resistant character of overlying rocks. Shale and silty shale unit below sandstone has a lesser angle of slope, but this slope is masked in part by debris from overlying sandstone.



Stereoscopic pair

Approximately 1 mile

FIGURE 60.—GENTLY DIPPING SEDIMENTARY ROCKS CUT BY NUMEROUS NEAR-VERTICAL FAULTS (UTAH).

[Approximate scale 1 : 63,360. Photographs by Army Map Service]

Sedimentary rocks are indicated particularly by topographic expression. Jointed, resistant sandstone beds stand in bold cliffs, *A*. Soft rocks have lesser angles of slope. Strong photographic tone differences mark contacts of some rock units, as at *B*; locally vegetation changes are suggestive of different rock types, *C*.

Lava flow, *D*, cuts discordantly across formational contacts. Remnant lava flow at *E* appears to have been continuous with flow at *D*. Small cinder cone, *F*, demonstrates use of shape as a recognition element of constructional landforms.

Faults are commonly marked by conspicuous topographic alinements (*G*, *H*). Throw on fault *G* is about 100 feet; on *H* the throw is about 150 feet. Note narrow alinements of vegetation marking faults, *K*.

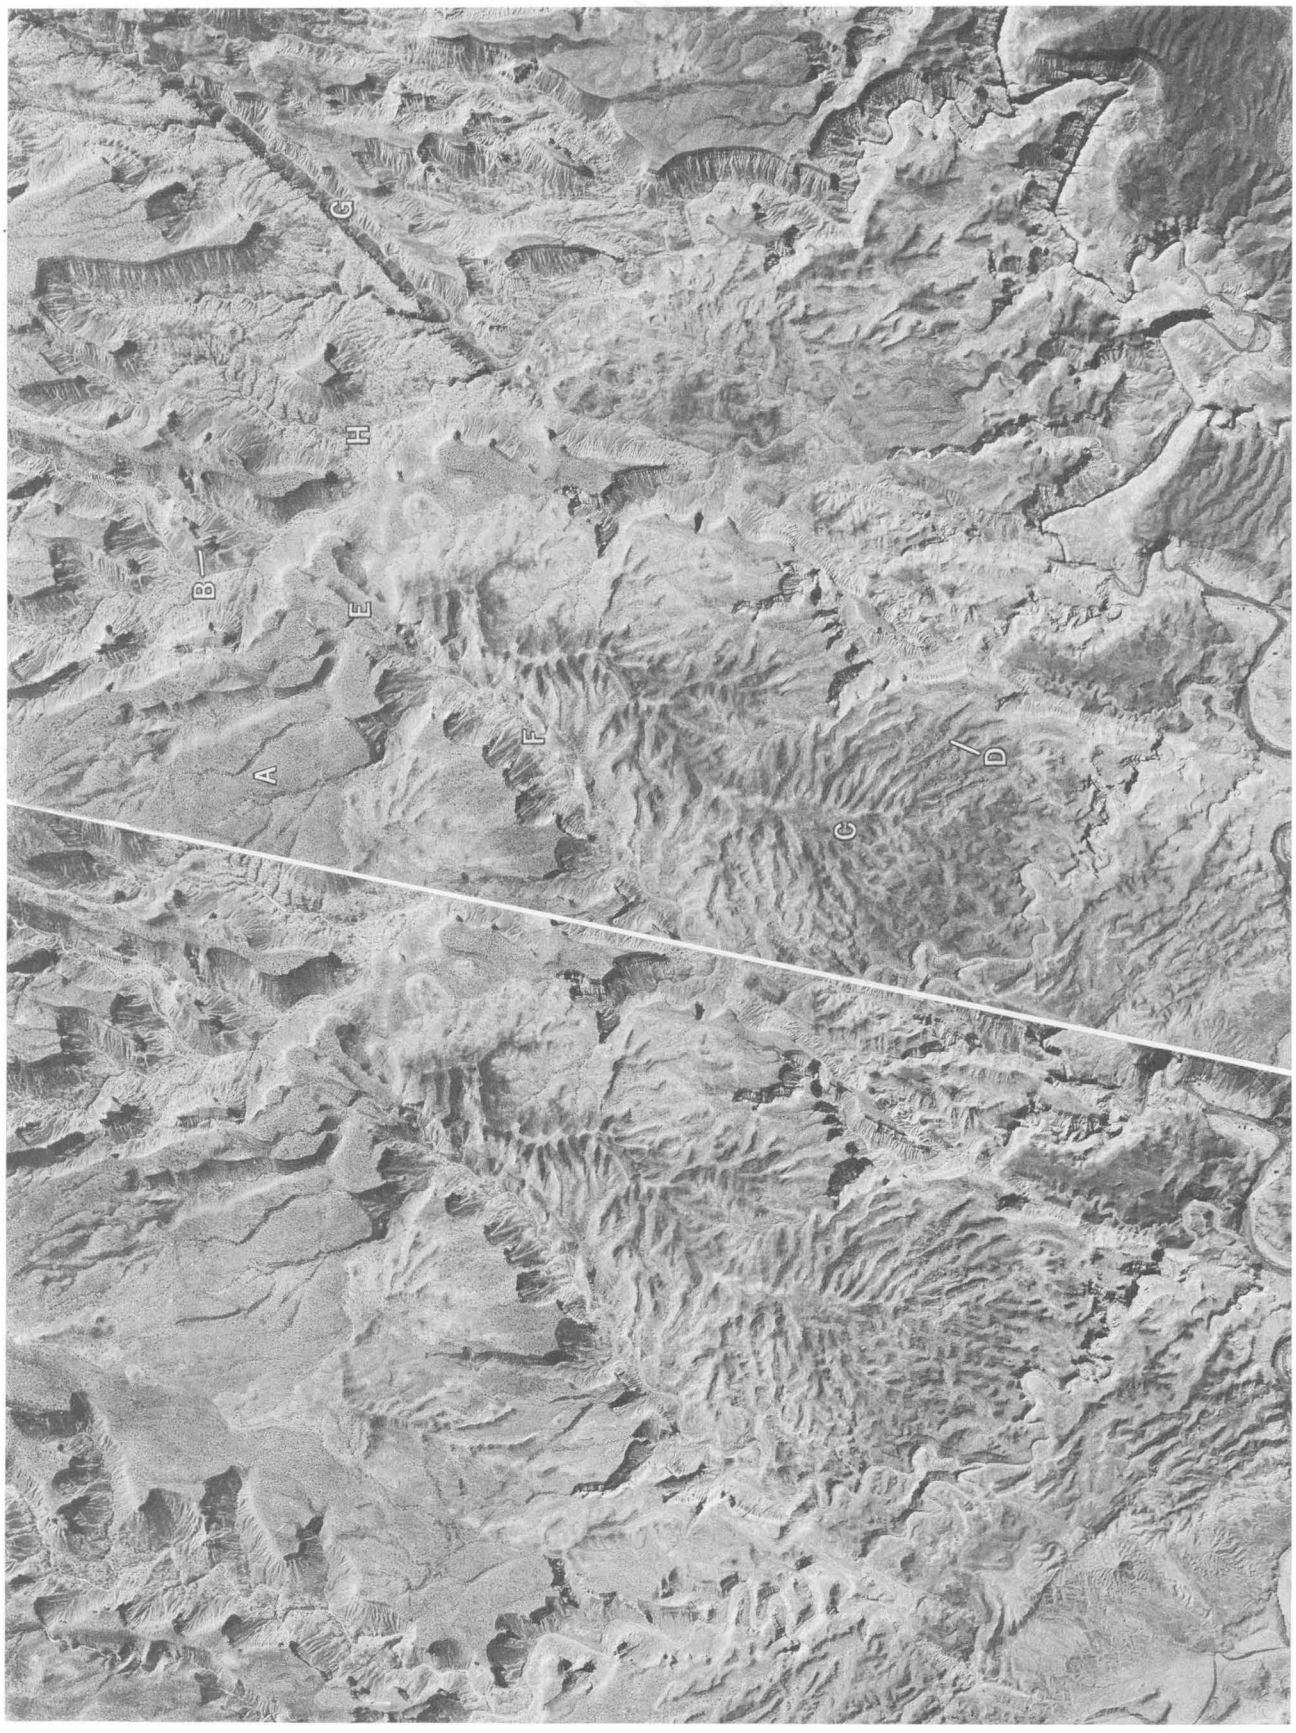
FIGURE 61.—FLAT-LYING BEDS OF SANDSTONE, LIMESTONE, AND SHALE (TEXAS).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Limestone caprock, *A*, shows a concentration of oak trees along rim but not across capping bench, which is covered by a veneer of cherty conglomerate. Sandstone break at *B* also has oak trees. Certain oaks have an affinity for limestone soils and some for sandy soils, but oak types are not distinguishable on conventional black-and-white photographs at a scale of 1:20,000. Shale valleys are covered with mesquite and locally have stock tanks, *C*, which suggest underlying impermeable materials. Note dendritic drainage and distribution of vegetation bands along the topographic contour, which in places form closed loops and suggest flat-lying or nearly flat-lying beds.



Stereoscopic pair

Approximately 1 mile

553966 O-60—6

FIGURE 62.—AREA OF FAULTED, GENTLY DIPPING SEDIMENTARY ROCKS (UTAH).

[Approximate scale 1 : 37,000. Photographs by U.S. Geological Survey]

Strong contrasts in drainage densities and in erosional features of the terrain result from different sedimentary rock types. Coarse-textured drainage of little-dissected area, *A*, marks a persistent limestone bed that locally forms bluffs. These bluffs overlie fine-grained sandstone and shale, *B*, which have a lesser angle of slope than the limestone, although the difference in slope angle is masked by the vertical exaggeration of the stereoscopic model. Note that top of limestone and topographic surface coincide permitting ready estimate of the amount of dip. Dark-toned shale and fine-grained sandstone and sandy shale at *C* show fine-textured drainage and erosional topography. Note closely spaced joints in fine-grained sandstone beds at *D*. Vertical offsets of resistant limestone bed at *E* are conspicuous. Drainage along trace of faults is prominent at *F* and *G*. A lower sandstone, *H*, contrasts locally with overlying dark sandstone and shale as a result of its light photographic tone and cover of scattered small trees.

Stereoscopic pair

Approximately 1 mile

FIGURE 63.—SHALE IN SEMIARID CLIMATIC AREA (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Fine-textured drainage is typical of shale and other fine-grained clastic rock types. Relief is commonly subdued and divide areas gently rounded. Note that rounding of some divide areas may not be conspicuous because of vertical exaggeration of the stereoscopic model. For example, the relief at *B* is only about 70 feet. The fine-textured drainage and erosional topography suggest plastic soils. The numerous angular crenulations in minor tributaries probably reflect closely spaced joints. Thin light-toned bands, *A*, are expressions of bedding.

Stereoscopic pair

Approximately 1 mile

FIGURE 64.—SHALE AND LIMESTONE IN HUMID CLIMATIC AREA (VIRGINIA).

[Approximate scale 1 : 43,000. Photographs by U.S. Geological Survey]

Gently dipping shale, *A*, shows a fine-textured drainage. Main streams draining shale flow almost directly in the downdip direction. Limestone underlies anticlinal ridge, *B*. Sinkholes are present locally, *C*, but are not conspicuous within the area. In general the limestone areas are less dissected than shale areas because of better internal drainage in limestone. Valley, *D*, is underlain by shale. Note discordance of strike of steeply dipping beds, *E*, with scarp, *F*, which suggests presence of a fault along this topographic break in slope. Thin resistant bed of sandstone, *G*, crops out conspicuously on flank of anticlinal ridge. Trellis drainage in area *D* is typical of folded sedimentary rocks.

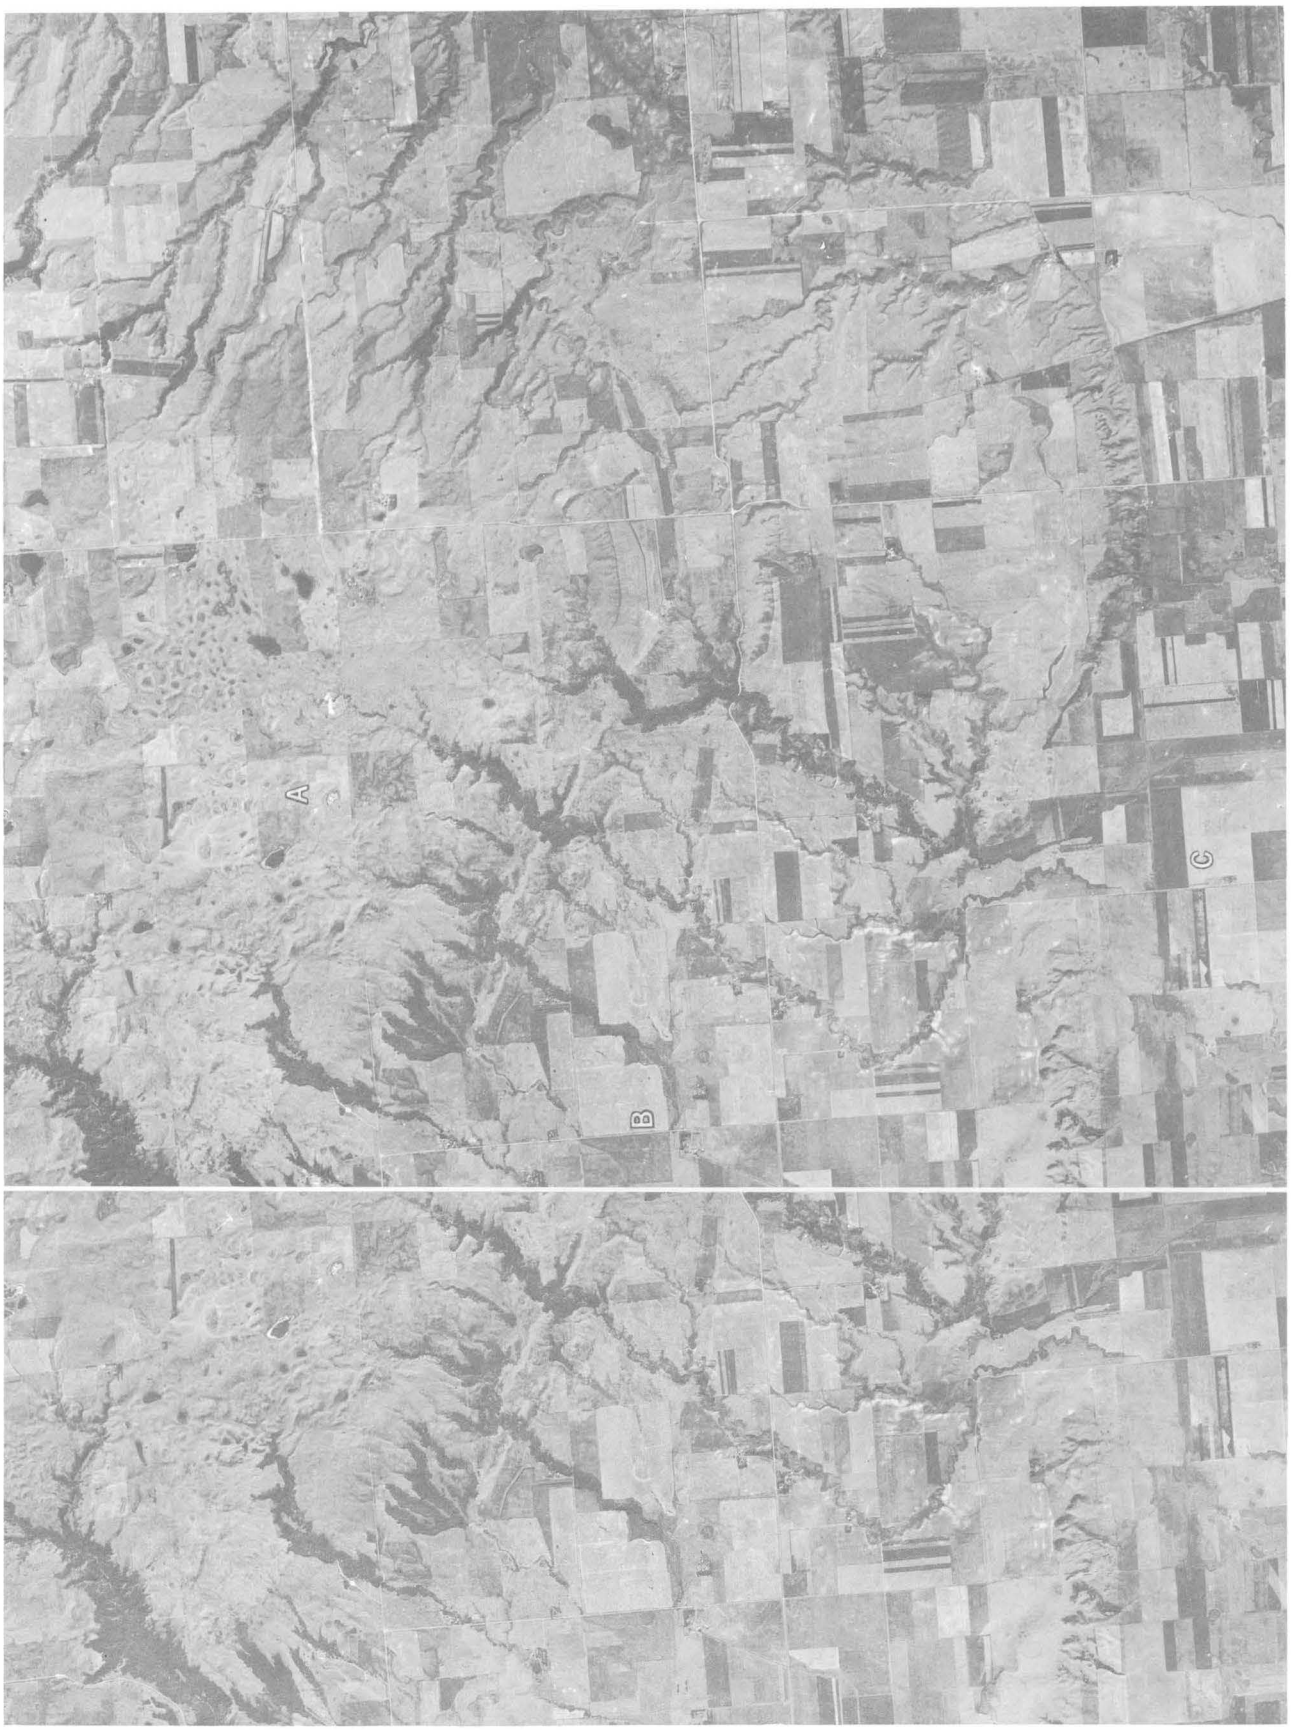
Stereoscopic pair

Approximately 1 mile

FIGURE 65.—AREA OF GENTLY DIPPING LIMESTONE AND SHALE (PENNSYLVANIA).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Impermeable shale, *A*, has a greater resistance to erosion than the limestone, *B*, and stands topographically high in this area. The contact of shale and limestone is marked by a pronounced topographic break, as at *C*. The shale has been noticeably dissected by stream erosion in contrast to the limestone in which drainage is in large part internal. Note orchards in well-drained limestone areas. Vegetation along stream valleys in the shale accentuates the drainage contrast of shale and limestone areas. Soil mottling, *D*, in limestone areas occurs where soil cover is thin and allows differences in moisture conditions, believed to result from drainage channels in the limestone bedrock, to stand out. Despite good drainage in the limestone area residual soils developed on limestone may react to engineering tests as a plastic soil and not as a granular soil. Limestone quarry is at *E*.



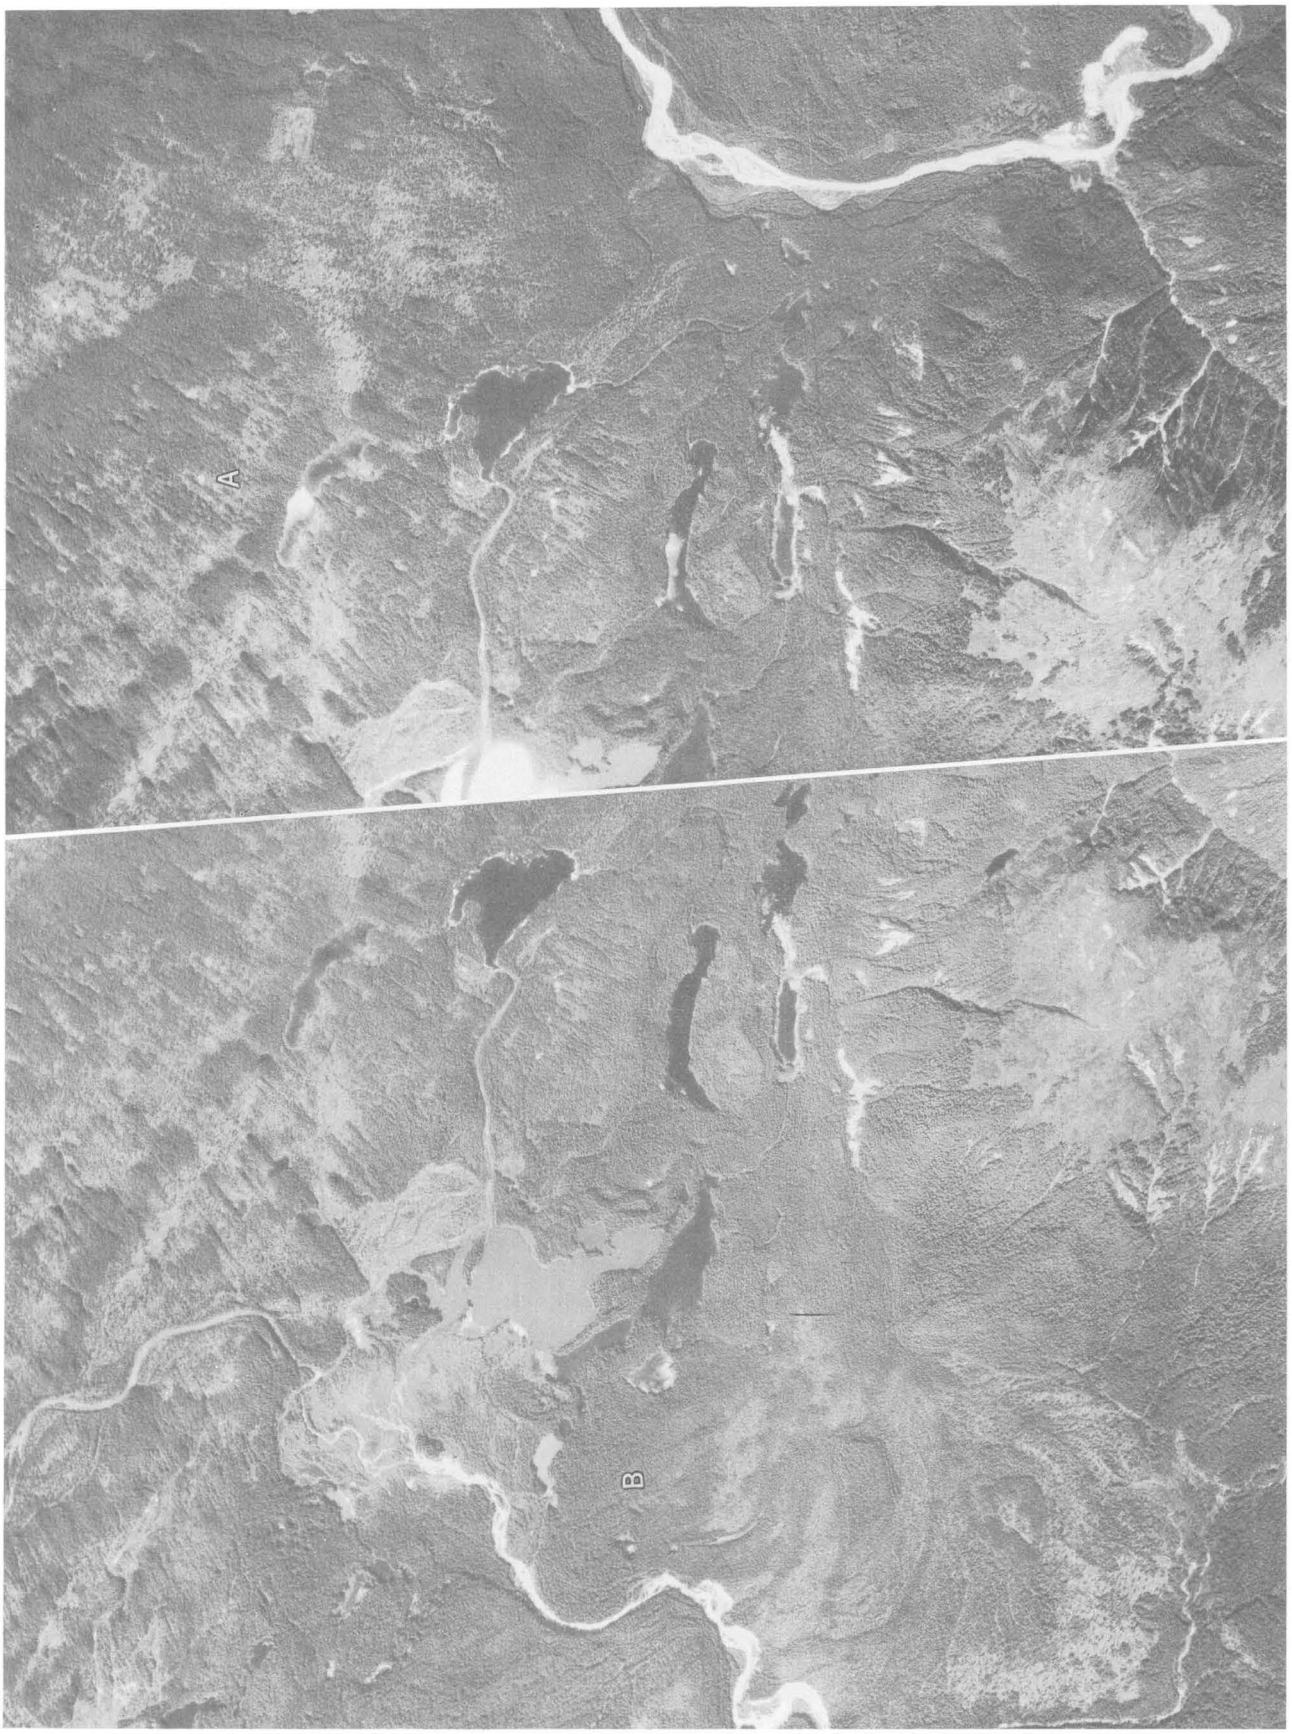
Stereoscopic pair

Approximately 1 mile

FIGURE 66.—AREA MANTLED BY GLACIAL DEPOSITS (SOUTH DAKOTA).

[Approximate scale 1 : 60,000. Photographs by Army Map Service]

Topographically high area, *A*, with typical knob-and-kettle topography is covered by morainal material; ponds are common but surface drainage channels are conspicuously absent. Rim of high ground has been noticeably dissected by deep channels. The distribution of these channels, accentuated by dark-toned vegetation, forms a radial pattern similar to that over some subsurface structures in other areas. Drainage disappears in permeable material, *B*, surrounding the high area. Contrast lack of surface drainage rills in moraine at *A*, where drainage is poor, as indicated by ponds, with lack of surface drainage rills in outwash at *B*, where internal drainage is good. Well-drained area, *C*, probably also represents glacial outwash.



A
B
Stereoscopic pair
Approximately 1 mile

FIGURE 67.—GLACIATED AREA IN SOUTHEASTERN ALASKA.

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

Conspicuous linear trends, *A*, represent glacial grooving. These lineations, except for the fanning out in the direction of ice movement, may appear on photographs similar to lineations that represent foliation in metamorphic rocks. Drumlinoid features that give rise to this linear pattern are generally found in broad, flat, and topographically low areas, such as the floors of broad valleys. Commonly the drumlinoid features are elongated parallel or subparallel to the valley or general topographic grain. Lineations representing foliation on the other hand may transect or parallel the topographic grain; unlike drumlinoid features they are not restricted to any one topographic level. Pock-marked area, *B*, is glacial outwash and probably some glacial lake deposits.

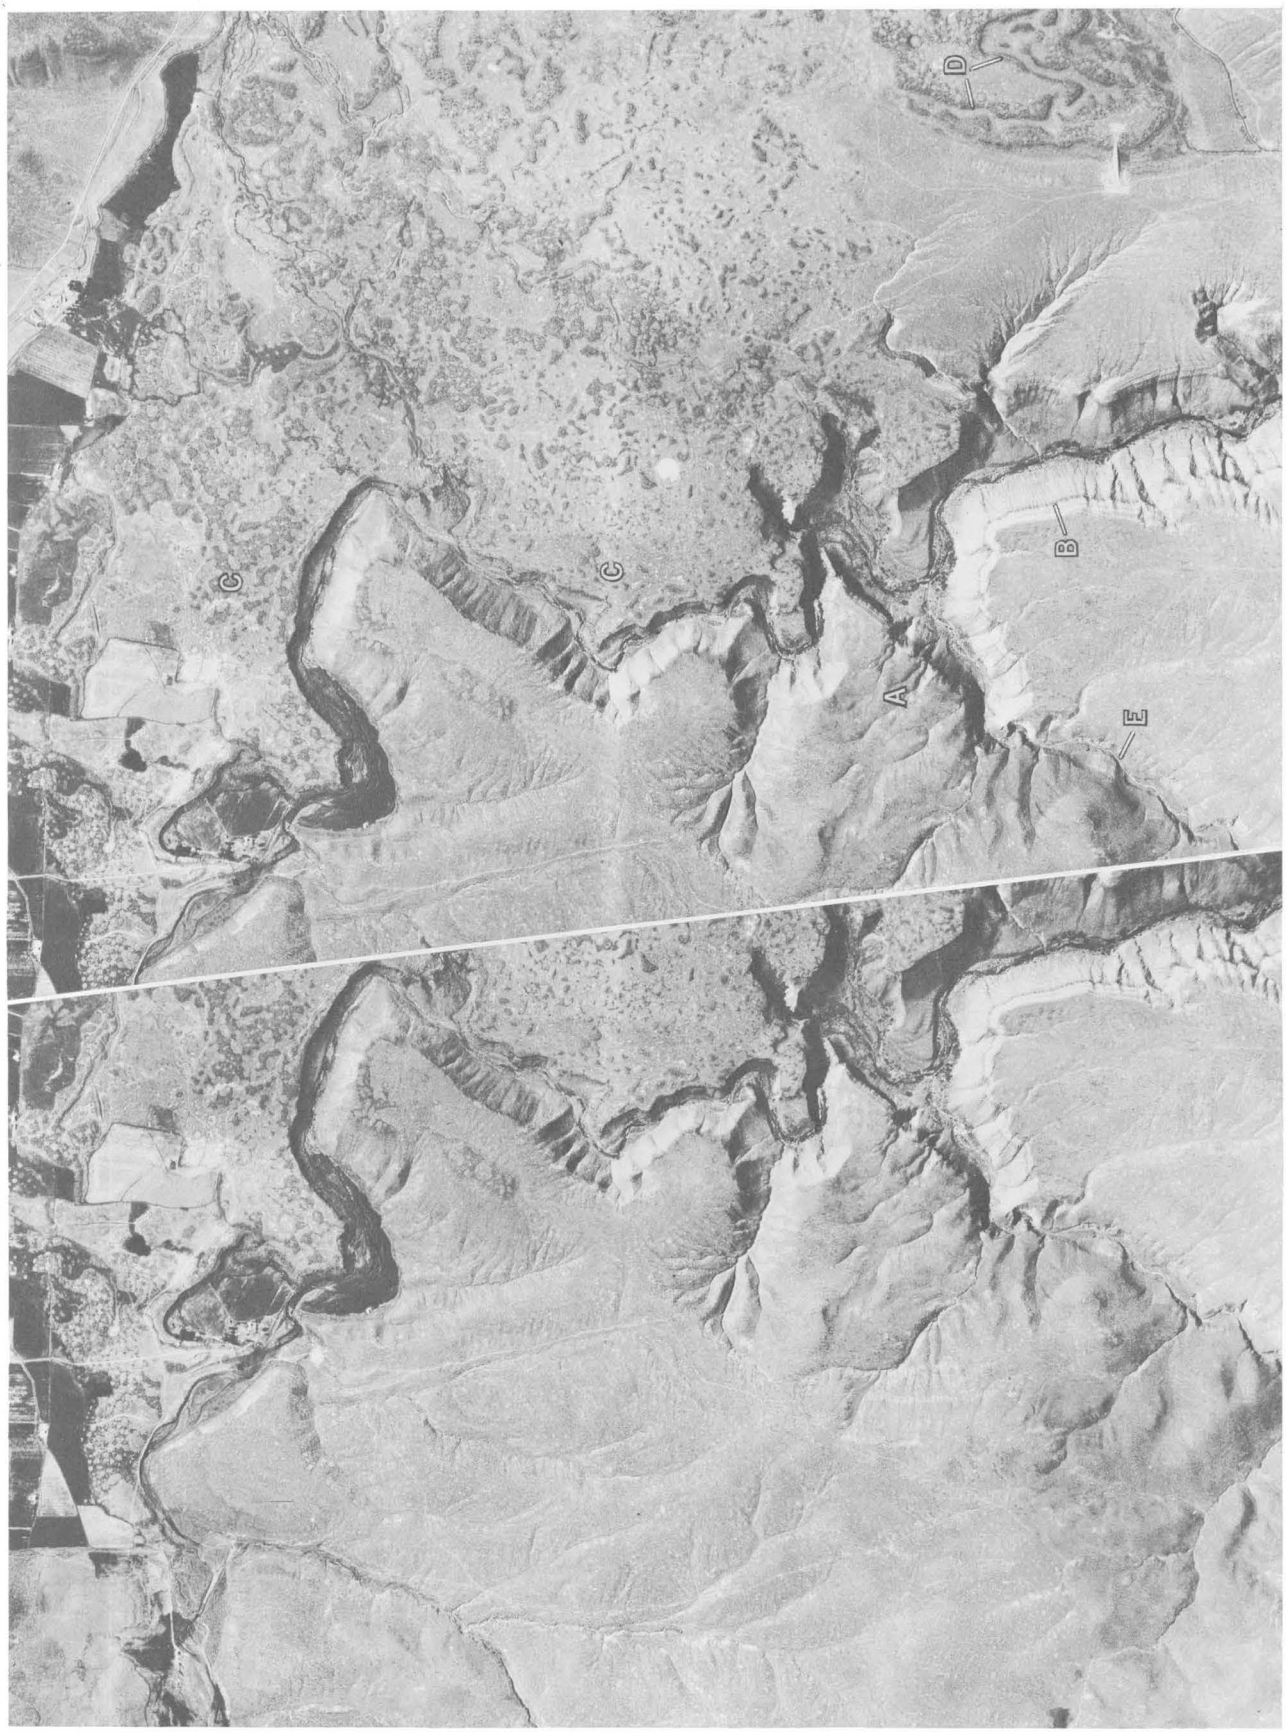
FIGURE 68.—APPROXIMATELY FLAT-LYING LIMESTONE AND INTERBEDDED SANDSTONE AND MARLSTONE BEDS COVERED LOCALLY BY ALLUVIUM AND WINDBLOWN DEPOSITS (TEXAS).

[Approximate scale 1 : 63,360. Photographs by Army Map Service]

Rounded dark-toned depressions are sink holes that mark area of limestone. Drainage is primarily internal and few surface drainage channels may be seen; a few short surface rills drain into the sink holes, as at *A*. In contrast to the limestone area, surface drainage is conspicuously developed in the interbedded sandstone and marlstone, *B*, but becomes less well developed in permeable alluvium and windblown deposits, *C*.



Stereoscopic pair

Approximately 1 mile

FIGURE 69.—AREA OF BASALT FLOWS (IDAHO).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

The oldest basalt, *A*, shows subdued rounded topography and well-developed surface drainage. A younger basalt, *B*, is interbedded with light-toned sedimentary rocks. Some surface drainage has developed on the sedimentary rocks. The youngest basalt, *C*, shows a "lizard skin" appearance on aerial photographs; locally a collapse structure may be present as at *D*. Almost no integrated surface drainage is present on the youngest basalt. Stream *E* flows in a fault valley. The fault is younger than, and separates, basalts *A* and *B*; basalt *A* has been upthrown.

Stereoscopic pair
Approximately 1 mile

FIGURE 70.—AREA OF GRANITE (SOUTH DAKOTA).

[Approximate scale 1 : 24,000. Photographs by U.S. Geological Survey]

Dendritic drainage, seen best in stereoscopic view, is typical of many terrains underlain by intrusive igneous rocks or other generally homogeneous rocks. The irregularly spaced joints in several different orientations are characteristic of granite and other intrusive rocks; extremely irregular topography is also common in such terrain. Banding, suggestive of sedimentary or metamorphic rocks, is absent. The occurrence of trees predominantly of one variety and the lack of conspicuous preferred orientation of vegetation is suggestive of uniform composition of bedrock.

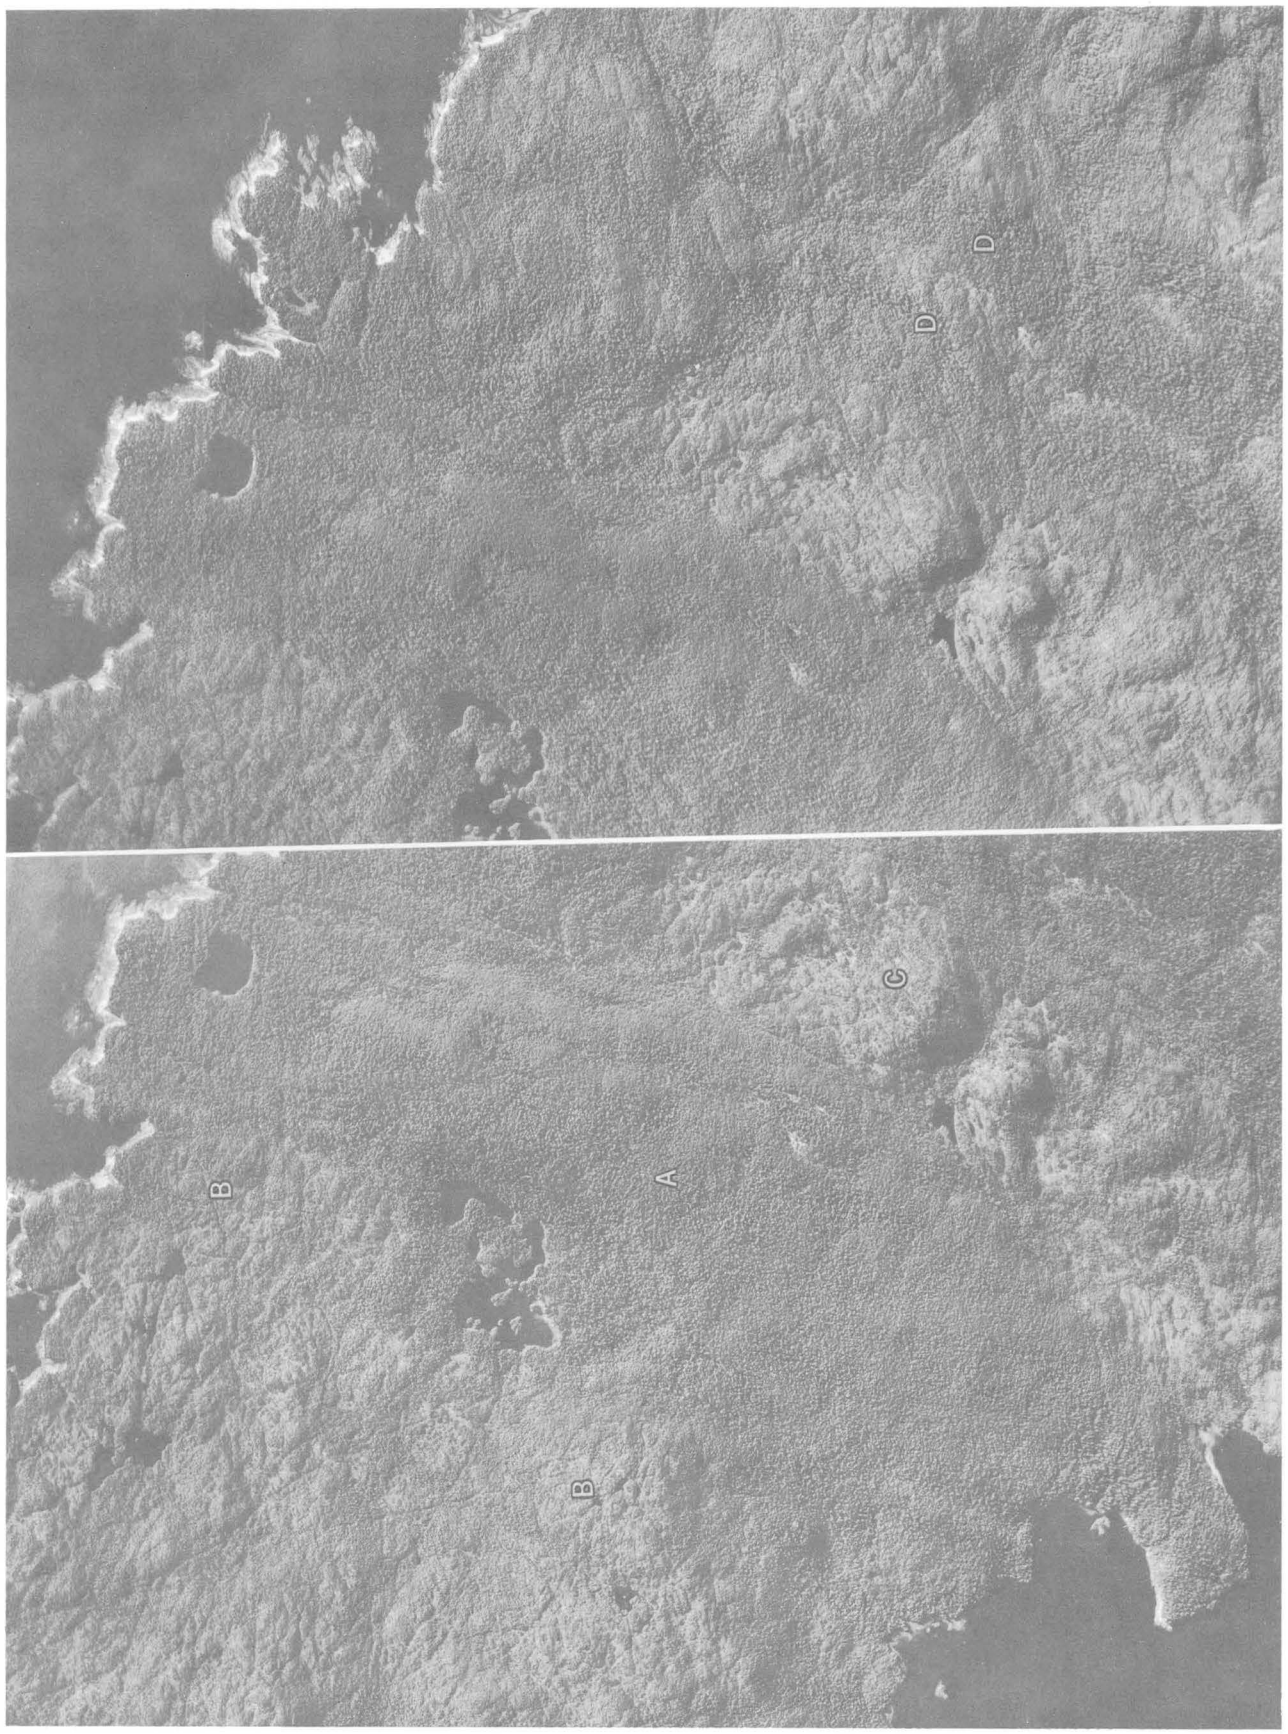
Stereoscopic pair

Approximately 1 mile

FIGURE 71.—AREA OF GRANITIC INTRUSIVE ROCKS (WYOMING).

[Approximate scale 1 : 28,000. Photographs by U.S. Geological Survey]

Profuse, irregularly spaced joints in several different orientations are typical, although not necessarily diagnostic, of intrusive igneous rocks. The massive character of the rocks and apparent lack of bedding in turn suggest igneous intrusive rocks, although locally the rocks shown appear similar to some highly fractured massive sandstone. Conspicuous rectilinear depressions, as at *A*, marked by dark-toned vegetation, are shear zones that are more easily eroded than surrounding rock areas, and probably have a higher concentration of moisture that supports vegetation growth. In places, as at *B*, older shear zones have been offset by younger fractures. Note strong control of drainage by faults and joints.



Stereoscopic pair

Approximately 1 mile

FIGURE 72.—AREA SHOWING VEGETATION DIFFERENCES IN IGNEOUS-METAMORPHIC TERRAIN (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

Dense stand of coniferous trees, *A*, is typical of massive marble and related carbonate rocks in this area. Diorite, *B*, has only patchy tree growth but shows typical crisscross joint pattern of short lineations common in many intrusive rocks. Area *C* is schist. The surface expression of the schist is similar to that of the diorite in patchy tree cover and irregular topography but the schist has a dominant lineation direction not present in the intrusive rocks. Vegetation bands, *D*, may cover thin beds of marble. Note that gently curved vegetation bands suggest steeply dipping rock units.

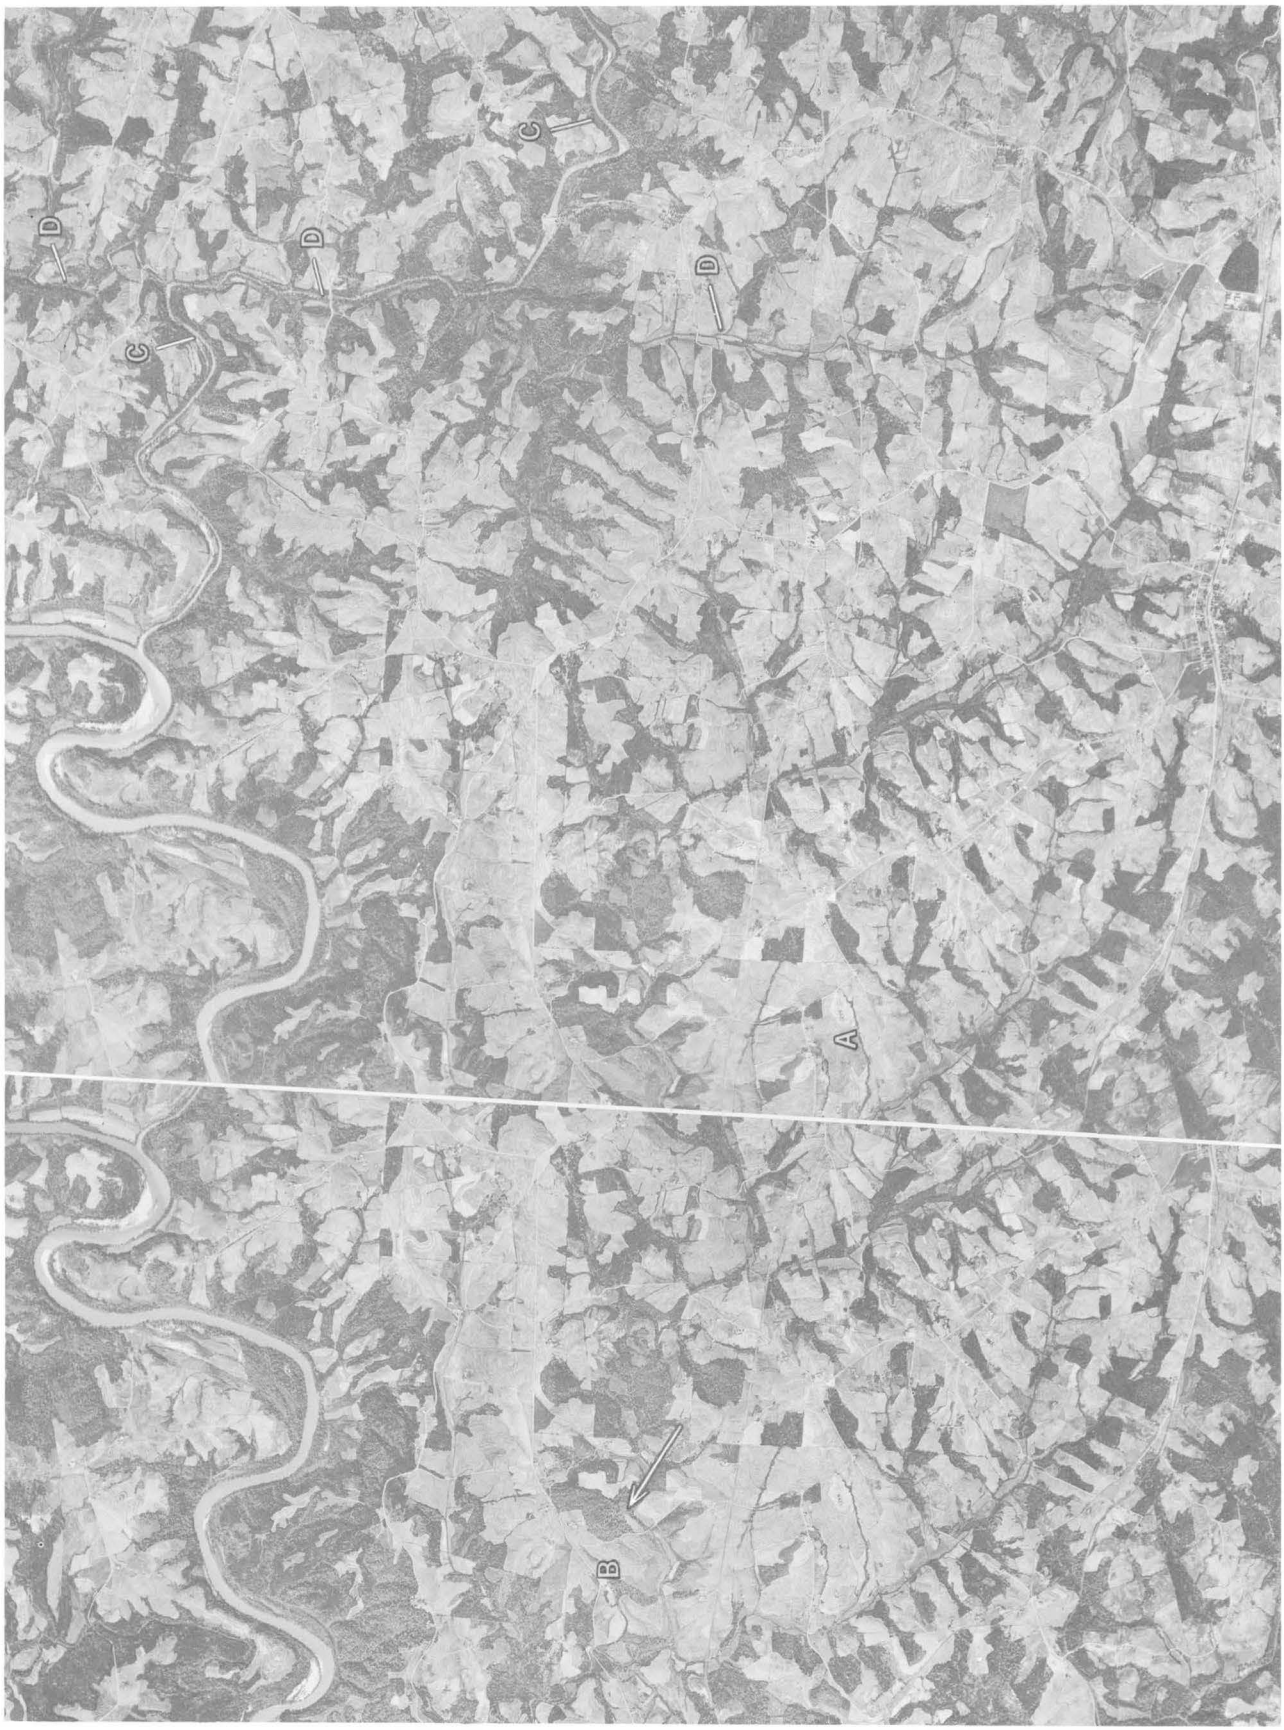
Approximately 1 mile

FIGURE 73.—AREA UNDERLAIN BY SILICIC VOLCANIC TUFFS AND FLOWS AND BEDDED ARGILLITE OR SLATE (NORTH CAROLINA).

[Approximate scale 1 : 58,000. Photographs by Army Map Service]

Major streams, *A*, are developed along the regional cross-joint direction. Roads extending generally parallel to the major streams accentuate the cross-joint direction. Minor tributary streams flow predominantly parallel to the regional structural trend and at right angles to the cross joints. Hills are commonly elongate in the direction of the regional strike, which may represent foliation or flow cleavage rather than bedding. In such low-relief areas the extensive land-use pattern tends to obscure structural trends; commonly the structural trends can be better observed from a mosaic composed of several photographs. Any one stereoscopic pair can only show a small part of the regional geologic structure. Structural interpretation may also be facilitated by study of separate drainage maps, as in figure 8.



Stereoscopic pair

Approximately 1 mile

553966 O-60—7

FIGURE 74.—AREA OF FOLDED, FAULTED, AND HIGHLY METAMORPHOSED ROCKS (NORTH CAROLINA).

[Approximate scale 1 : 57,000. Photographs by Army Map Service]

This pair of photographs illustrates a use of drainage characteristics in the interpretation of geologic structure. Where dips are gentle, tributary streams developed on the updip side of a strike valley commonly will be longer than tributary streams developed on the downdip side of the valley, as at *A*. The direction of dip of strata is thus indicated. Length relations of streams are commonly best studied on a separate drainage overlay (see fig. 7) where vegetation and other obscuring features in the stereoscopic model are not present. In the area shown, a plunging fold is also suggested by the distribution of photographic tones and gentle curvature of streams around the nose, *B*, of the fold. Arrow indicates direction of plunge. Many streams in highly metamorphosed terrain have developed in response to, and therefore reflect, the strike and dip of foliation rather than bedding. Prominent cross joints are expressed by linear segments of major streams, as at *C*, and by alinement of vegetation along some tributary streams. Note conspicuous fault indicated by alinement of stream segments, *D*; this fault is inconspicuous on the ground.

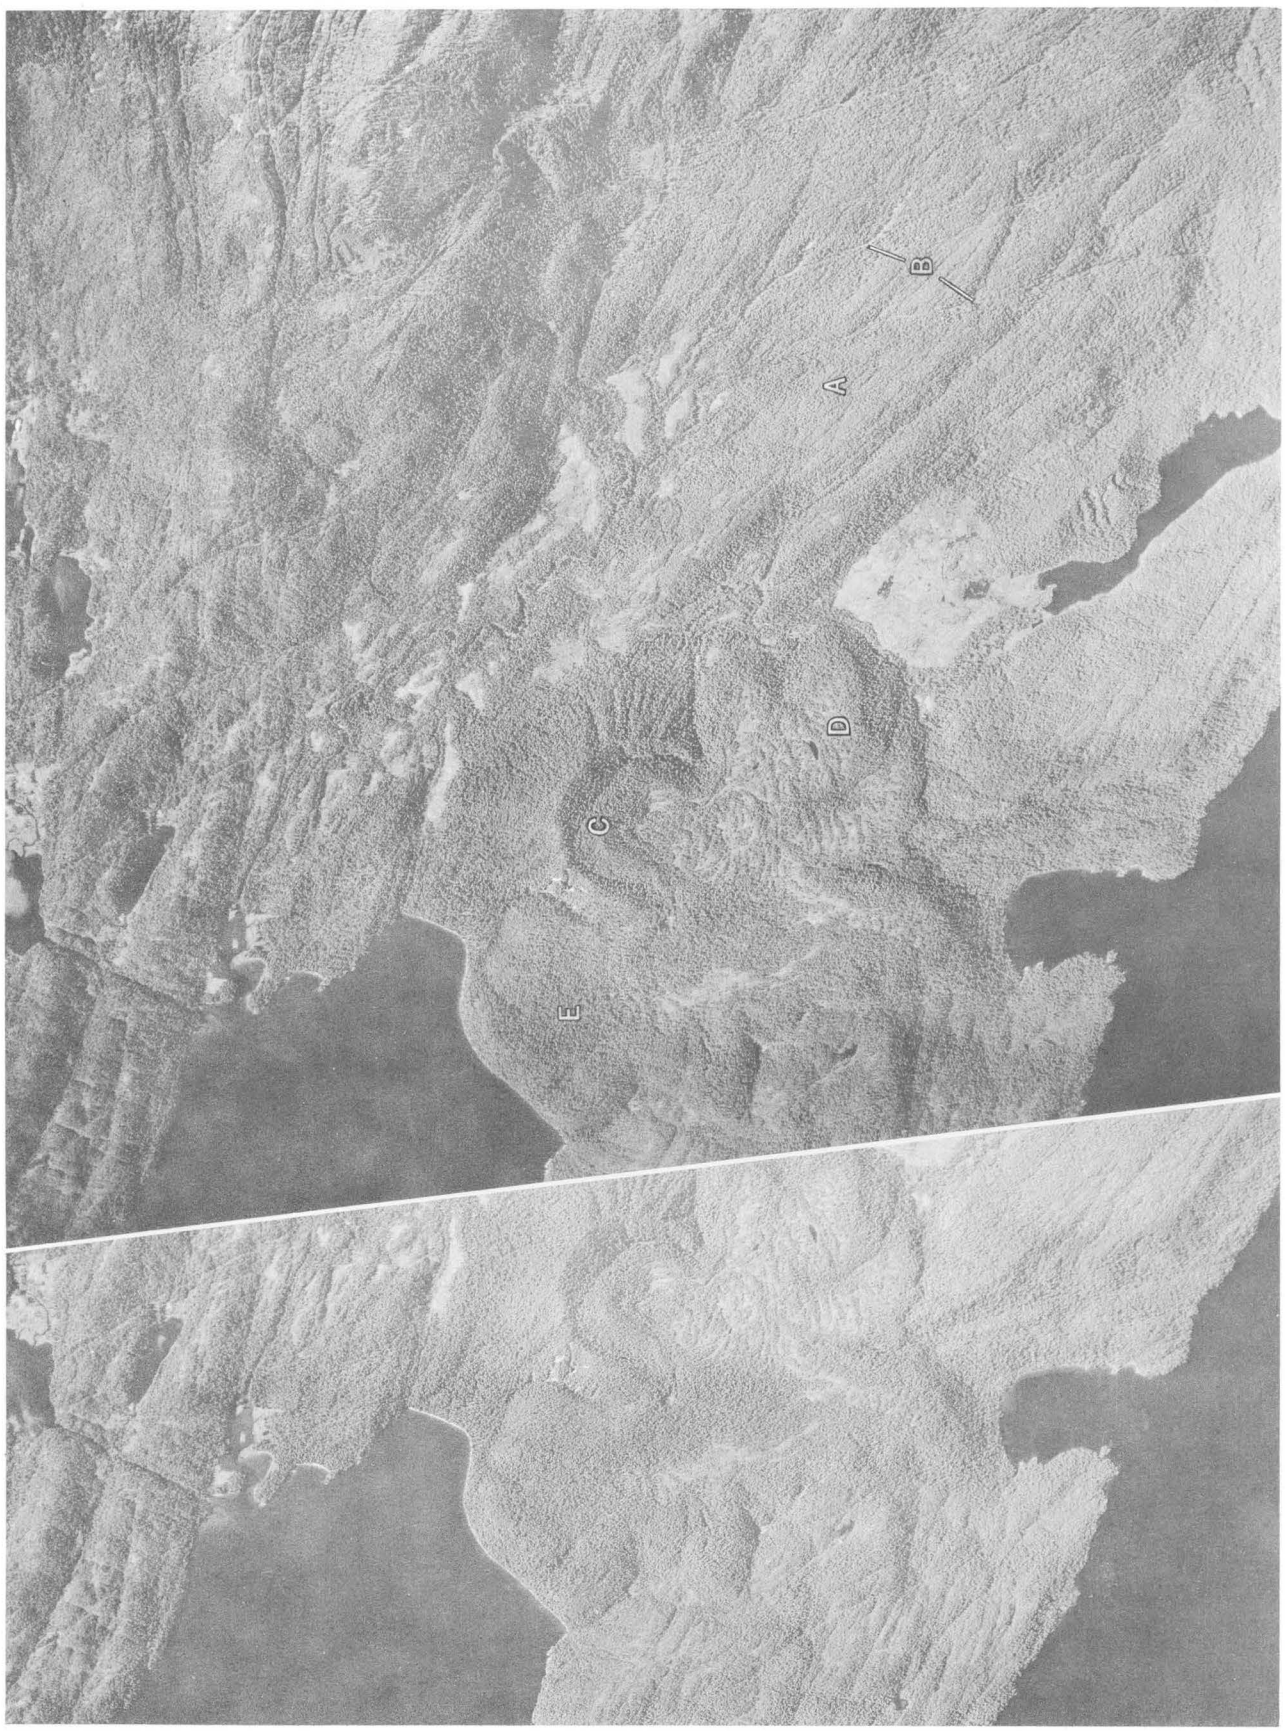
Stereoscopic pair
Approximately 1 mile

FIGURE 75.—AREA UNDERLAIN BY PHYLLITE AND SLIGHTLY METAMORPHOSED SLATY ROCKS (ALABAMA).

[Approximate scale 1 : 29,000. Photographs by U.S. Geological Survey]

Poorly resistant phyllite and slightly metamorphosed slaty rocks here are characterized by fine-textured drainage, commonly found in fine-grained clastic rocks. The area also has a fine-textured erosional topography. Several conspicuous linear trends, *A*, are at right angles to the regional strike of bedding. These trends probably represent regional cross joints. In areas of metamorphic rocks the prominent regional cross joints commonly are widely spaced and streams flow along them. The linear trend of the stream at *B* is parallel to the regional strike of bedding. There is no direct surface manifestation of bedding. Headwater tributaries form a generally dendritic drainage pattern that suggests uniformity of rock type, but principal streams show rectangular drainage probably influenced by bedding and cross joints.



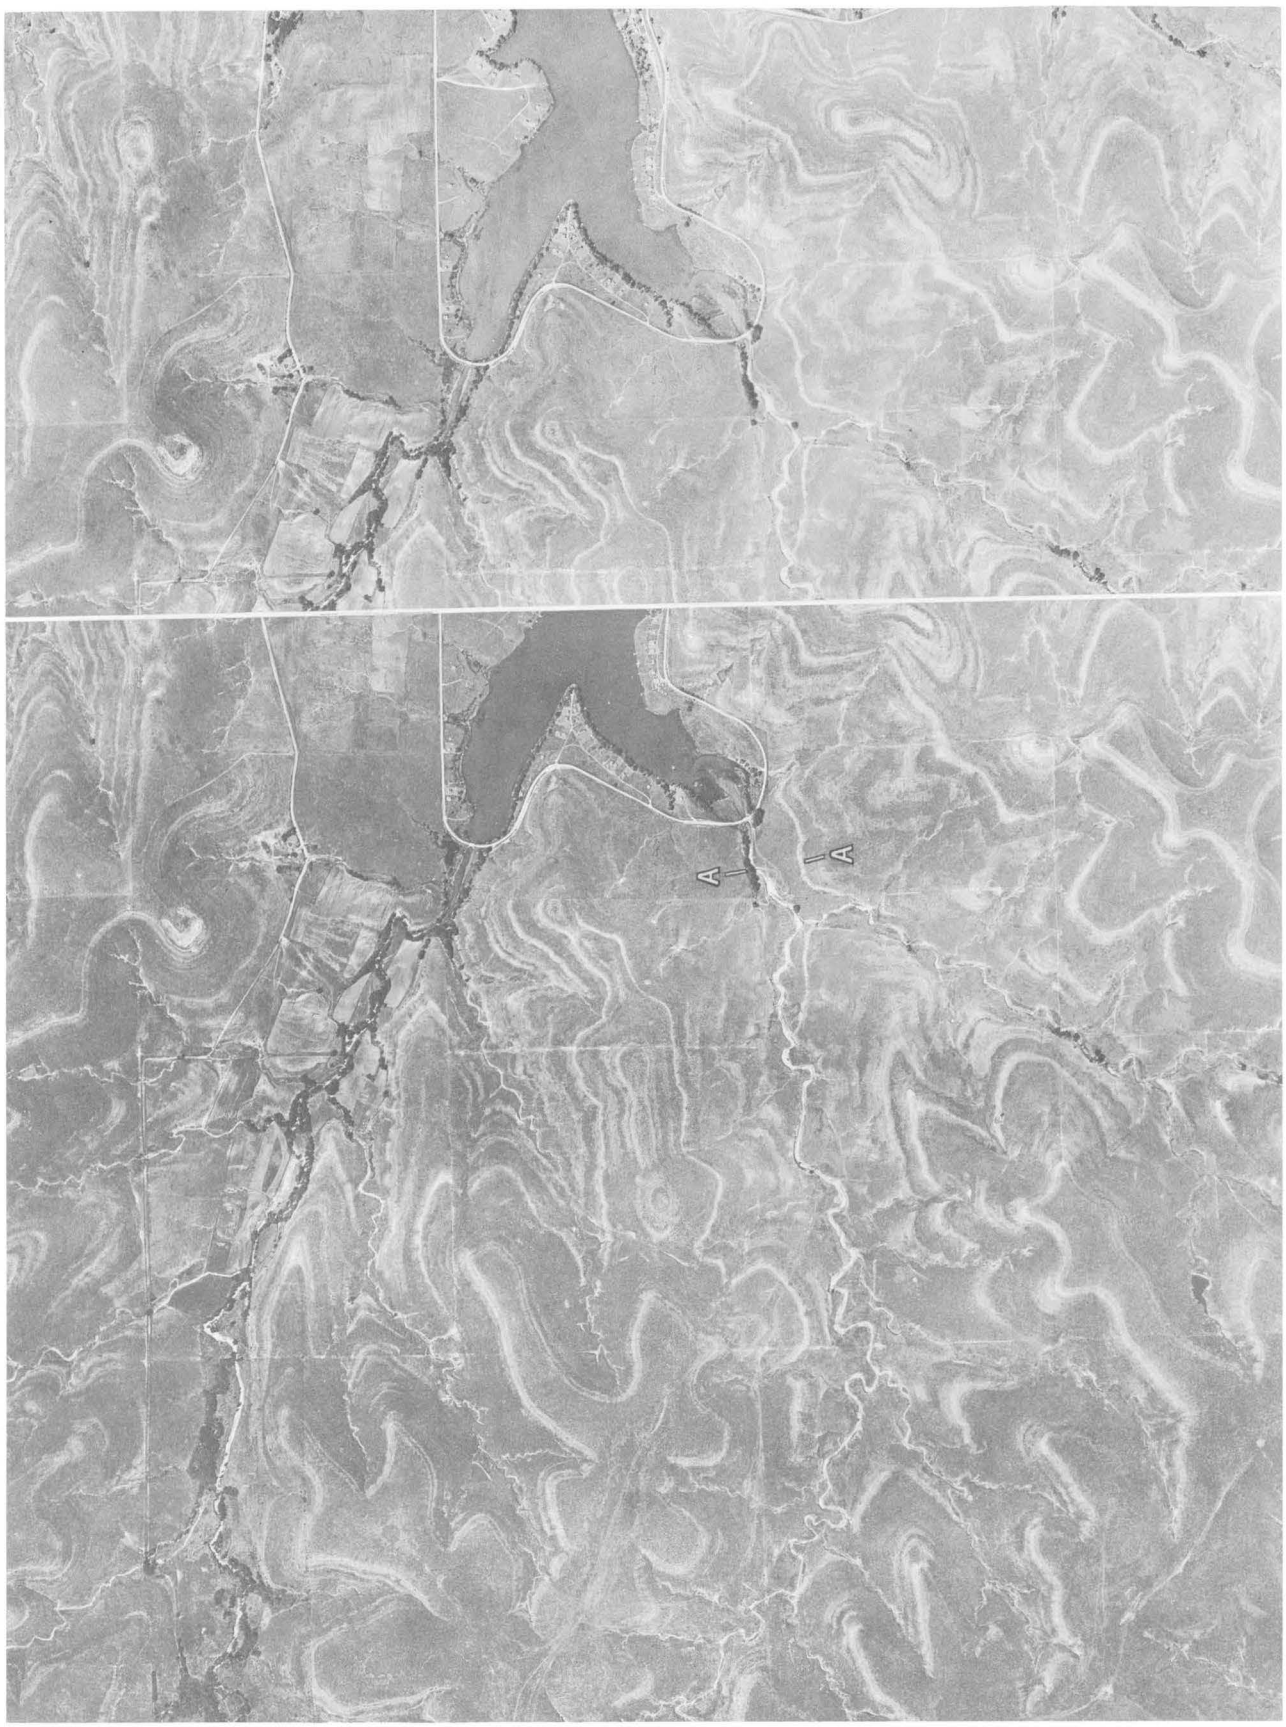
Stereoscopic pair

Approximately 1 mile

FIGURE 76.—HEAVILY VEGETATED TERRAIN UNDERLAIN BY METAMORPHIC AND EXTRUSIVE VOLCANIC ROCKS (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Geological Survey]

Numerous subparallel lineations, *A*, represented primarily by rectilinear depressions that channel the drainage, are expressions of foliation in the metamorphic rocks. Conspicuous rectilinear depressions, *B*, transecting the foliation direction, represent faults. The remnant of a recent volcanic cone, *C*, is recognized by its shape. Note lobate patterns of vegetation, *D*, suggesting areas of flow rocks. Absence of lineations in area *E* suggests that flows also are present there.



A
A
Stereoscopic pair
Approximately 1 mile

FIGURE 77.—FLAT-LYING BEDS OF LIMESTONE AND SHALE (KANSAS).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Strong contrasts in photographic tone result primarily from different lithologic characteristics of underlying formations; dark-toned beds are shale with some grassy vegetation; light-toned beds are limestone. The near-coincidence of bedding traces and topographic contours, closed loops of tonal patterns, as well as the dendritic drainage pattern are typical of flat-lying beds. Small thickness of limestone interbeds is not conducive to development of sink holes. In some places individual limestone beds can be distinguished on the basis of weathering and erosional characteristics; massive cherty limestone benches may show rounded rims, whereas thin platy limestone benches may show a sharp break at the rim. Abundant trees and shrubs along part of bed *A* suggest a plentiful supply of water. Bed *A* is locally an aquifer.

C
Stereoscopic pair
Approximately 1 mile

FIGURE 78.—FLAT-LYING BEDS OF SANDSTONE, LIMESTONE, AND SHALE (TEXAS).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Flat-lying beds are indicated by benchlike landform, extension of tonal bands along topographic contour, and by dendritic drainage. Dark photographic tone on sandstone caprock, *A*, results from growth of oak trees. Benches of limestone, *B*, exhibit concentration of oak growth along rims but not across flats. Valley areas are underlain by shale, which is covered predominantly by mesquite growth. Stock tanks, *C*, are common in impermeable material and where present suggest shale in this region.

Approximately 1 mile

FIGURE 79.—AREA OF SPARSE OUTCROPS UNDERLAIN LARGELY BY GENTLY FOLDED SANDSTONE, CONGLOMERATE, AND SHALE (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

Dip slopes are characterized by few streams in contrast to back slopes on which a system of numerous subparallel streams has developed. Drainage in the dip-slope direction is generally coarse textured except for profuse channels developed at heads of tributaries. Drainage on the back slopes is fine textured. The textural difference, or drainage density difference, rather than any specific drainage pattern, stands out. The back slope, with its fine-textured drainage, is predominantly a shale section in contrast to the sandstone and conglomerate of the dip slope. Note horizontal offset of light-toned sandstone beds by near-vertical faults, illustrated at *A*, transverse to the strike.

Stereoscopic triplet

Approximately 1 mile

FIGURE 80.—GENTLY TO STEEPLY DIPPING SEDIMENTARY ROCKS OVERLYING SCHIST-GNEISS-GRANITE COMPLEX (WYOMING).

[Approximate scale 1 : 59,000. Photographs by Army Map Service]

Striking discordance in dip of beds can be seen between beds at *A* and *B* and between near-vertical beds at *C* and flat-lying beds at *D*. Such a discordance in dip may represent tightly folded structures in some areas but here it represents faulting. Note also the conspicuous discordance in strike between beds at *A* and *C* and between beds at *B* and *C*. The locations of fault traces may be inferred from the positions of discordant beds, but details of fault structure and positions of formation contacts cannot be seen clearly on the photographs of many parts of this complex area. Dark-toned rocks, *E*, lacking bedding or banding are schist-gneiss-granite complex. Light-toned jointed rocks, *F*, are predominantly limestone and dolomite. Where light-toned rocks are cut by a stream, as at *G*, the outcrop pattern forms a V in the direction of dip.

Stereoscopic pair

Approximately 1 mile

FIGURE 81.—GENTLY FOLDED SEDIMENTARY ROCKS (CENTRAL UTAH).

[Approximate scale 1 : 20,000. Photographs by Soil Conservation Service]

Contrasting photographic tones, representing different soil and rock types, strongly outline plunging anticline. Plunge of anticline is also indicated by stream curvature at *A* and *B*. Note that major stream has generally consistent direction of flow until it reaches anticlinal nose at *C*, at which point it is deflected in the direction of plunge of the structure. Outcrop pattern of contact between light- and dark-toned rocks, *D*, along flank of the anticline forms pronounced V's, which point in the direction of dip. Local intrusions of basalt dikes, *E*, stand in topographic relief above softer surrounding rocks.

FIGURE 82.—RING DIKE IN NEW HAMPSHIRE.

[Approximate scale 1 : 34,000. Photographs by U.S. Geological Survey]

The ring dike, composed of several types of igneous rock, is the most conspicuous feature of the terrain. Different rock types in places are reflected in the topographic expression of terrain. An outer ring and partial inner ring, *A*, composed of monzonite stand in conspicuous topographic relief. Hornblende diorite, in places foliated, forms the low areas, *B*. Some geologic contacts may be located on the basis of topography. However, specific placement of contacts cannot be made from the stereoscopic model; but in igneous terrain, where one rock type may grade into another, contacts are difficult to select in the field. The ring dike is cut by several faults, *C*, indicated by alinements of scarps, depressions, and vegetation.

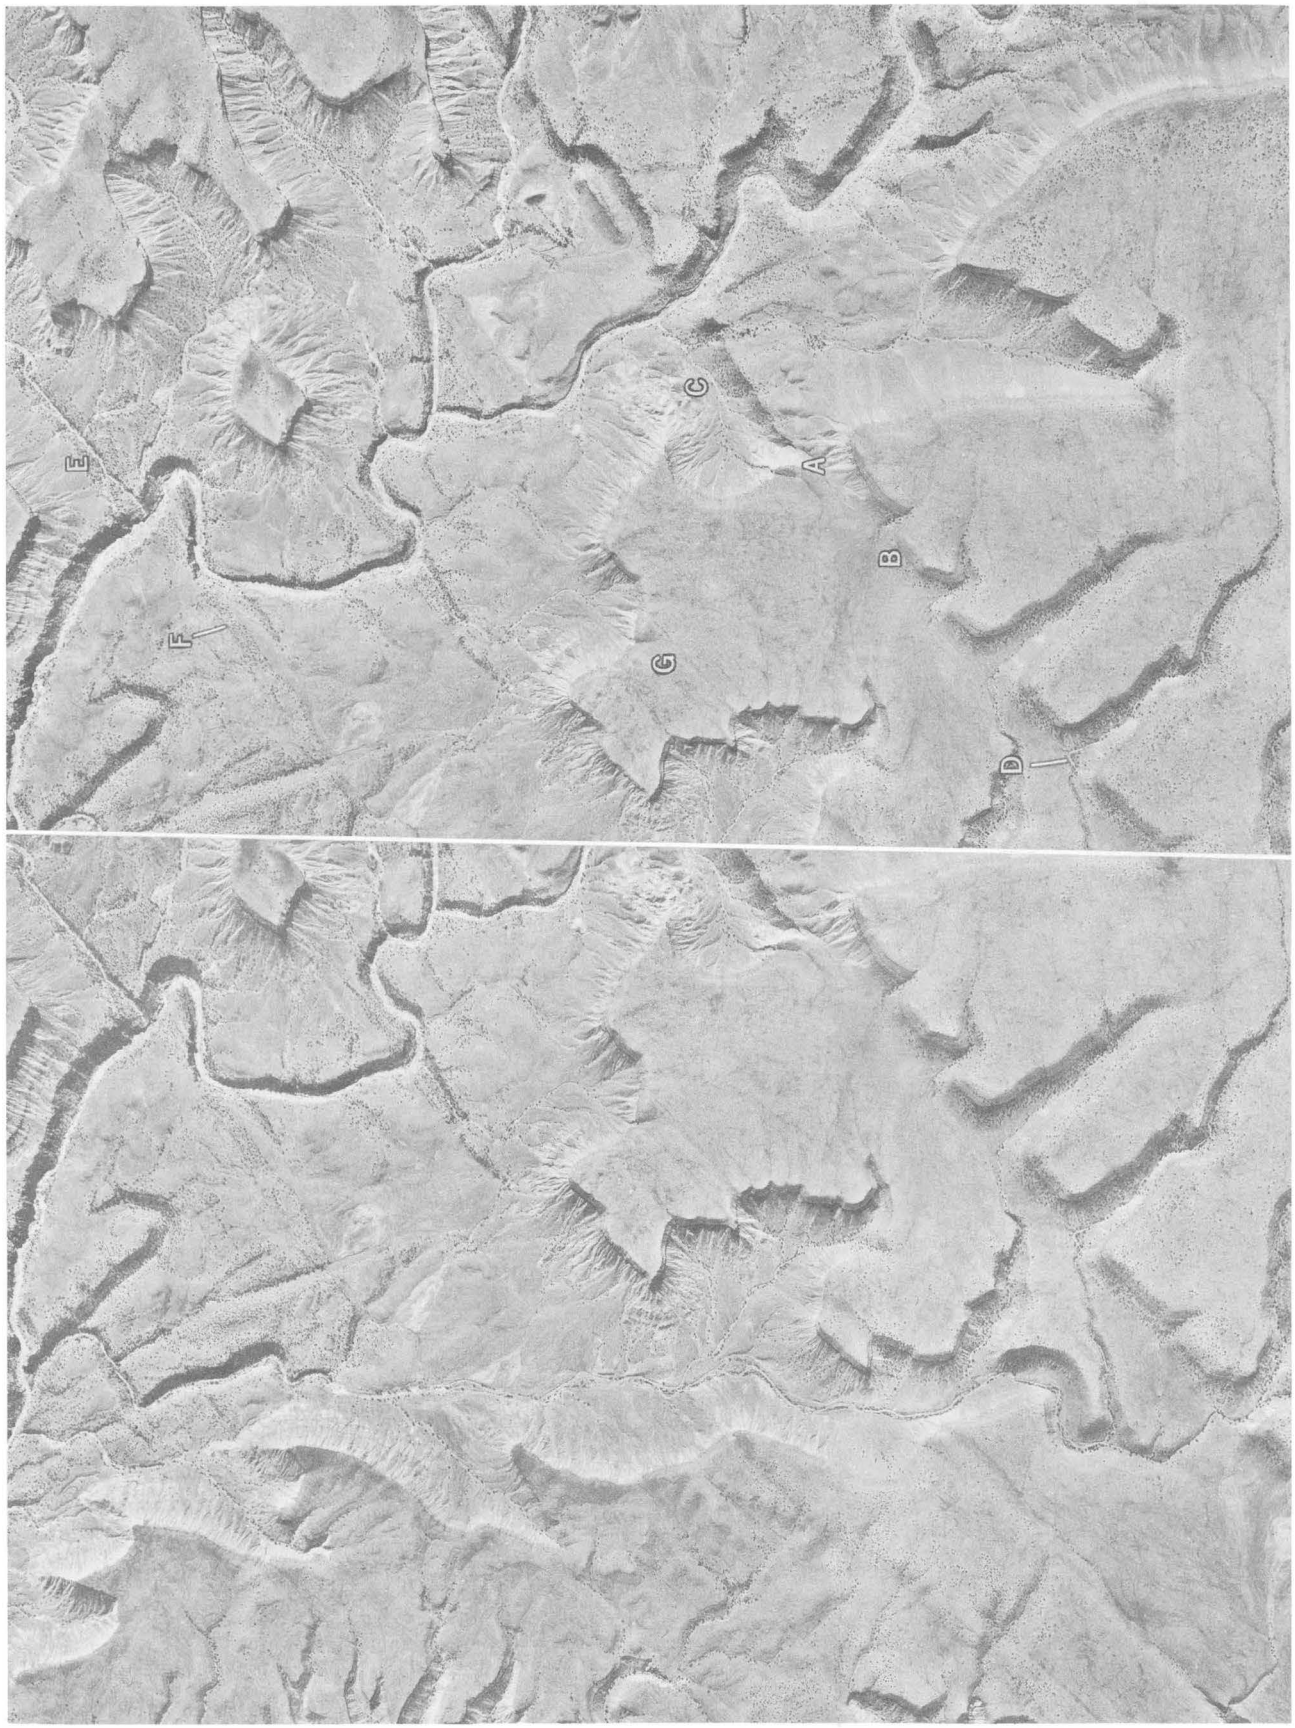
FIGURE 83.—GENTLY DIPPING SEDIMENTARY ROCKS OFFSET BY NEAR-VERTICAL FAULT (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Line separating areas of contrasting photographic tones is trace of fault. The straightness of the fault trace indicates that the fault has approximately a vertical dip. Note vertical offset of dark-toned shale bed, *A*, and difference in erosional character of topography on opposite sides of fault at *B*. Faint trace of fault in alluvium at *C* is locally marked by differences in drainage on opposite sides of the fault. Light-toned sandstone interbeds, *D*, cap local areas and exhibit serrated margins as a result of closely spaced joints. Fine-textured drainage is typical of the poorly resistant shale and thin sandstone interbeds.



Stereoscopic pair

Approximately 1 mile

FIGURE 84.—FAULTED, GENTLY DIPPING SEDIMENTARY ROCKS (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Conspicuous high-angle faults offset beds in many places, as at *A*, where limestone caprock is down-faulted about 125 feet. Note the effect of vertical exaggeration in the stereoscopic model on the amount of offset. Fault is indicated by scarp, *B*, and its alinement with stream at *C*. Note right-angle bend in stream at *D* along trace of fault. Another fault is indicated by alinement of stream *E* and break in vegetation *F*. Several other faults with only small displacements are shown by alinements at *G*. Resistant limestone caprock stands in vertical bluffs overlying less resistant shale and shaly siltstone that have a lesser angle of slope.

FIGURE 85.—VEGETATED TERRAIN UNDERLAIN BY IGNEOUS AND METAMORPHIC ROCKS LOCALLY COVERED BY BASALT FLOWS (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

A significant contrast between the igneous and metamorphic complex and younger volcanic flows is shown in the distribution of faults and vegetation. Faults, indicated primarily by rectilinear depressions, *A*, are common in the igneous and metamorphic rocks, but are absent from the area of lava flows, *B*. Note that certain faults, as at *C*, may be traced up to the lava flows and that continuations of these faults may be picked up on the opposite side of the flow area. Some of the shorter lineations, as at *D*, probably represent wide-spaced joints. Lobate patterns of dark-toned vegetation, *E*, commonly delineate the edges of individual lava flows. Small cone at *F* is suggested by shape of constructional landform. Relatively flat, muskeg-covered flows are generally poorly drained and locally contain numerous shallow ponds, *G*, that lack any integrated drainage. The muskeg areas have a relatively light photographic tone because of the mossy vegetation and do not appear dark despite the abundance of moisture. The photographic texture of the muskeg areas is also distinctive.

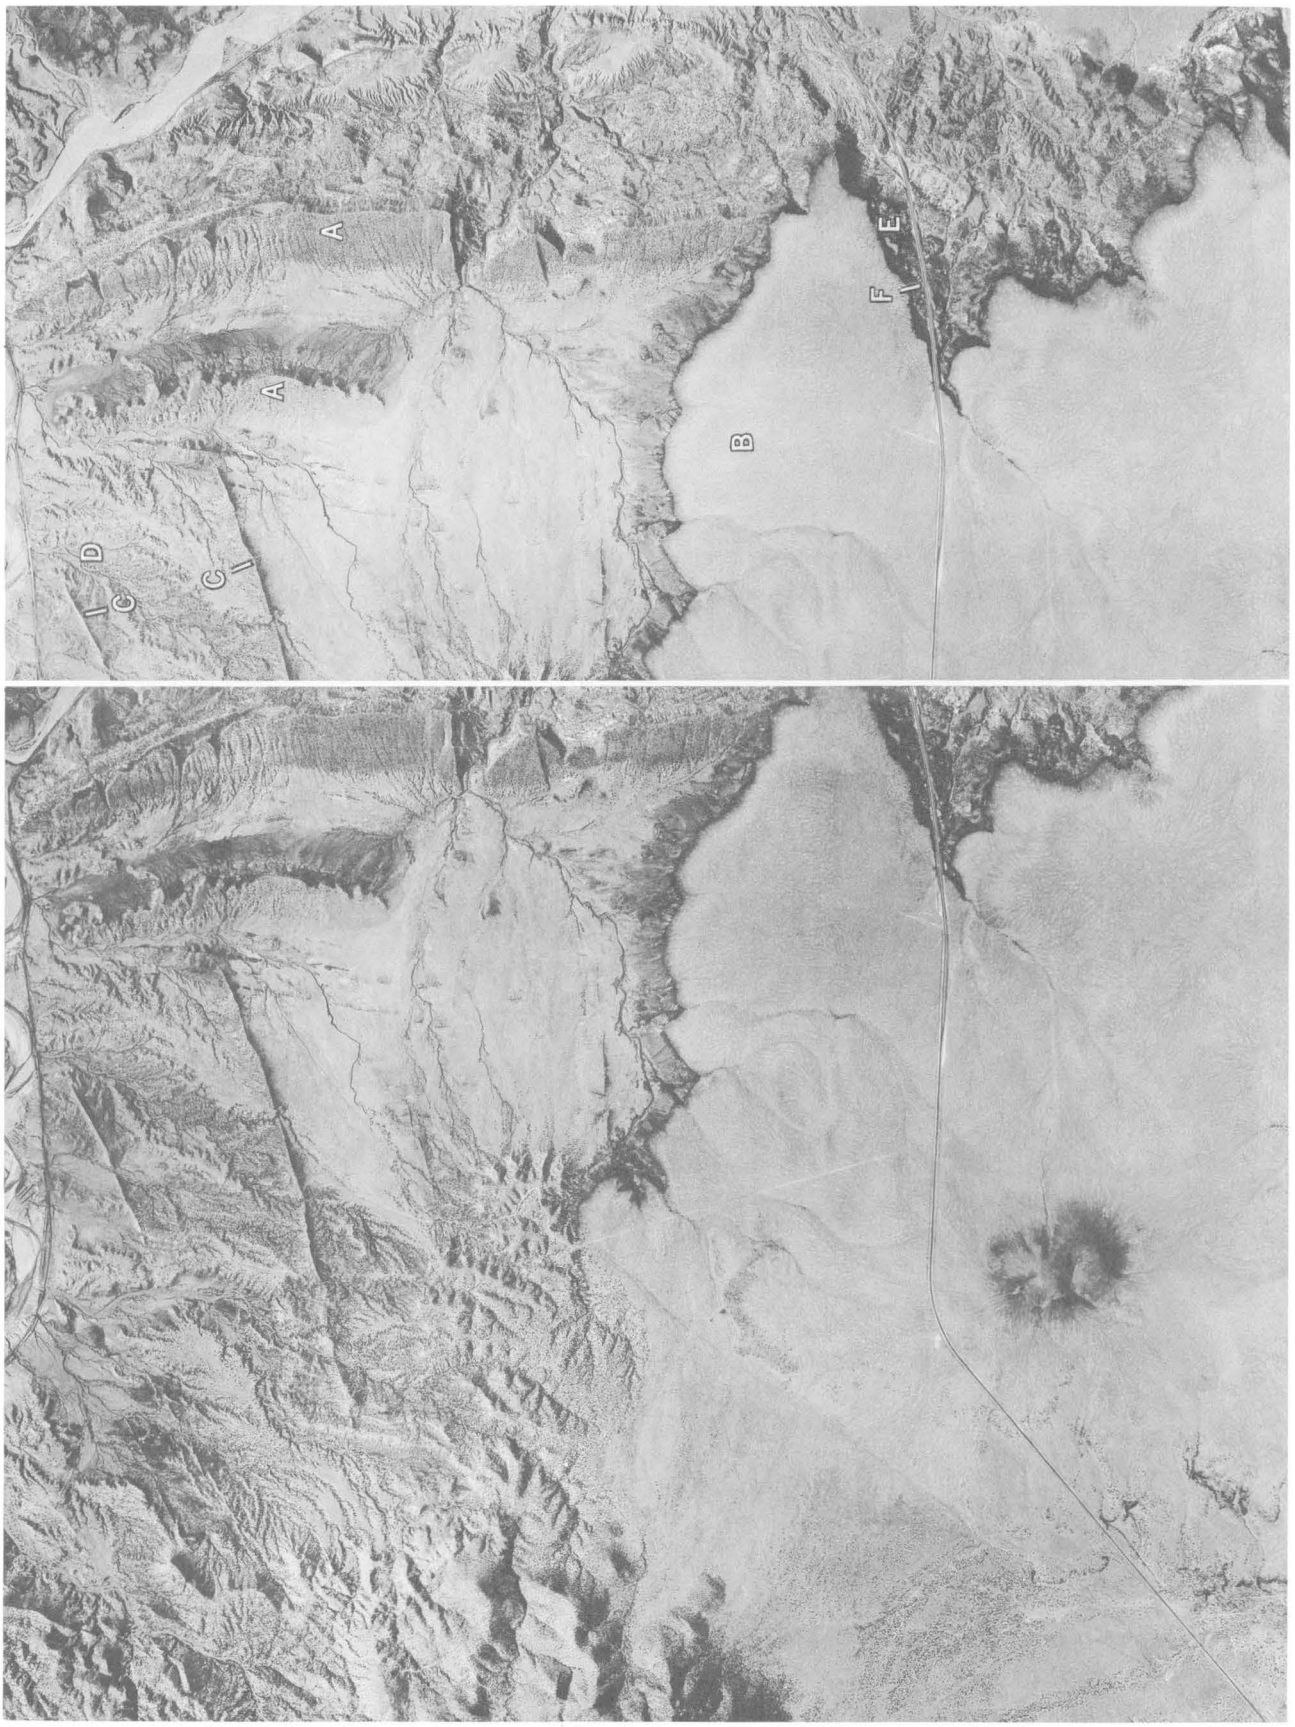
Approximately 1 mile

553966 O-60—8

FIGURE 86.—AREA OF CRYSTALLINE ROCKS (WYOMING).

[Approximate scale 1 : 60,000. Photographs by Army Map Service]

Numerous widely spaced joints, typical of many intrusive masses, are conspicuous, although widely varying orientations of joints, found in most plutonic rocks, are not prominent. Drainage is markedly controlled by faults and joints; the dendritic drainage that is normally characteristic of crystalline masses is thus subdued. Although the rocks shown here are locally gneissic, evidence of bedding of original sediments or gneissic structure is generally lacking. Major fault, *A*, marked by stream alinement, is offset by younger fault, *B*, also delineated by stream alinement. Note alinement of streams on opposite side of divide, *C*.



Stereoscopic pair

Approximately 1 mile

FIGURE 87.—LAVA FLOW LYING UNCONFORMABLY ON GENTLY DIPPING SEDIMENTARY ROCKS (NEW MEXICO).

[Approximate scale 1 : 54,000. Photographs by Army Map Service]

Resistant sandstone beds, *A*, dipping 15° are truncated by overlying lava flow, *B*. Bedding stands out where topographic and bedding surfaces coincide. Hogback landform is also prominent where resistant sandstone beds and intervening shale areas have been etched by erosion. Note how vertical exaggeration of dip causes unconformable relation between sedimentary beds and overlying lava flow to stand out. Surface of lava flow has mottled appearance that is typical of basalt flows in many areas. Basaltic dikes, *C*, stand in topographic relief above soft shale shown by fine-textured drainage at *D*. Some landsliding has taken place at *E* where resistant lava overlies less resistant rocks. Road alinement *F* is subject to potential destructive action of additional slides.

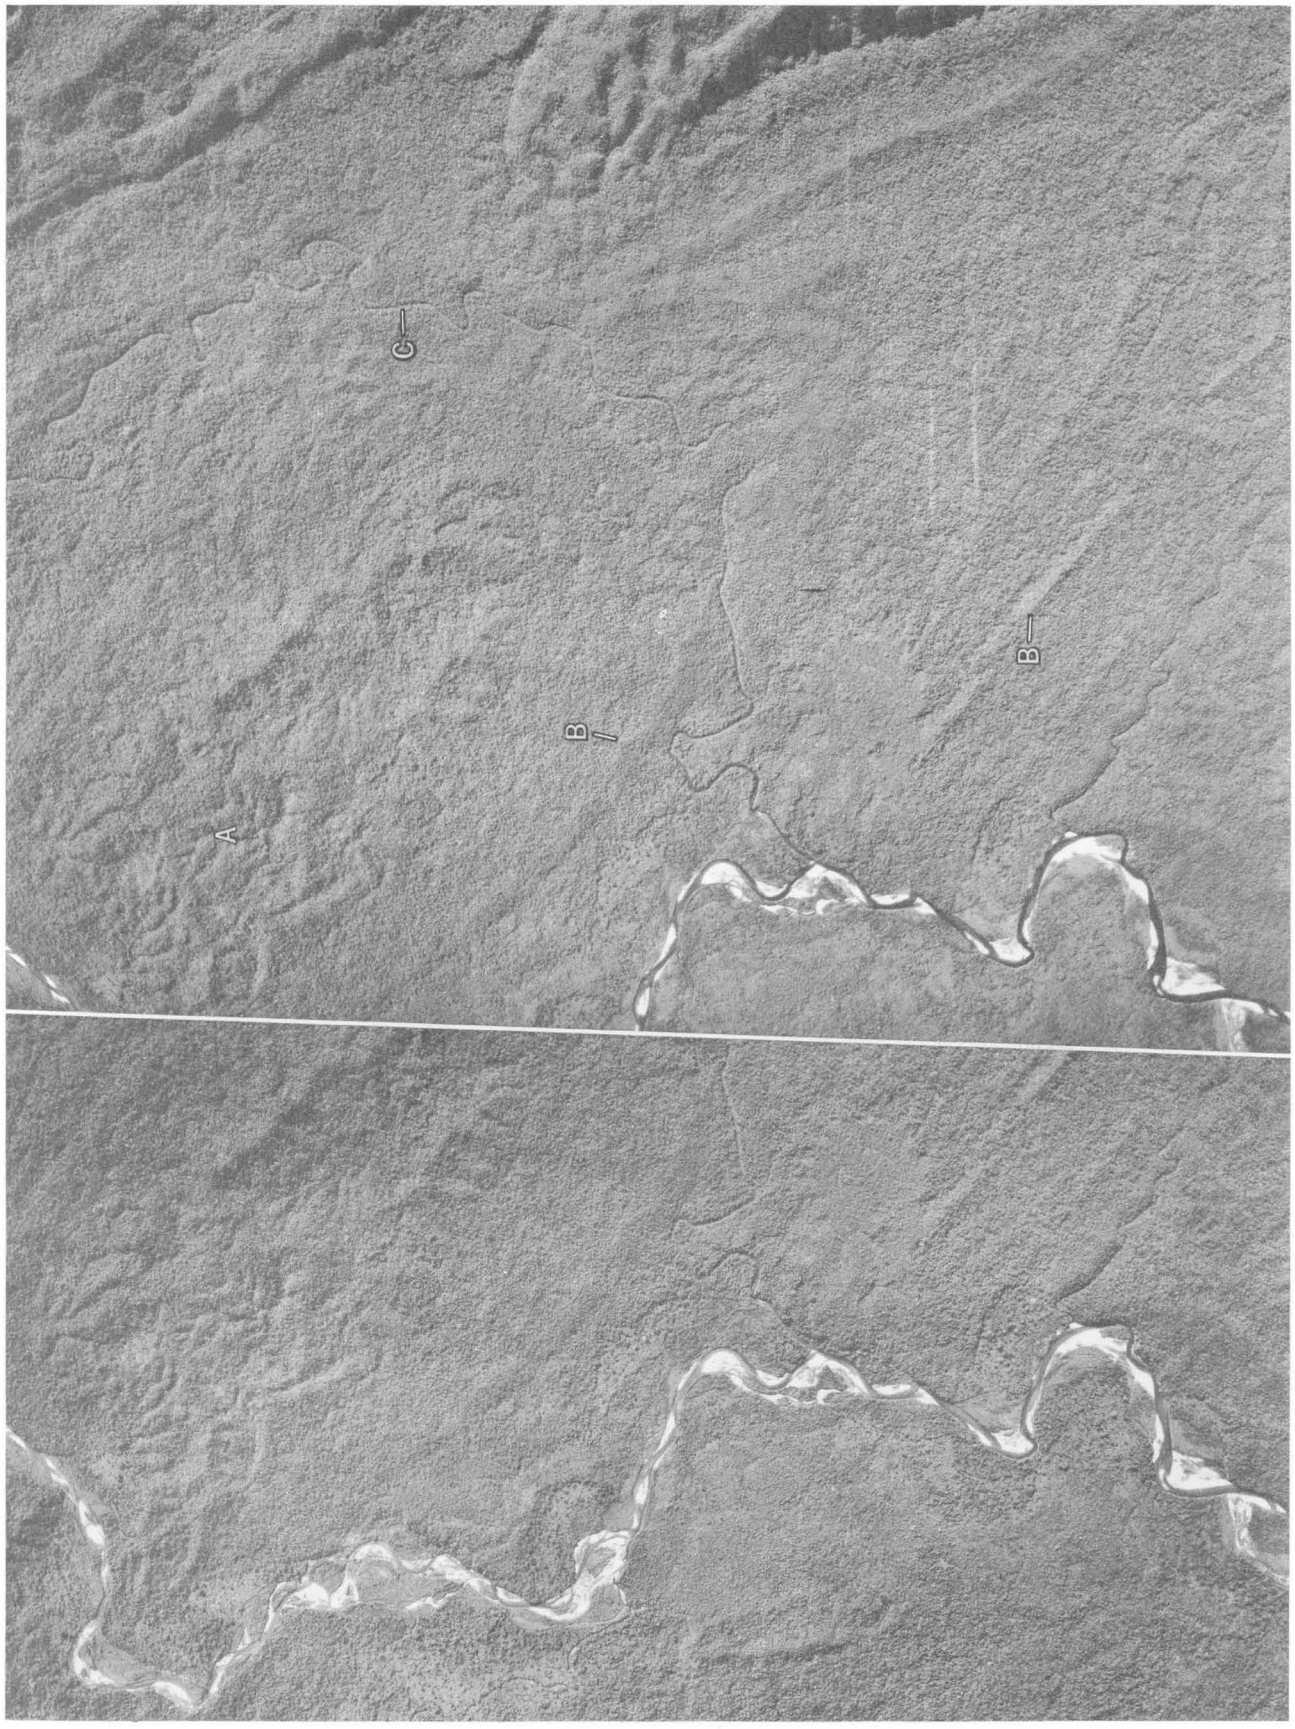
FIGURE 88.—GENTLY DIPPING SEDIMENTARY ROCKS OVERLAIN IN PART BY RIVER GRAVELS (UTAH).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Flat-lying gravel cap, *A*, truncates underlying sedimentary rocks. Traces of bedding below granular material of gravel cap are indicated by minor breaks in slope, *B*, accentuated by shadows. Surface drainage is conspicuously absent from well-drained broad gravel flat, *D*, which represents a younger, lower and less dissected terrace than *A*. Gullies in silty valley-fill, *E*, exhibit near-vertical slopes where recent stream dissection has taken place. Note effect of vertical exaggeration in the stereoscopic model. True dip of beds at *C* is about 6°.



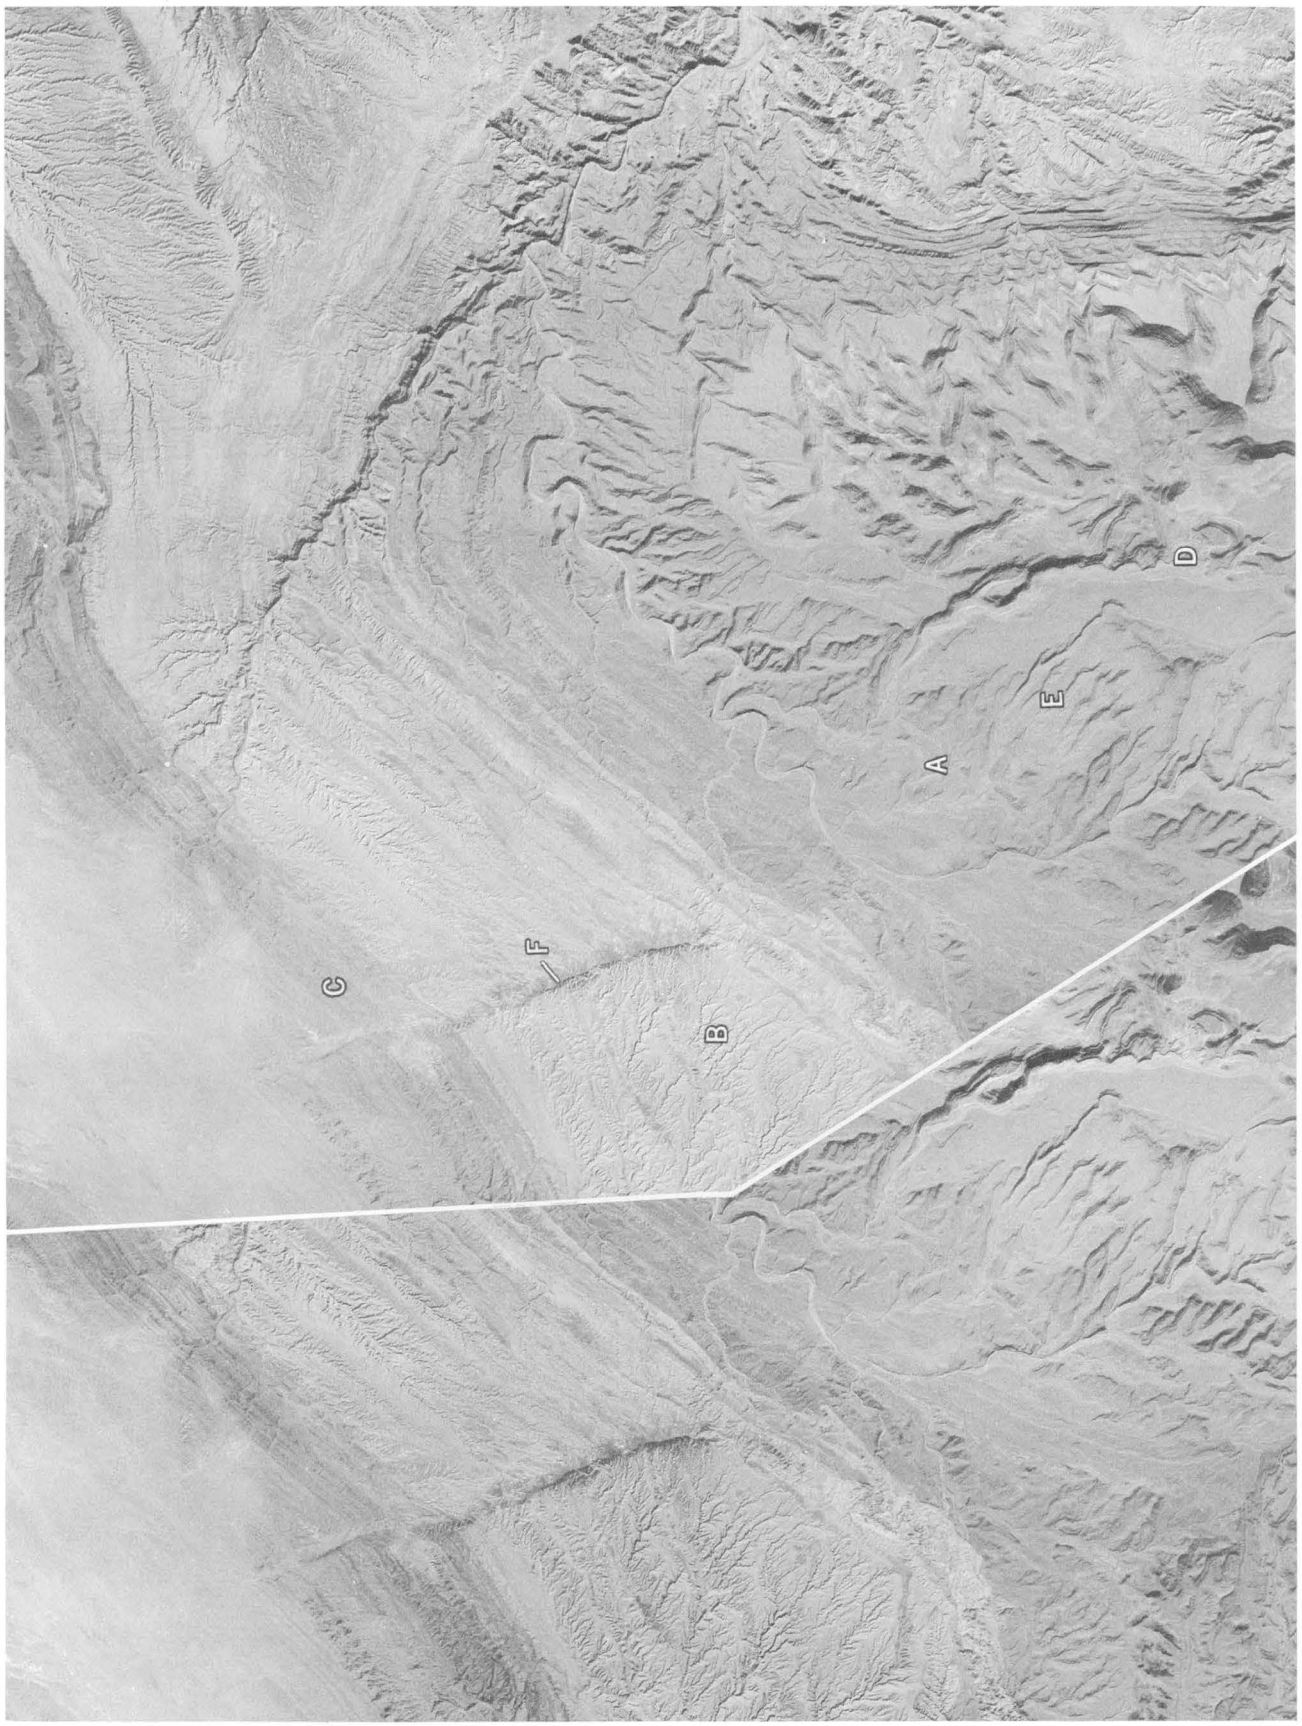
Stereoscopic pair

Approximately 1 mile

FIGURE 89.—GENTLY FOLDED SEDIMENTARY ROCKS IN HEAVILY VEGETATED AREA (NORTHERN GUATEMALA).

[Approximate scale 1 : 65,000. Photographs by Army Map Service; published with permission of the Guatemala Government]

Anticlinal structural feature in heavily vegetated jungle area is indicated by erosional characteristics of terrain and by drainage. Core of anticline, *A*, is topographically higher than surrounding area and is somewhat more dissected. Bedding and direction of dip are suggested by the topographically high bands of ground at *B*; note that tree crowns appear to fall in a dipping plane. Stream, *C*, has been deflected around the nose of the anticline; the convex side of the curve indicates the direction of plunge, but the major stream of the area has maintained its course across the anticline.



Stereoscopic pair

Approximately 1 mile

FIGURE 90.—PLUNGING ANTICLINE IN GENTLY FOLDED ROCKS (SOUTHERN UTAH).

[Approximate scale 1 : 37,000. Photographs by U.S. Geological Survey]

Distribution of rock types and characteristics of drainage clearly outline plunging anticline. Note that major stream curves around nose of the anticline and the convex side of the curve indicates the direction of plunge. Lithologic differences between formations are conspicuously shown by contrasts in photographic tone and erosional characteristics of terrain. Dark-toned formation, *A*, is an interbedded sequence predominantly of red sandstone and some mudstone and shale. Light-toned formation, *B*, is made up of a rather uniform weakly cemented massively bedded sandstone showing a fine-textured dendritic drainage. Drainage rills in formation *A* and *C* are controlled in part by hard, resistant sandstone interbeds that locally channel the drainage along the interbeds. Formation *C* largely comprises a series of red to brown silty sandstone and shale. Rocks at *D* include predominantly thin-bedded red sandstone and limestone interbeds. Bedding is prominently shown because topographic surfaces and bedding surfaces coincide in many places. Dip of sedimentary beds is exaggerated as in most stereoscopic models. True dip at *E* is 5°. Dark-toned resistant basalt dike, *F*, stands in relief above light-toned rocks.

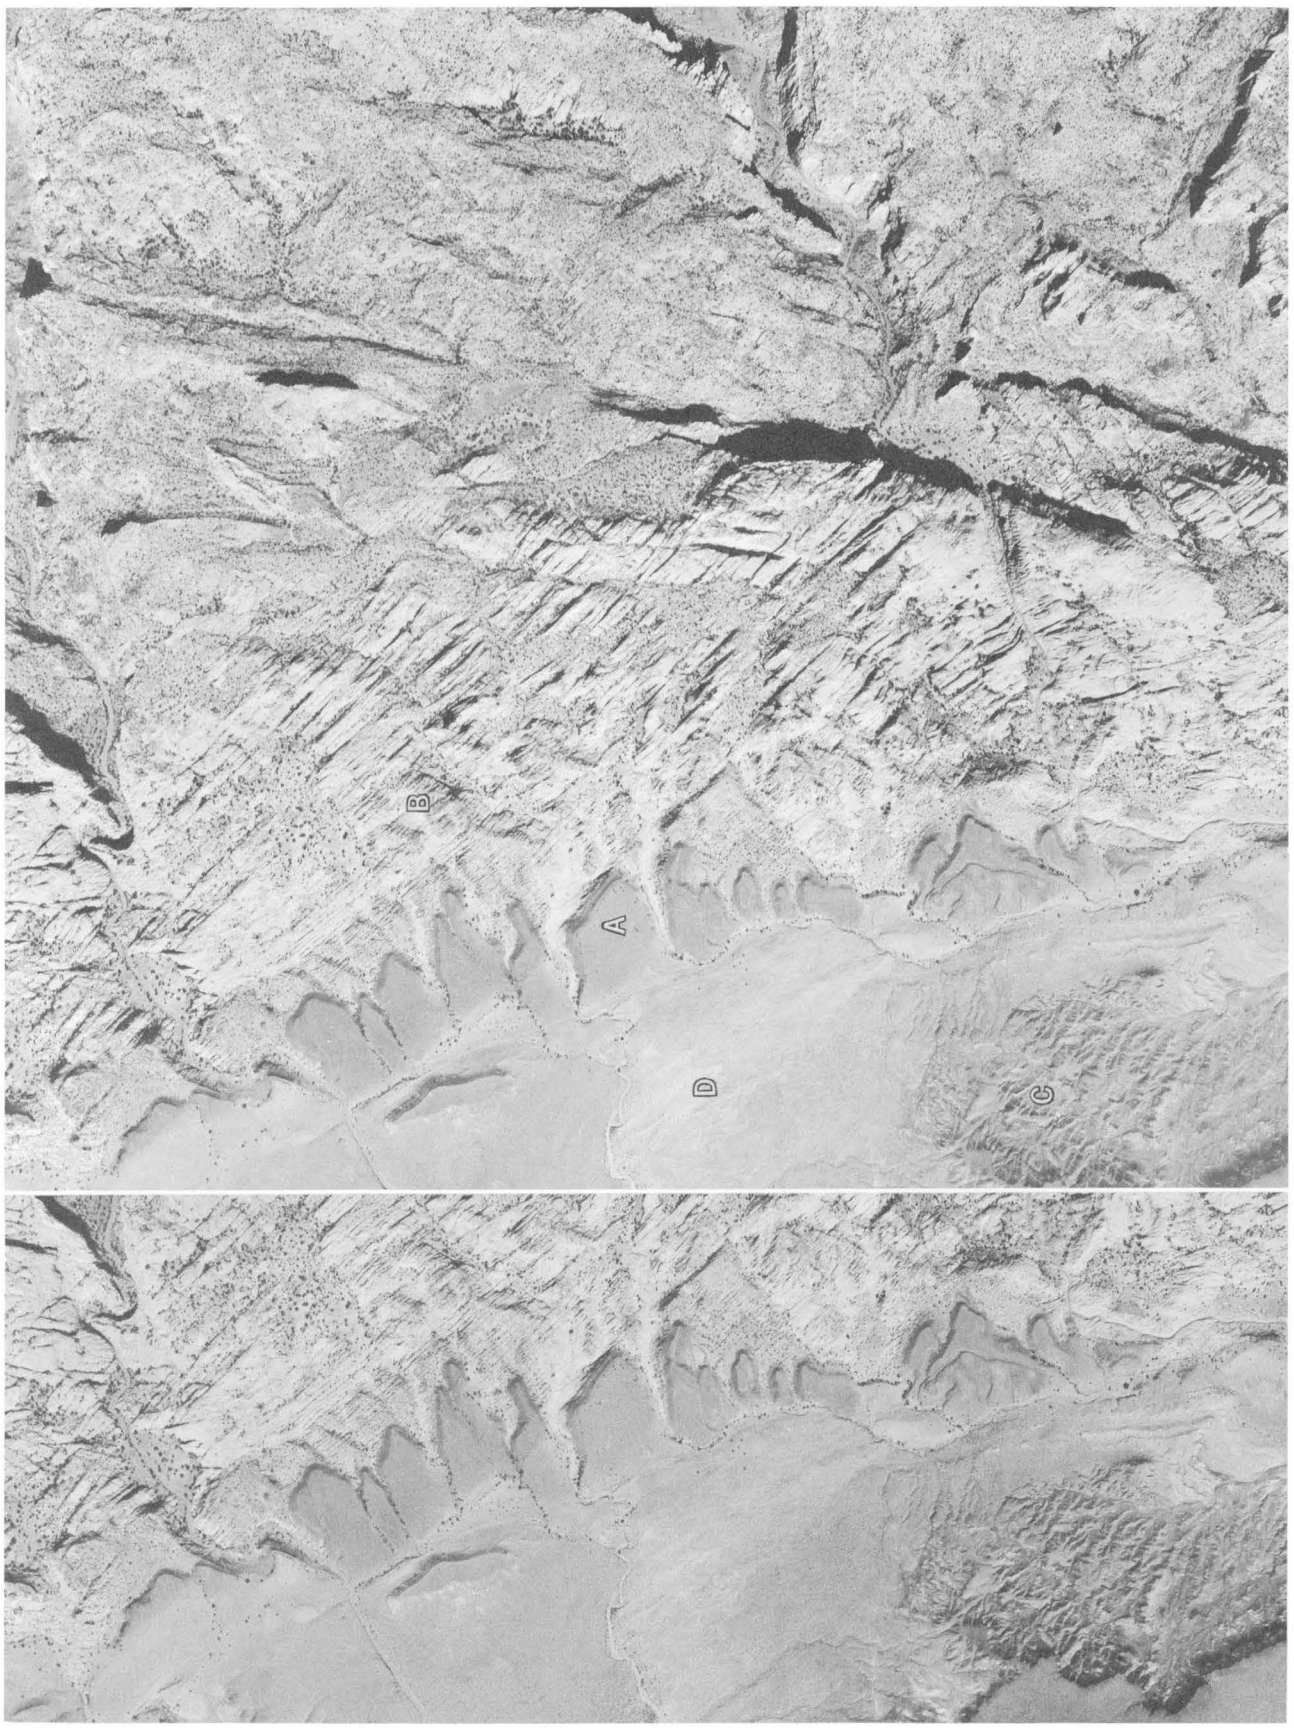
FIGURE 91.—STRATIGRAPHIC SECTION ACROSS GENTLY FOLDED ANTICLINE (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Breaching of anticline by major river has exposed cross section of the fold. Bedding is clearly represented at *A* where bedding surfaces coincide with topographic surfaces. Effect of vertical exaggeration on dip is shown on both flanks of the anticline. True dip at *A* is about 20°; at *B* the beds are horizontal; at *C* the dip is about 4°. Shale, siltstone, and fine-grained sandstone, *D*, exhibit dark photographic tones; relatively closely spaced joints may be seen locally. Coarse sandstone with some conglomerate, *E*, has light photographic tone; widely spaced joints are present as at *F*. The coarse-grained rocks characteristically form cliffs. Where beds are nearly horizontal the fine-grained rocks have slopes that are less steep than those of the coarse-grained rocks. Where beds are dipping, the softer rocks are in many places etched out by erosion leaving hogbacks of resistant rock types.



Stereoscopic pair

Approximately 1 mile

FIGURE 92.—GENTLY DIPPING SEDIMENTARY ROCKS ON EAST SIDE OF SAN RAFAEL SWELL (UTAH).

[Approximate scale 1 : 20,000. Photographs by U.S. Geological Survey]

Bedding on flank of fold is clearly shown by photographic tone differences and hogback landform where dip surfaces and topographic surfaces coincide. Note effect of vertical exaggeration on dip in the stereoscopic model; beds at *A* have true dip of 6°. Massive crossbedded sandstone, *B*, has light photographic tone and widely spaced joints oriented predominantly in one direction; locally its appearance on aerial photographs is similar to some igneous rocks. Dark-toned resistant beds, *A*, are red mudstone and lenticularly bedded medium-grained sandstone. Poorly resistant interbedded red limy sandstone, mudstone, and limestone, *C*, is easily eroded and has fine-textured drainage. Beds at *C* are flat lying. Windblown sand, *D*, is marked by absence of surface drainage channels.

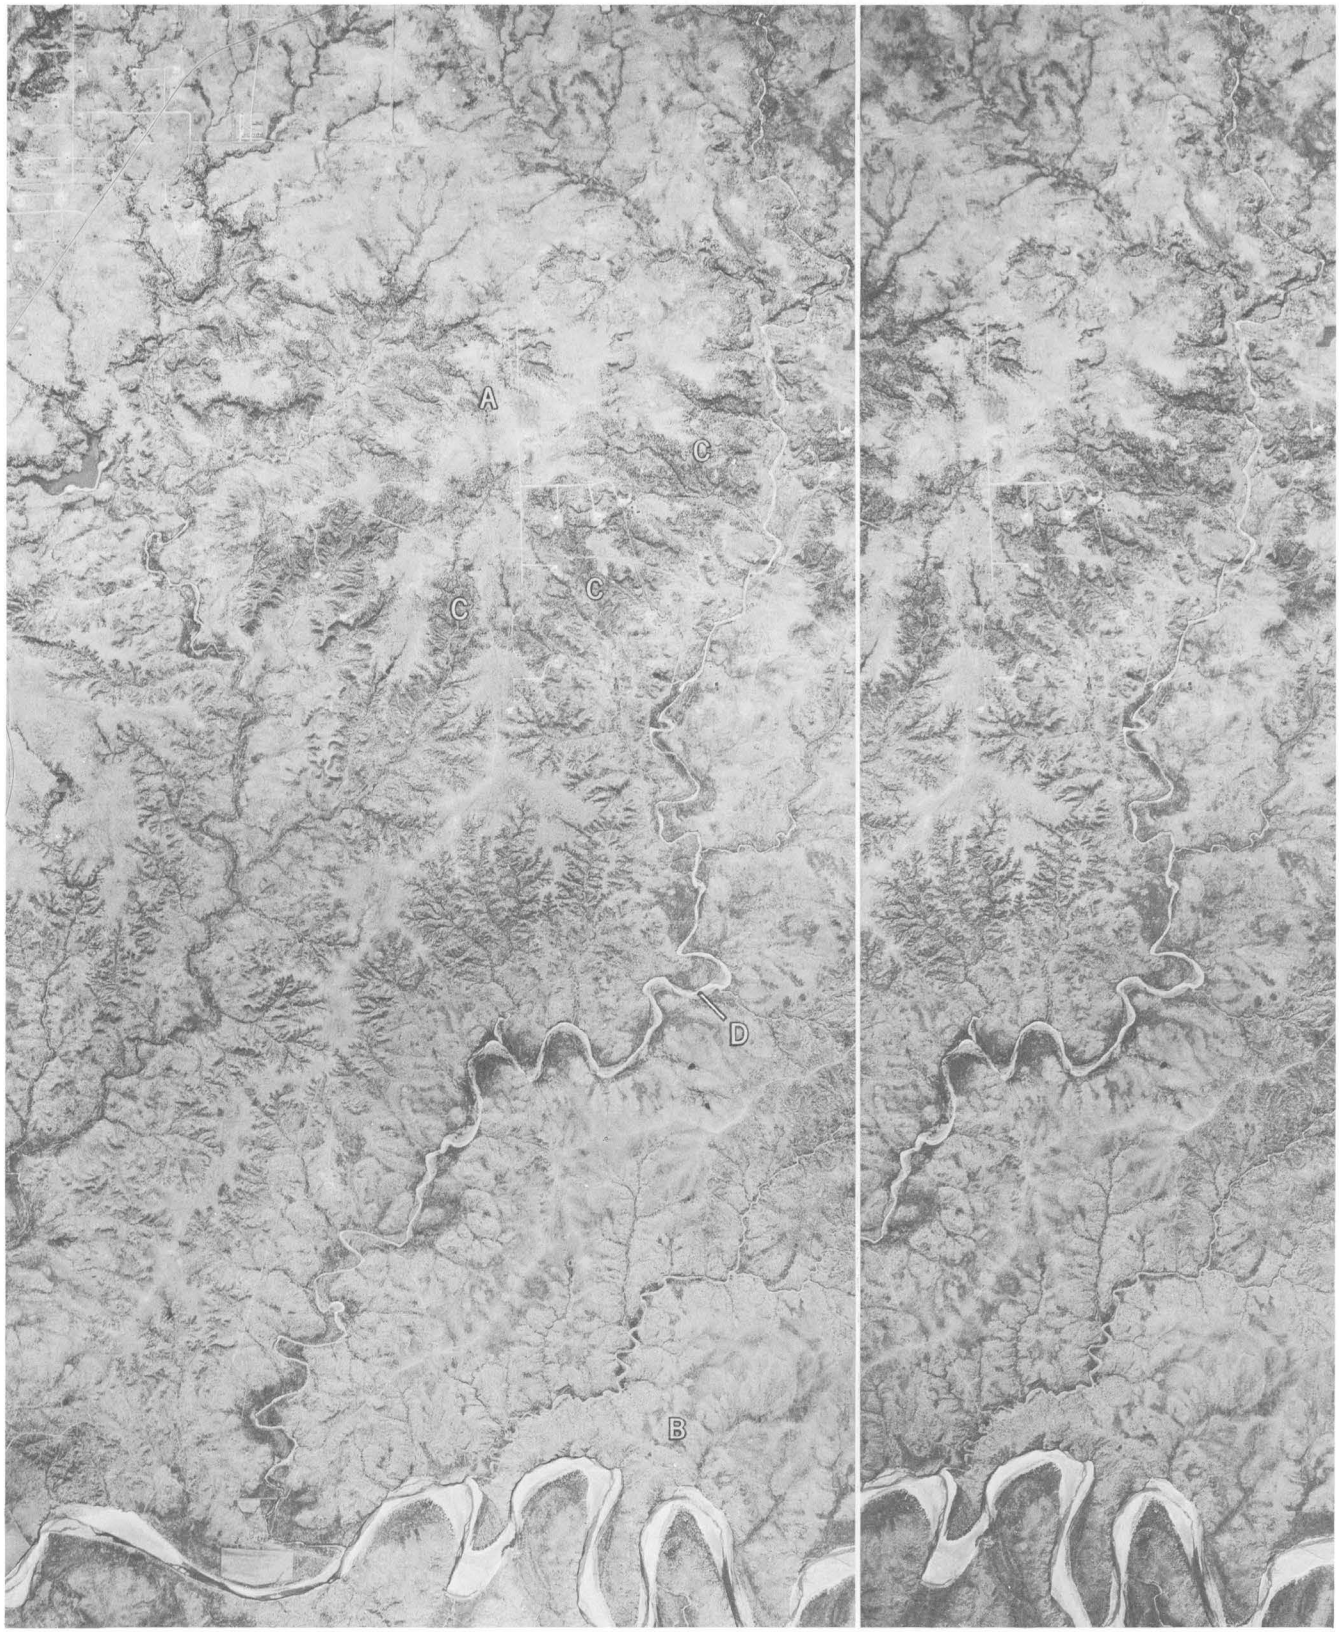
FIGURE 93.—UNCONTROLLED MOSAIC OF UMIAT ANTICLINE AREA, NORTHERN ALASKA, UNDERLAIN BY SHALE, SANDSTONE, CONGLOMERATE, AND GRAYWACKE.

[Photographs by U.S. Navy]

Curvature of streams, *A*, has developed on flank of anticline where hard and soft interbeds are exposed. Anticline has been breached into soft shale permitting streams developed on the more resistant dip slope to curve along soft interbeds and not across the axis of the fold. Contrast figure 81 where stream curvature indicates position of structural axis and direction of structural plunge.



Stereoscopic pair

Approximately 1 mile

FIGURE 94.—SUBSURFACE STRUCTURE REFLECTED IN SURFACE DRAINAGE CHARACTERISTICS (TEXAS).

[Approximate scale 1 : 63,360. Photographs by Army Map Service]

Subsurface structures at *A* and *B* are suggested by drainage characteristics of the area. Streams flanking the structure at *A* curve around the structure in their headwater portions. Tributary streams drain radially off the structure (see figures 9 and 95). In addition, the crudely circular pattern of more highly dissected ground and the pattern of dark photographic tone, *C*, which results from a concentration of vegetation, suggest subsurface structure. Compressed meanders are present over a subsurface structure at *B*. Also note stream deflection downstream from *D* which is a further suggestion of subsurface structure in area *B*.

Stereoscopic pair

Approximately 1 mile

FIGURE 95.—SAME PHOTOGRAPHS AS FIGURE 94, BUT REVERSED TO SHOW PSEUDOSCOPIC EFFECT AS AN AID TO INTERPRETATION.

[Approximate scale 1 : 63,360. Photographs by Army Map Service]

Reversal of the positions of two aerial photographs of a stereoscopic pair produces the well-known pseudoscopic effect, in which stream valleys appear as ridges and hills look like depressions. This unnatural view of the terrain commonly accentuates stream characteristics, which may be significant indicators of subsurface structure, as at *A*. The pseudoscopic view also commonly facilitates plotting of drainage.

KUGRUA RIVER
KUNGOK RIVER
N
2 Miles

FIGURE 96.—UNCONTROLLED MOSAIC OF WAINWRIGHT AREA, NORTHWESTERN ALASKA.

[Photographs by U.S. Navy]

The radial-dendritic drainage pattern shown is anomalous to the Arctic coastal plain where northward-flowing streams predominate. Local relief across the area is only a few feet per mile. The radial drainage pattern, suggestive of subsurface structure, is readily seen on the small-scale mosaic but could be easily overlooked on single photographs or individual stereoscopic pairs. Note the northward deflection of the Kugrua River; the abrupt change in direction of streamflow is believed due to subsurface structure. Seismic work indicates a structural nose plunging southeast in the north-central part of the area. Outcrops are sparse in the area and surface indications of structure, other than drainage pattern, are generally lacking. The drainage pattern of this area is similar to that of an area to the southeast where gas was found in a subsurface structure that had been defined by geophysical methods.

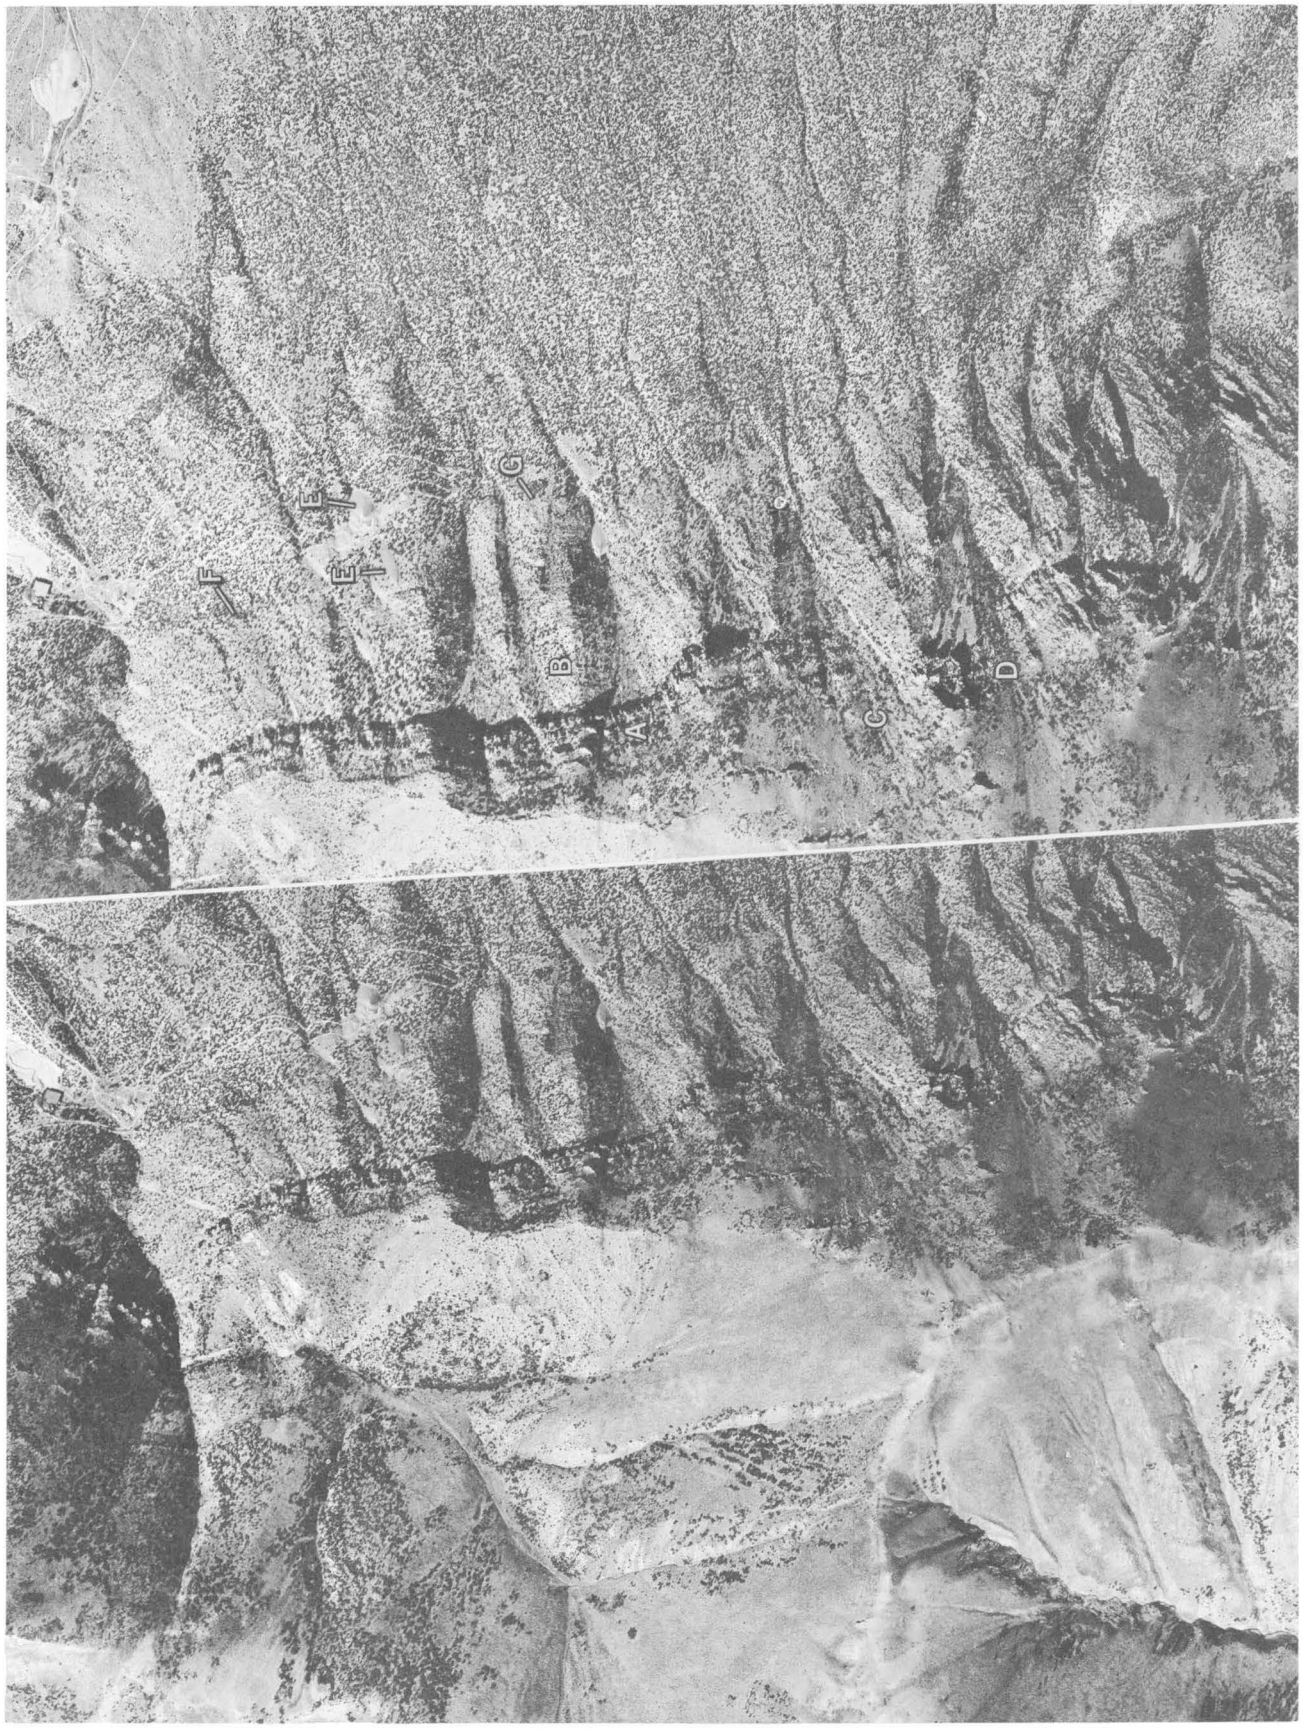
Stereoscopic pair

Approximately 1 mile

FIGURE 97.—AREA UNDERLAIN PREDOMINANTLY BY GENTLY DIPPING SANDSTONE AND SHALE (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

Sandstone beds stand out because of photographic tone, relief, and vegetation changes, as at *A*. As these sandstone beds are traced across the area they lose their topographic expression, as at *B*, and are replaced by shale of the underlying formation. The rate of "shaling" or change of facies from sandstone to shale can be calculated from quantitative studies of the aerial photographs, and the direction of maximum thinning of the sandstone section determined. Note the effect of vertical exaggeration on dip of resistant sandstone beds; true dip is 7° to 8° in this area. Effect of vertical exaggeration is also shown at *C* where minor topographic breaks in slope, accentuated by shadows, reflecting thin resistant beds stand out.



Stereoscopic pair

Approximately 1 mile

FIGURE 99.—COMPLEXLY FOLDED AND FAULTED AREA OF GREENSTONE, SCHIST, LIMESTONE AND MARBLE (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

Relatively dark-toned highly fractured rocks, *A*, are greenstone and greenstone schist. Light-toned profusely fractured rocks, *B*, are limestone and marble. Prominent lineations, *C*, are representative of faults along which rich gold-quartz veins have been found in this area. Note that fault lineations characteristically are rectilinear depressions.

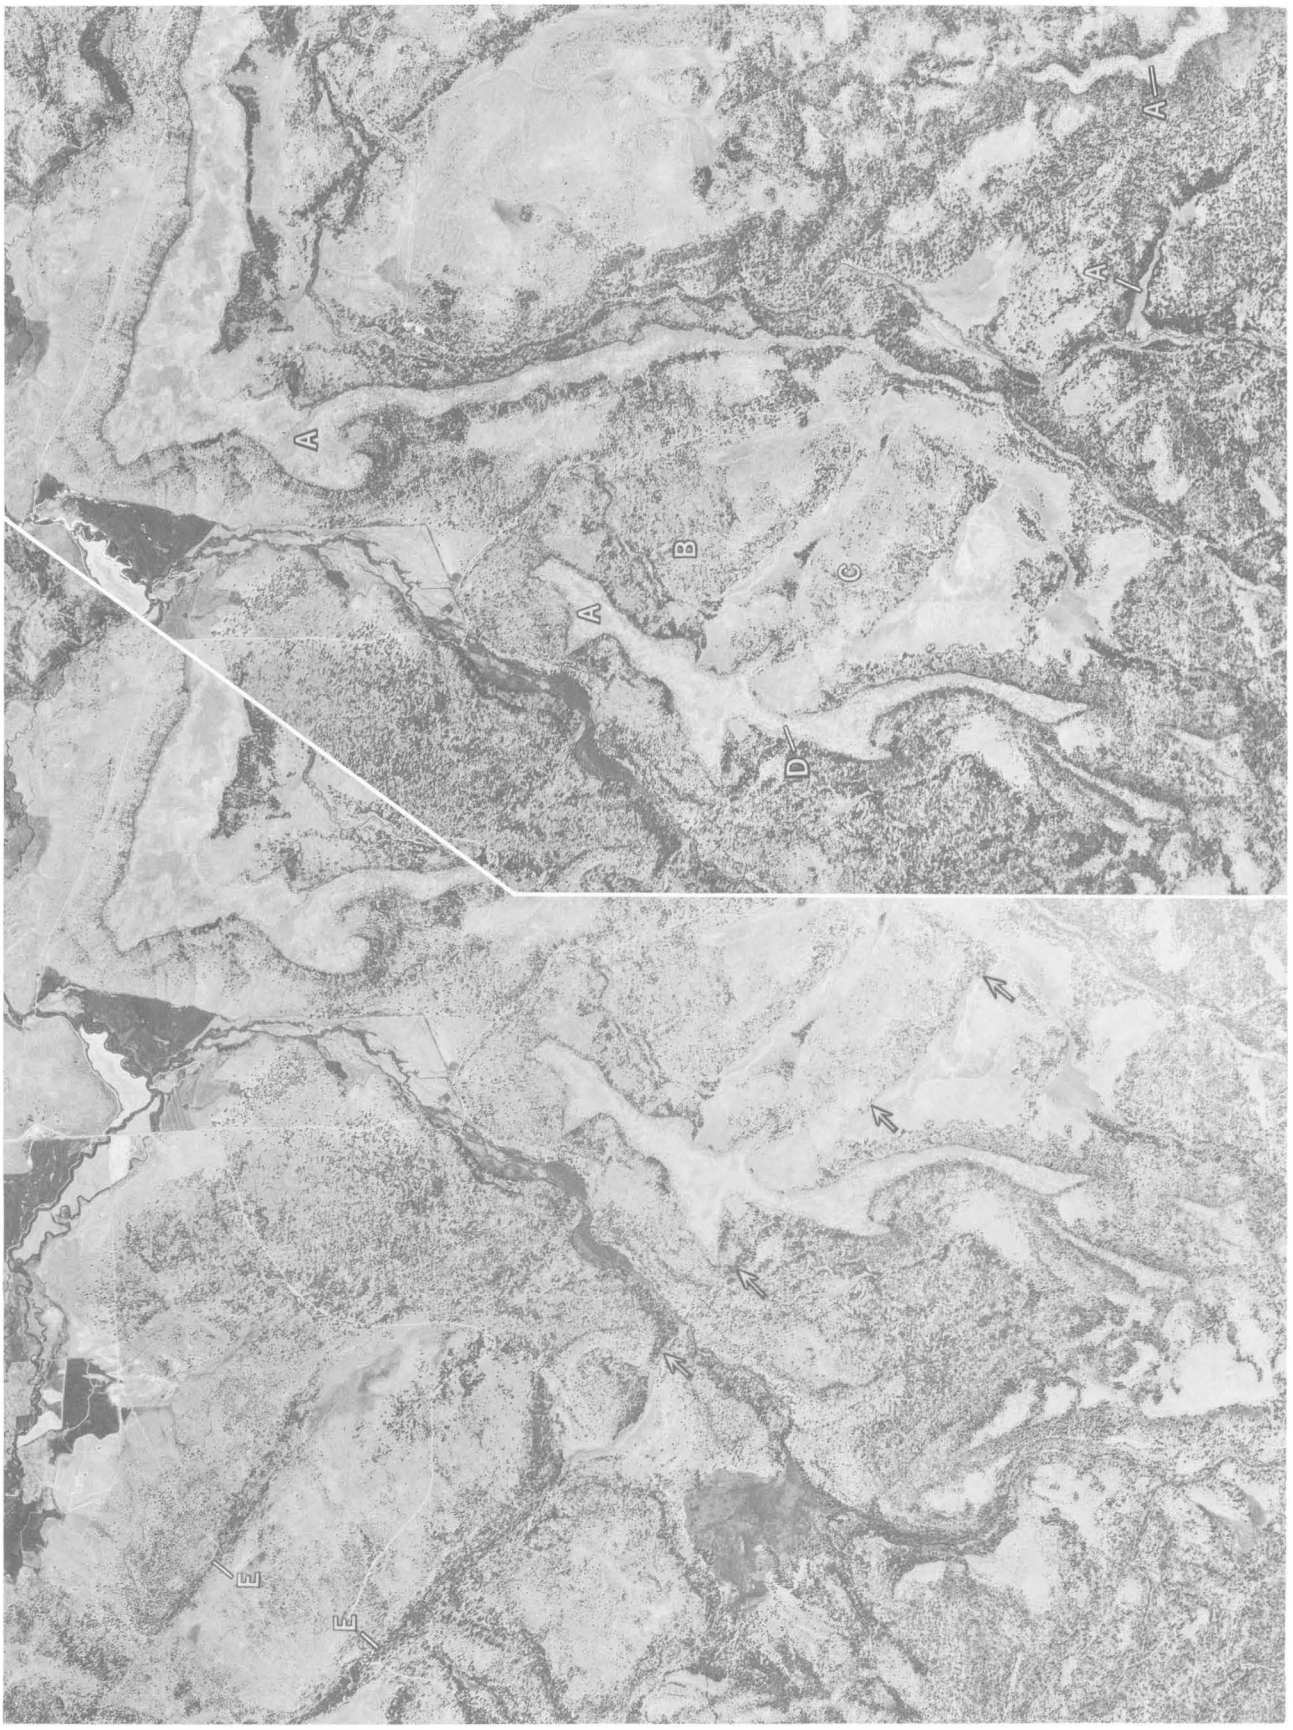
Stereoscopic pair

Approximately 1 mile

FIGURE 100.—IGNEOUS AND METAMORPHIC TERRAIN (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

In this area lead and silver deposits are found locally along the contact of intrusive quartz diorite and metamorphic rocks. Smooth slopes, *A*, are underlain by metamorphic rocks. The closely spaced parallel ridges and depressions, *B*, reflect foliation in the metamorphic rocks. Depressions, *C*, probably represent solution cavities in carbonate interbeds. Lineations, *D*, transecting the foliation direction are believed to be expressions of faults. The uneven surface, *E*, cut by a crisscross of joints is underlain by quartz diorite. This pattern of lines representing joints is typical, but not necessarily diagnostic, of intrusive rocks. The contact of igneous and metamorphic rocks is in the conspicuous saddle between *A* and *E*.



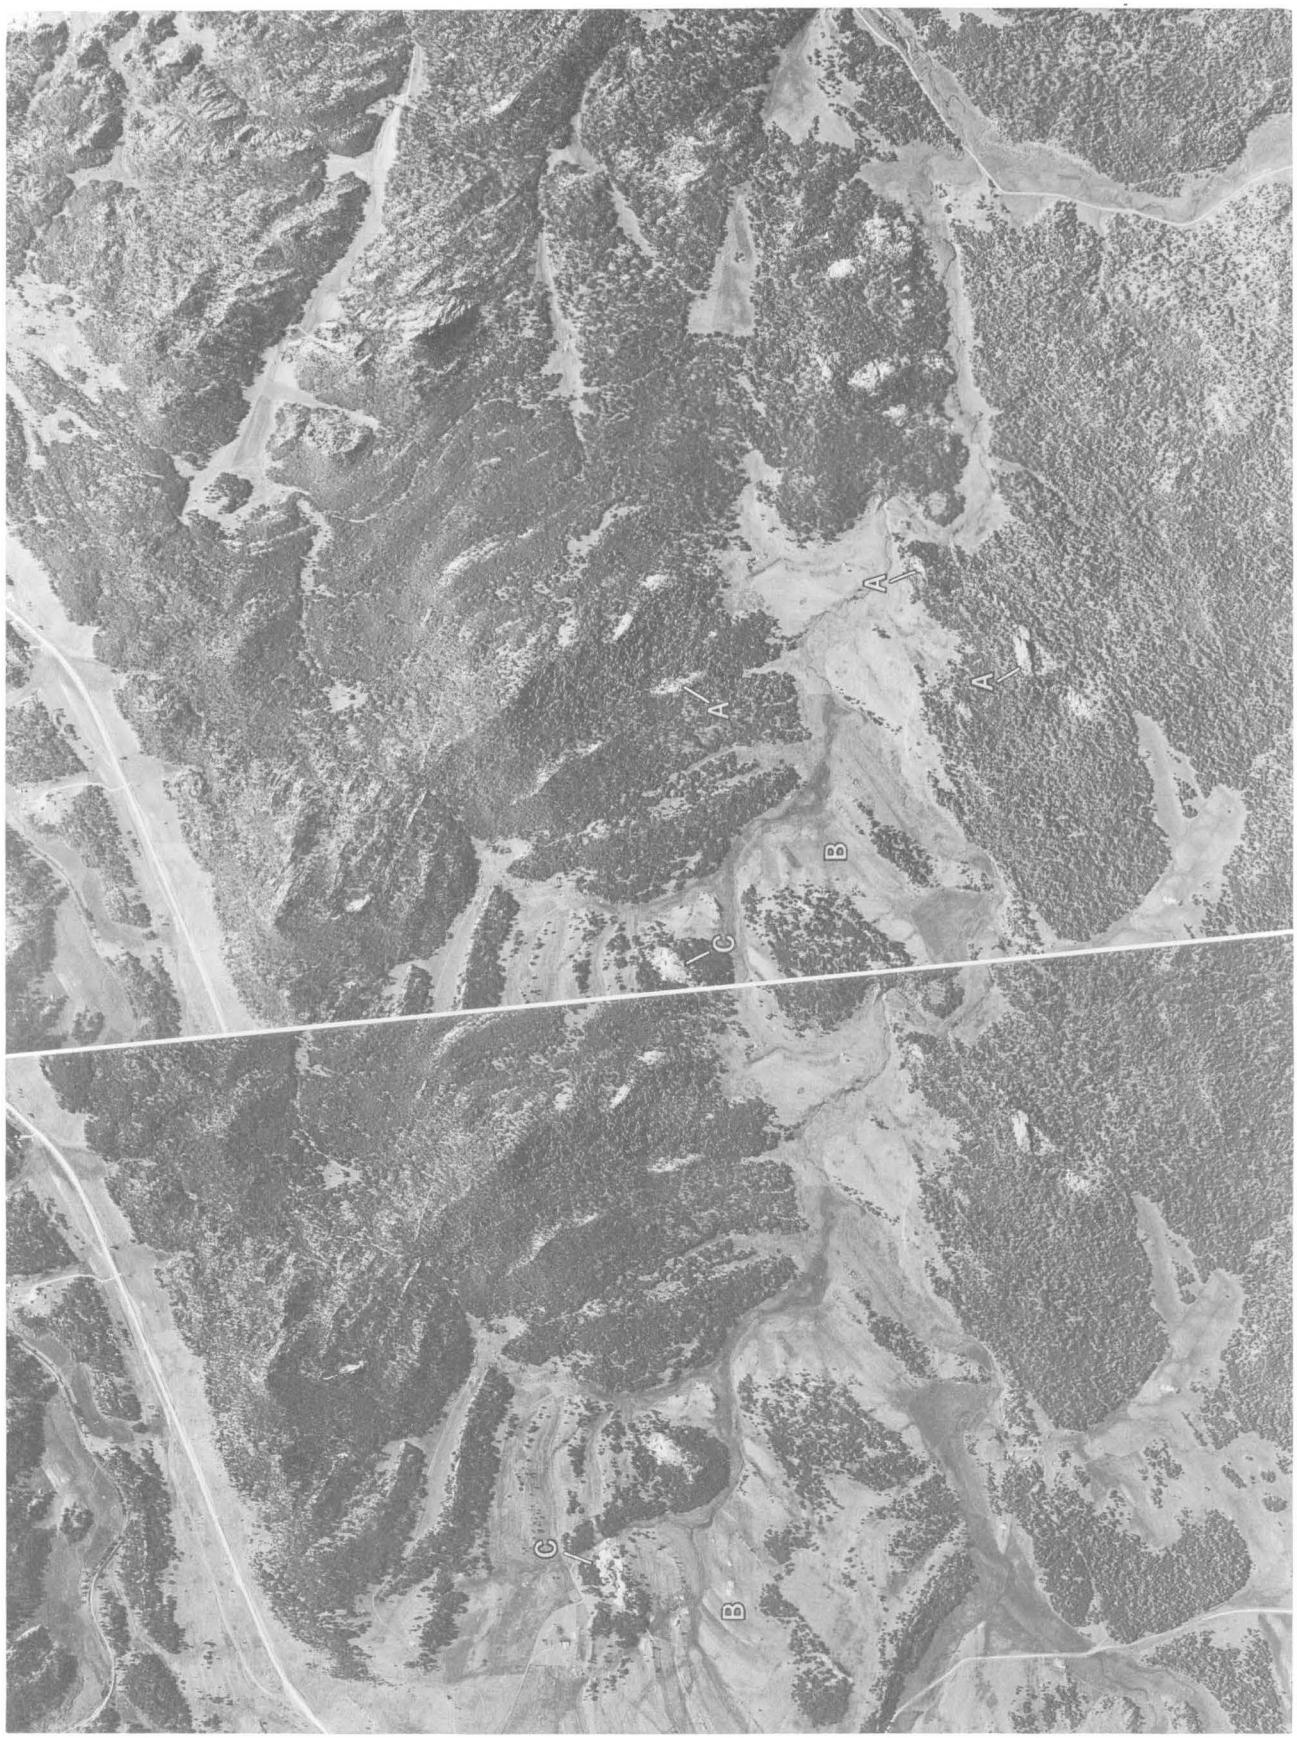
Stereoscopic pair

Approximately 1 mile

FIGURE 101.—GENTLY TILTED AND FAULTED LAVA FLOWS (OREGON).

[Approximate scale 1 : 54,000. Photographs by Army Map Service]

Perched remnants of basaltic lava, *A*, form skeletal dendritic pattern, which suggests that lava filled former stream valleys. In some areas perched lava remnants are known to cover older auriferous stream gravel. Several faults are indicated by alinements of stream segments, vegetation lines, and photographic tone contrasts (see alinement of arrows). Dip on flow surfaces, as at *B*, may be readily estimated or measured from aerial photographs because of the relatively large area examined in a single view, and because of vertical exaggeration of the dip slope. Note that the younger flow, *A*, has a gentler dip than the older flows, *B* and *C*. Surfaces *B* and *C* may be correlative and separated by a fault in the intervening valley. At point *D* the younger perched lava flows are also faulted, but throw is considerably less than where older lava flows are displaced by the same fault. In some areas faults displace only the older rocks and do not offset the most recent flows. A long period of fault activity is thus suggested. Note that in monoscopic view fault alinements, *E*, accentuated by vegetation, are striking.



Stereoscopic pair

Approximately 1 mile

FIGURE 102.—AREA OF PEGMATITE DIKES (SOUTH DAKOTA).

[Approximate scale 1 : 24,000. Photographs by U.S. Geological Survey]

Pegmatites in the area shown are generally concordant with schistosity and bedding of quartz-mica schist country rock. In many places the pegmatite dikes stand in topographic relief above the surrounding schist, as at *A*. The massive, jointed character of the larger pegmatite dikes is similar to other intrusive rocks and contrasts with the thin-bedded schistose rocks. Thin pegmatite dikes commonly cannot be distinguished in the aerial photographs and only general contact areas can be mapped for most of the wide pegmatite dikes because of the vegetation cover. Locally steeply dipping schist also stands in topographic relief; these rocks can be distinguished by the sheeted character of the outcrops. General structural trends are reflected in topographic expression of parallel ridges and in photographic tones of vegetation in fields, *B*. Note mining activity in pegmatite at *C*.

FIGURE 104.—DISTINCTIVE LANDFORM OF GRAVEL TERRACES ALONG A MAJOR STREAM (NORTHEASTERN UTAH).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

The steplike landform of terraces is conspicuous. Other elements of the soil pattern—vegetation, drainage, and erosional characteristics—provide significant information to the photointerpreter. Absence of surface drainage, as at *A*, suggests well-drained materials. At *A* the material is composed of coarse bouldery gravel that has good internal drainage. Vegetation, *B*, is prominent along edges of upper terrace gravel cap where water emerges from the gravel. Lower terraces, as at *C*, are more continuous and less dissected than the older terraces at higher altitudes, although recent streams in conspicuous V-shaped gullies, *D*, dissect the edge of the terrace. Terrace deposits commonly are favorable reservoirs for ground-water storage; in addition they provide a ready source of some materials used by the construction engineer.

Approximately 1 mile

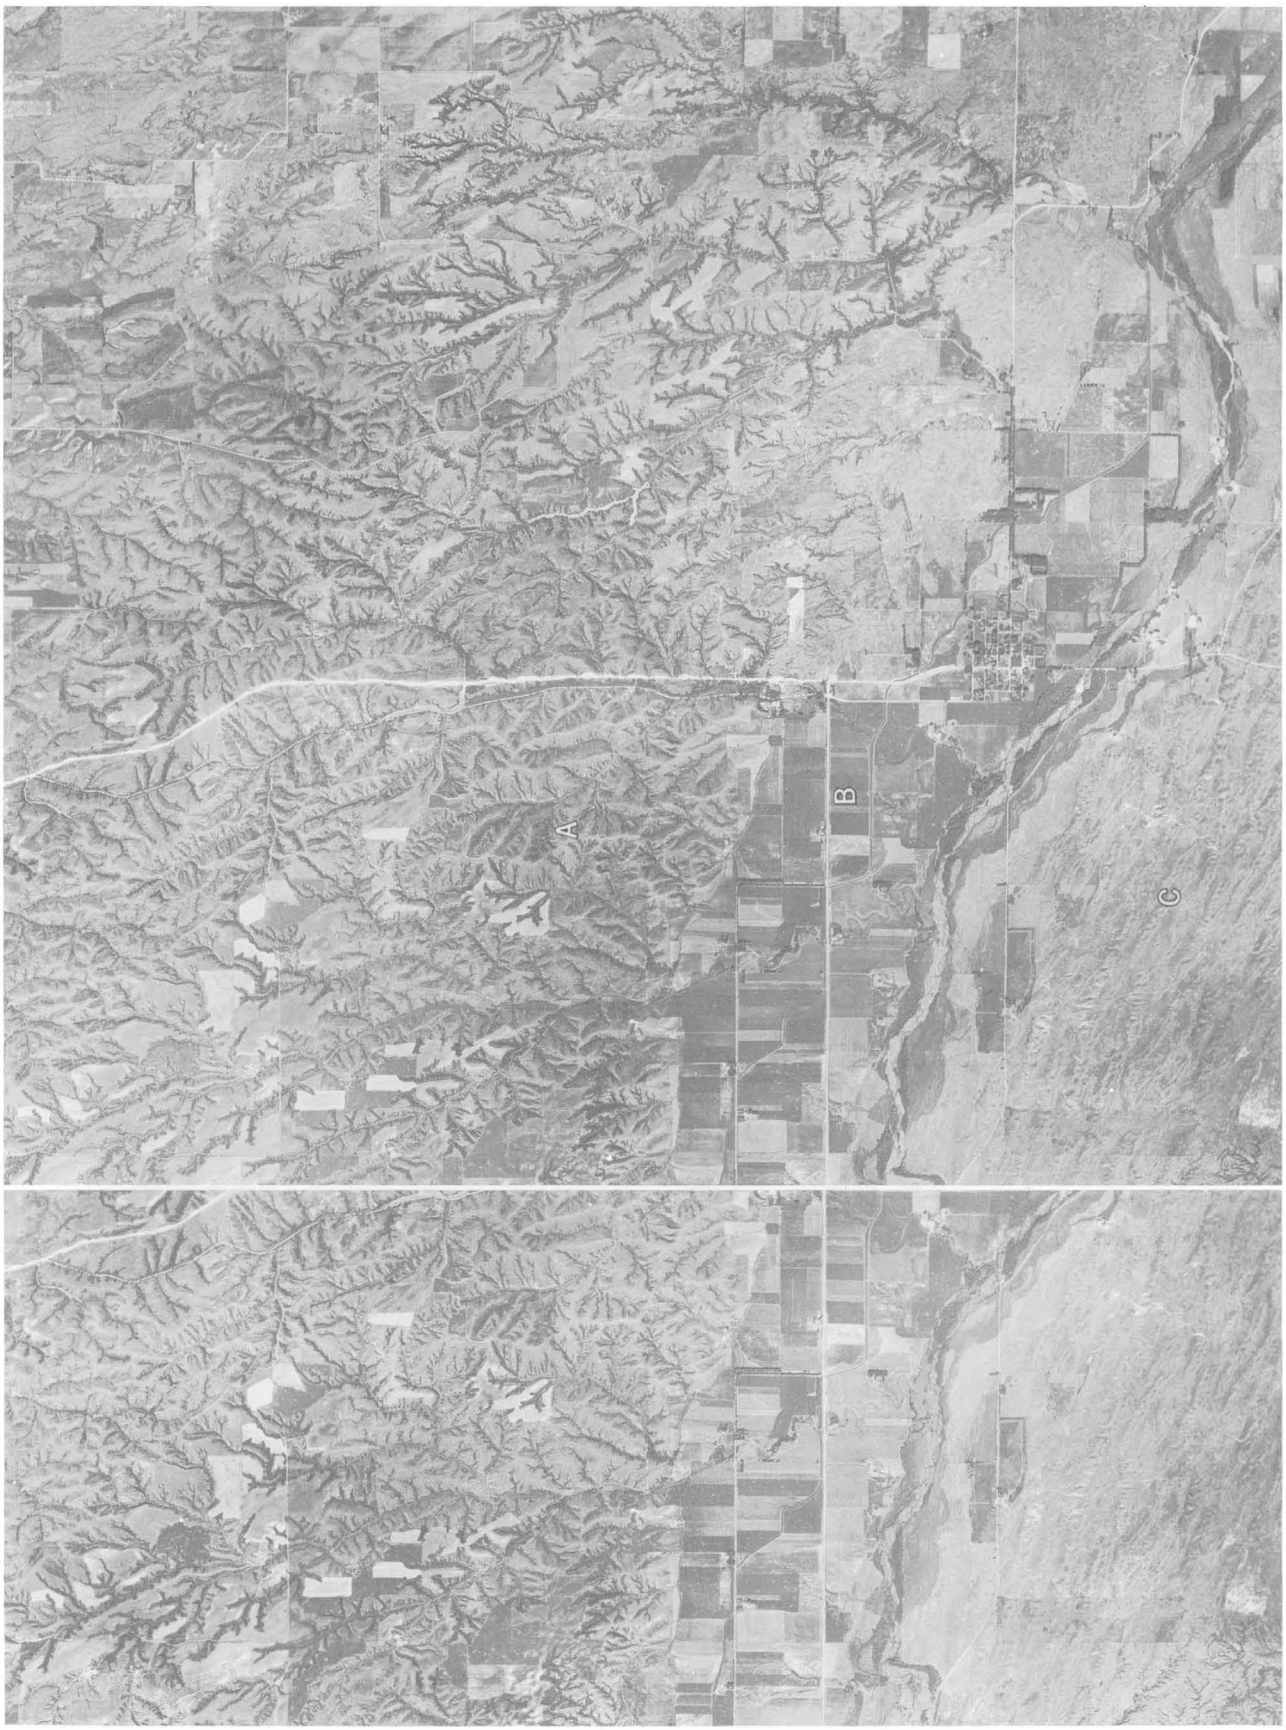
FIGURE 105.—AREAS SHOWING DRAINAGE CHARACTERISTICS IN SURFICIAL MATERIAL THAT IS PREDOMINANTLY LOESS.

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Figure *A*. Contrasting drainage characteristics and differences in photographic tones in areas *a* and *b* suggest differences in character of the surficial materials. The modified dendritic drainage and scoop-shaped valley heads are typical of dissected loess areas, *a*. Lack of surface drainage rills is a feature of sand dune areas, *b*, where materials are coarse-grained, highly permeable, and drainage is largely internal. Note light-and-dark mottled soils in sand dune area. The fine-grain size of loess is believed responsible for the fine-textured drainage (Iowa).

Figure *B*. As in area shown in figure *A*, the dissected loess hills exhibit a modified dendritic drainage pattern. Recent erosion has cut deep narrow and sharply defined channels in the bottoms of broad valleys, as at *a*. Gully walls are essentially vertical. Note characteristic scoop shape of side drainage and serrated ridges along some divides. Light streaks due to thin grass cover or to cultivation are typical of many loess areas. Broad, flat river flood plain, *b*, has good internal drainage and exhibits a lack of visible surface drainage channels (Nebraska).

Figure *C*. Deeply dissected loess hills have drainage pattern similar to areas shown in figures *A* and *B*, but erosion may have proceeded more rapidly than in other areas. Valley walls are sharply defined. Steep valley walls commonly characterize loess (Nebraska).



Stereoscopic pair

Approximately 1 mile

FIGURE 106.—AREA OF SURFICIAL DEPOSITS, PRIMARILY WINDBLOWN (CENTRAL NEBRASKA).

[Approximate scale 1 : 67,000. Photographs by Army Map Service]

Highly dissected loess hills, *A*, abut against well-drained alluvial terraces, *B*. Extensive dissection of loess has resulted in a fine texture of erosional topography and fine-textured drainage. Bottoms of many valleys in loess are notched by recent stream dissection. The modified dendritic drainage pattern is typical of loess area. Note absence of surface drainage rills in terrace alluvium, *B*, and elongate windblown sand hills, *C*, indicating the highly permeable nature of the underlying materials. Loess is generally considered well drained internally and is thus an exception to the general association of fine-textured drainage and impermeable soils. The fine-textured drainage in loess is believed to be a result of the fine grain size. Contrast appearance here of drainage density in loess with drainage density on large-scale photographs of figure 105.

Approximately 1 mile

FIGURE 107.—MOTTLED SOILS OF DRIFT PLAIN (IOWA).

[Approximate scale 1 : 27,000. Photographs by U.S. Geological Survey]

Light-toned areas are generally slightly higher than surrounding dark-toned areas. High areas of light photographic tone are somewhat better drained than the intervening dark areas, and generally contain silty soils with a lesser accumulation of organic material than the depressions. Clay materials and humus have accumulated in depressions to impart dark photographic tone. Linear pattern of light-toned areas may represent minor recessional moraines. They trend across the direction of movement of ice. Near major streams the reworked glacial drift may be better sorted and locally an important source of borrow material for the construction engineer.

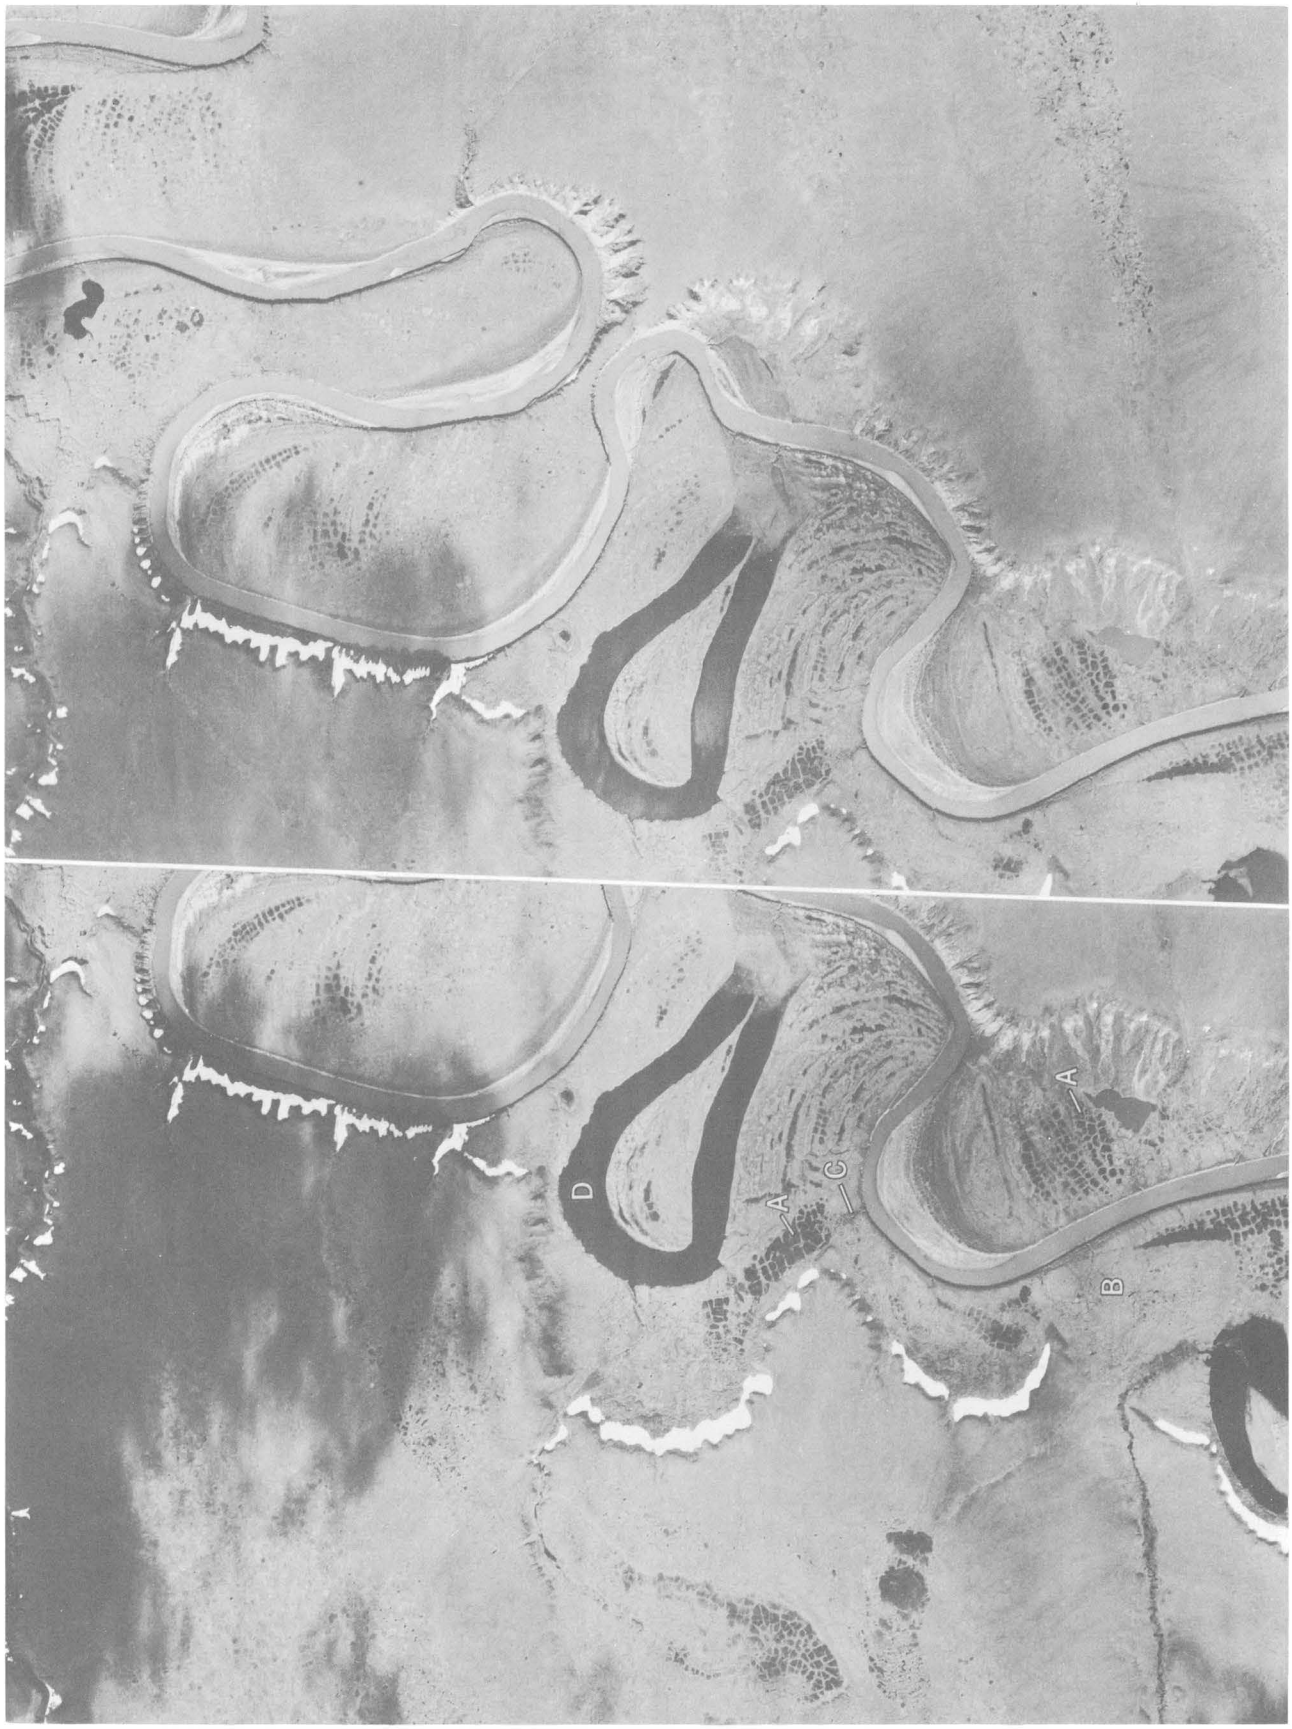
FIGURE 108.—COASTAL PLAIN UNDERLAIN BY CLAY, SAND, AND GRAVEL (NEW JERSEY).

[Approximate scale 1 : 20,000. Photographs by Commodity Stabilization Service]

Cultivated areas are thin cappings of sand and gravel overlying clay formation. Lack of surface drainage rills in sand and gravel indicate that the capping material is well drained internally. Except for dark-toned crop vegetation the cultivated areas also have the general light tones commonly associated with well-drained materials. Note borrow pit in granular material at *A*. Streams flow in clay. The steep walls and flat bottoms of gullies may not be typical of plastic clays in humid regions, however. Headward extent of small gullies generally ends abruptly against contact of clay with overlying sand and gravel. Vegetation growth is conspicuous along steep sides of gullies where trees have not been cleared for cultivation. Vegetation growth is locally favored by relatively constant supply of water that flows to surface along contact of clay with overlying sand and gravel.



Stereoscopic pair

Approximately 1 mile

FIGURE 109.—POLYGONALLY PATTERNED GROUND IN PERMAFROST AREA ALONG MAJOR STREAM (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

The susceptibility of low, poorly drained areas to the development of polygonally patterned ground resulting from ice-wedge formation is shown conspicuously along this major stream valley. Development of polygons, primarily low-center polygons, *A*, shown with relatively dark-toned centers and light-toned marginal ridges, has followed old channel scars representative of old slip-off slopes. Some high-center polygons, *B*, are also present. The angular gully pattern, *C*, is commonly found where ice wedges are melting out of polygonally patterned ground. Also note serrated edges of oxbow lake, *D*, and rim of river terraces were ice wedges in polygonally patterned ground have melted out. Contrast appearance of poorly drained river terraces here with river terraces in nonpermafrost areas where internal drainage is generally good. The conspicuous tilt of the oxbow lake and up-hill flow of stream meanders indicate that tilt is present in the aerial photographs.

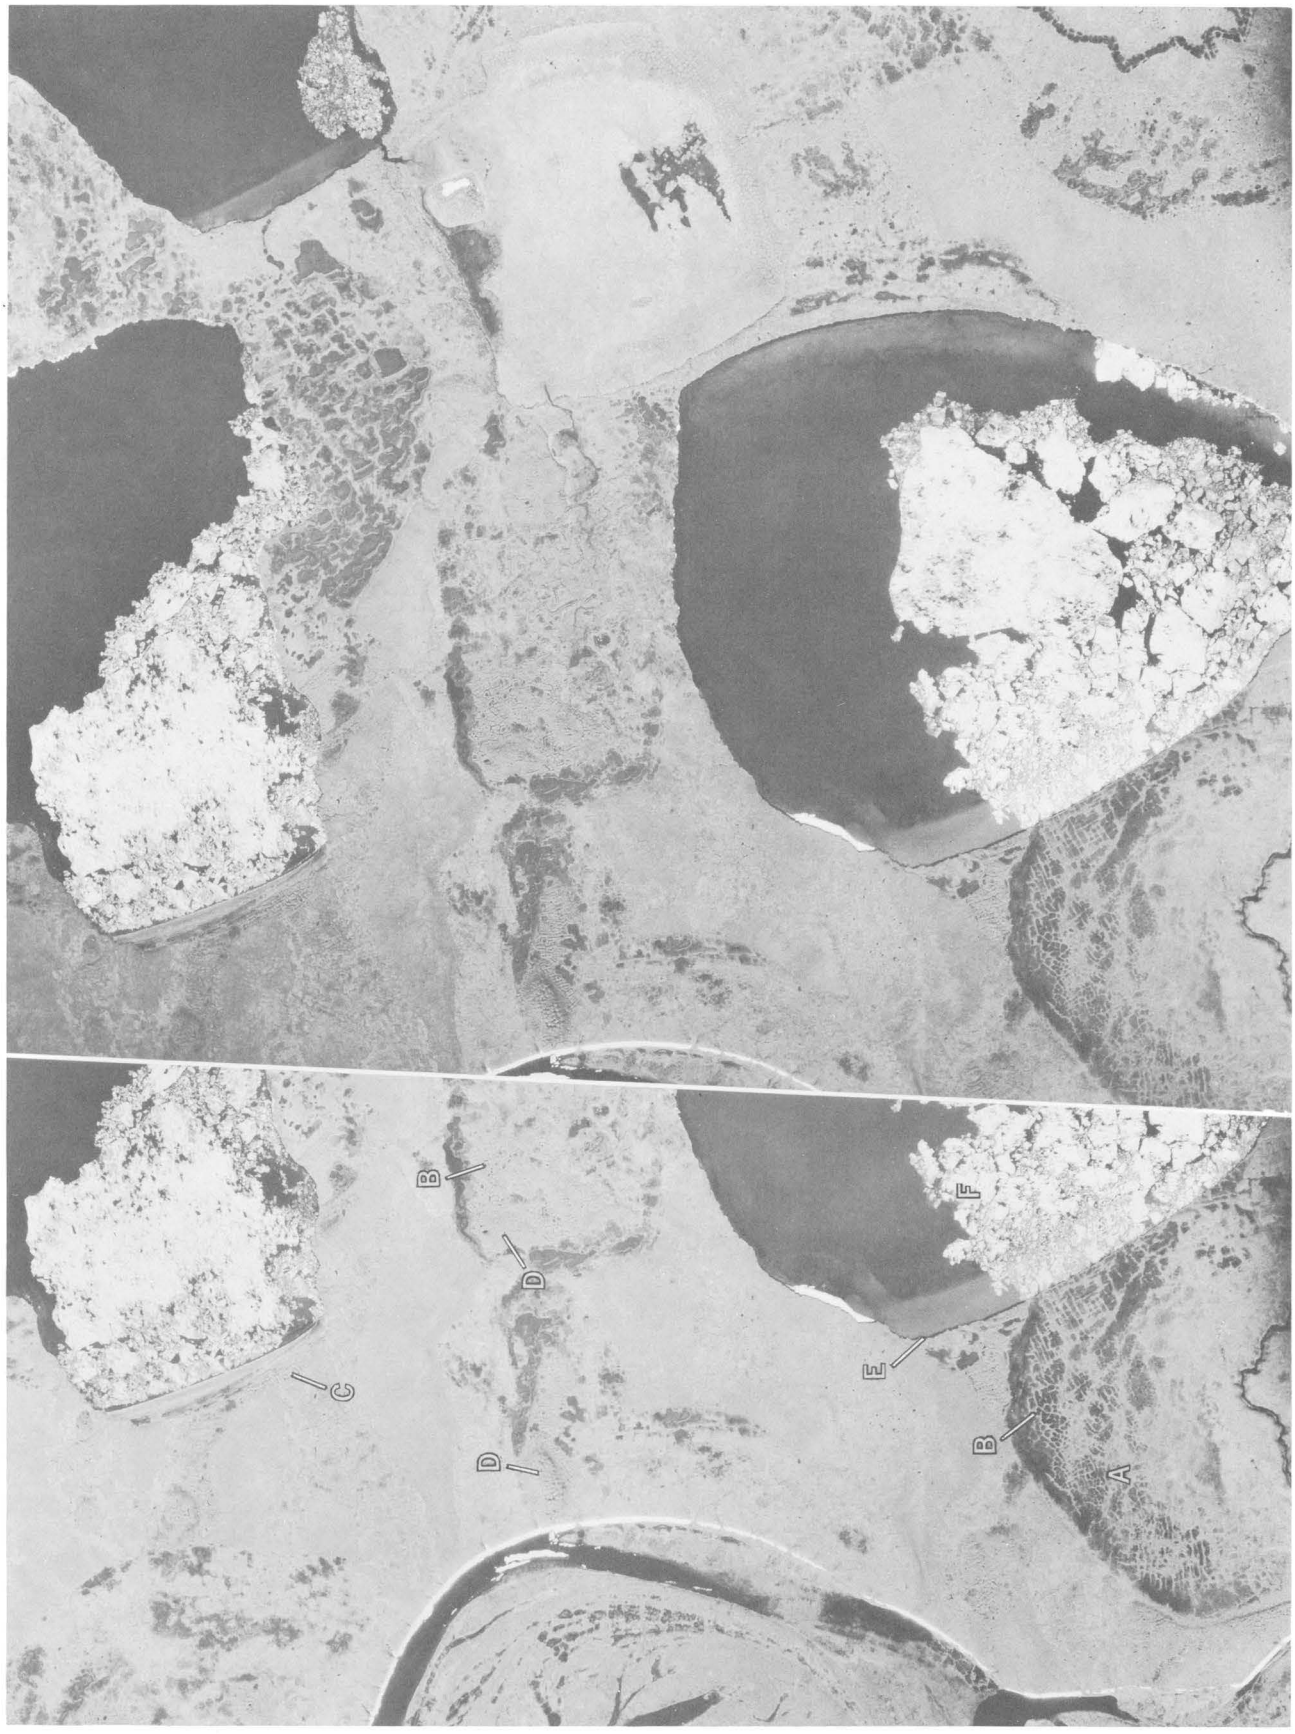
FIGURE 110.—WELL-DEVELOPED PINGO IN AREA OF PERMAFROST (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

Partly drained lake basin, *A*, a particularly favorable area for development of permafrost, is conspicuous. Note old beach lines, *B*, shown by narrow bands of contrasting photographic tones and along which polygonal ground has developed. Low-center polygons having dark-toned centers and light-toned marginal ridges are abundant, as at *C*. High-center polygons with light-toned centers and dark-toned marginal trenches, are also conspicuous in many places, as at *D*. Pingo, *E*, with a single crest crack here, is almost always diagnostic of underlying permafrost conditions. Also note pingolike forms, *F*, covered with polygonally patterned ground.



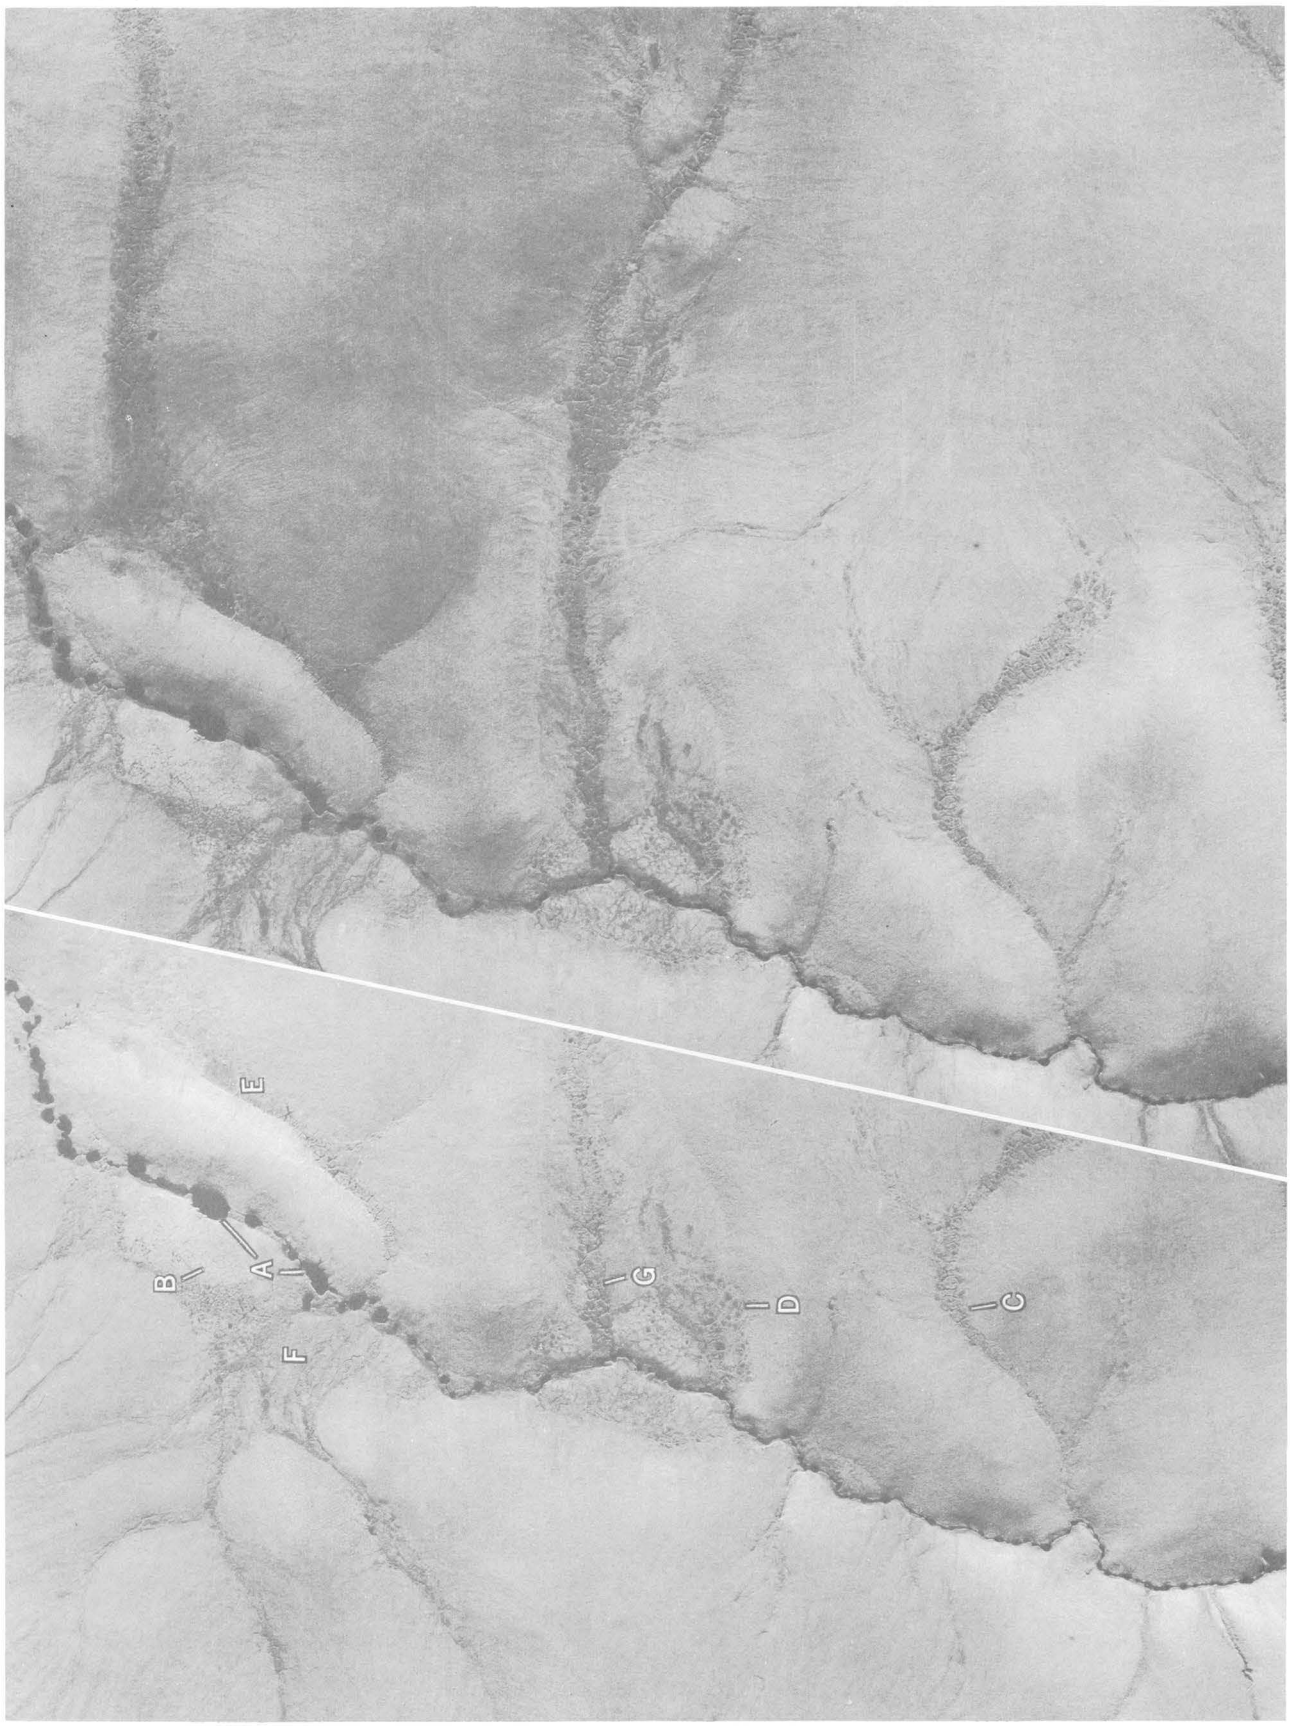
Stereoscopic pair

Approximately 1 mile

FIGURE 111.—AREA OF PERMAFROST (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

Low, wet but drained lake basins, as at *A*, are favorable areas for the development of permafrost. Low-center polygons, *B*, shown as dark-toned depressed centers and light-toned raised edges are common. High-center polygons, *C*, exhibiting high, light-toned centers, and dark-toned marginal trenches, are also present. Pingolike forms, *D*, also covered with polygonally patterned ground, are highly indicative of permanently frozen ground conditions. The serrated shoreline, *E*, of some lakes is typical of the thawing of polygonal ground and further suggests the presence of permafrost. Note floating ice, *F*; bottom of lake may be seen at edge of ice, and in places depth of water may be measured from the aerial photographs.



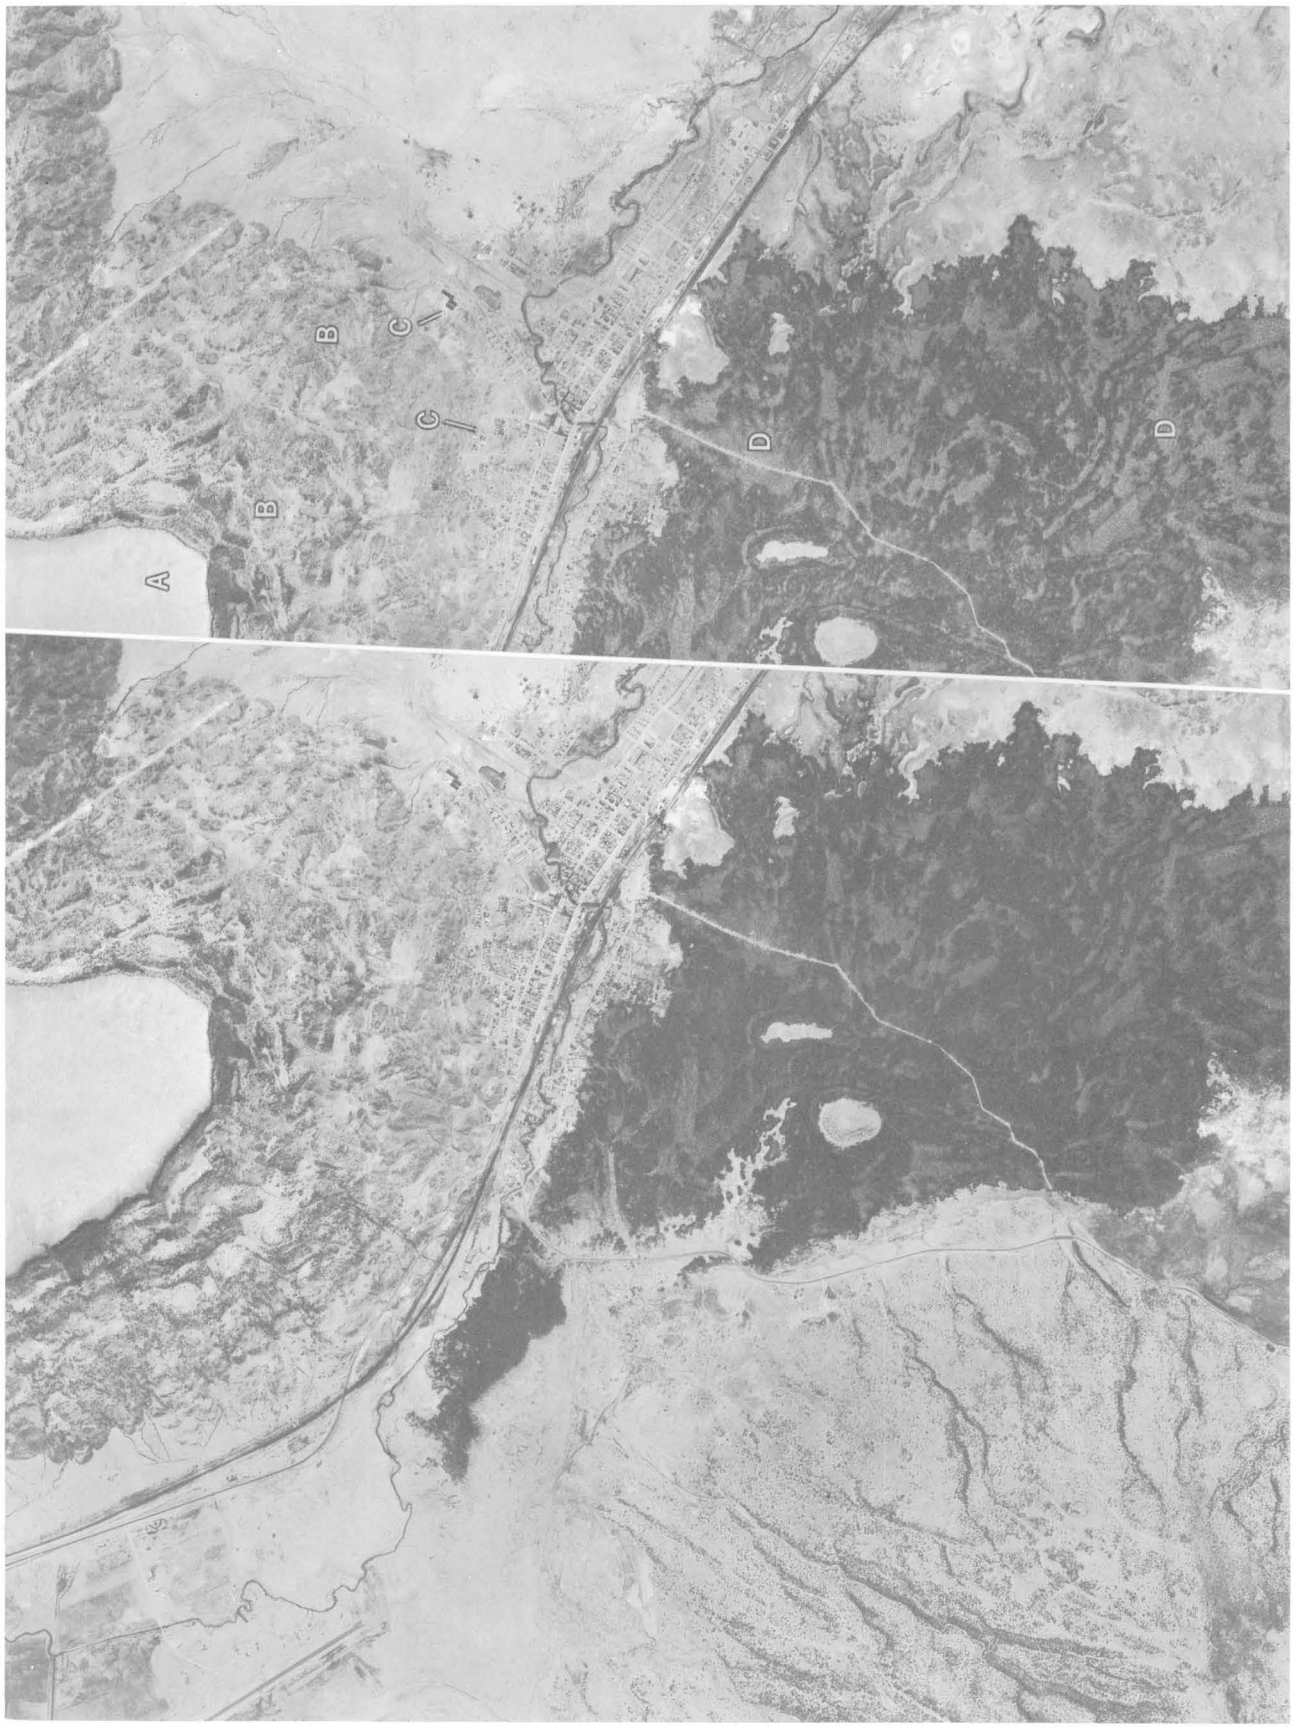
Stereoscopic pair

Approximately 1 mile

FIGURE 112.—CONSPICUOUS BEADED DRAINAGE IN AREA OF PERMAFROST (NORTHERN ALASKA).

[Approximate scale 1 : 20,000. Photographs by U.S. Navy]

Beaded drainage along main stream, shown as rounded pools of water connected by deeply incised watercourses, typically forms in areas underlain by permafrost. Note steep banks of pools, as at *A*, which have resulted from thawing of frozen ground and subsequent caving. Interpretation of permafrost conditions is supported by presence of high-center and low-center polygons. High-center polygons, *B*, generally are shown by relatively light-toned centers and dark-toned rims, although locally, as at *C*, the reverse tonal contrasts may be present. Low-center polygons with relatively dark-toned depressed centers and light-toned raised rims are shown at *D*. The wetter areas, as in the partly abandoned drainage channel, *E*, or upper reaches of minor drainageways, are especially susceptible to formation of polygons. Area *F*, probably a small alluvial fan area, shows well-developed drainage. The angular pattern may indicate incipient polygon formation in contrast to the angular pattern of drainage, *G*, which is typical of areas where melting of ice wedges in polygonal ground is taking place.



Stereoscopic pair

Approximately 1 mile

FIGURE 113.—LANDSLIDE AREA IN VOLCANIC AND SEDIMENTARY TERRAIN (NEW MEXICO).

[Approximate scale 1 : 37,000. Photographs by U.S. Geological Survey]

Resistant flat-lying basaltic lava, *A*, caps mesa underlain by weakly resistant mudstone, shale, siltstone, and sandstone, a geologic environment particularly susceptible to the occurrence of landslides. Landslides, *B*, below lava cap are characterized by hummocky topography and local lobate form suggestive of flowage. Note buildings, *C*, constructed on toe of slide areas. Recent lava flows are indicated by the dark photographic tone and irregular surfaces, *D*. The lobate character typical of flows can also be seen.

FIGURE 114.—DAMSITE AREA (SOUTHEASTERN ALASKA).

[Approximate scale 1 : 40,000. Photographs by U.S. Navy]

Conspicuous faults, indicated by linear topographic depressions *A*, *B*, *C*, and *D*, are present. The outlet of the lake itself appears to flow along a fault marked by the rectilinear depression *E*; this fault is probably the most significant geologic structure in the area because a dam would have to straddle it. Highly fractured rocks comprise metamorphic types and intrusive quartz diorite.

BASIC FIELD MANUAL

ELEMENTARY MAP AND AERIAL PHOTOGRAPH READING

Prepared under direction of the
Chief of Engineers

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON : 1941

For sale by the Superintendent of Documents, Washington, D. C.

WAR DEPARTMENT,
WASHINGTON, *April 12, 1941.*

FM 21–25, Elementary Map and Aerial Photograph Reading, is published for the information and guidance of all concerned.

[A. G. 062.11 (12–9–40).]

BY ORDER OF THE SECRETARY OF WAR:

G. C. MARSHALL,
Chief of Staff.

OFFICIAL:

E. S. ADAMS,
Major General,
The Adjutant General.

DISTRIBUTION:

B and H (3); R (10); Bn (5); C (10).

BASIC FIELD MANUAL

ELEMENTARY MAP AND AERIAL PHOTOGRAPH READING

(This manual supersedes chapter 5, Basic Field Manual, volume I, April 2, 1938.)

SECTION I

GENERAL

■ 1. PURPOSE.—The purpose of this manual is to present in simplified form necessary information for instruction of all military personnel in elementary map and aerial photograph reading.

■ 2. SCOPE.—*a.* This manual covers elementary map reading, including conventional signs and military symbols, distances and scales, directions and azimuths, coordinates, relief, slopes, profiles and visibility, map reading in the field, and aerial photograph reading to an extent sufficient to permit soldiers and platoon leaders to read aerial photographs and aerial mosaics.

b. FM 21–26 takes up the subject where this manual stops, and covers more technical phases of the subject. Other publications of a general nature pertaining to maps, mapping, and aerial photograph reading are listed in the appendix.

■ 3. NECESSITY FOR TRAINING.—Modern warfare makes it essential that personnel of all grades have the ability to read maps and aerial photographs. The detailed study of maps assists higher commanders in arriving at their tactical decisions. In transmitting orders, they often will use maps which outline their plans to their subordinate commanders. In order to carry out these orders intelligently, the subordinate commanders must be able to read any type of map involved. Maps are used to move various combat units to their assigned positions and to identify their boundaries, areas, and objectives. The supporting fires of many weapons are usually controlled by use of map data. Frequently soldiers will be given individual missions requiring them to travel long distances with only a map as a guide. Since aerial photographs or photomaps made from aerial photographs are

constantly being used as maps or to supplement maps, the necessity for training in their use is equally important as training in use of maps.

■ 4. MAPS AND AERIAL PHOTOGRAPHS.—Types of maps or aerial photographs generally issued to troops will vary a great deal depending on location of operations. Large scale topographic maps desirable for tactical operations of small units exist for only limited areas, so some of lesser accuracy normally may be expected. These may range from ordinary automobile road maps to some type of map substitute. Various types of maps and map substitutes which may be encountered are—

a. Maps compiled from existing maps.—Normally troops may expect to be furnished some type of map hastily compiled from such maps as exist at the outbreak of hostilities. These maps may vary from crude, small scale maps such as ordinary automobile road maps to accurate, large scale, topographic maps. Large scale topographic maps suitable for tactical operations of small units may be expected only in isolated areas of limited size.

b. Map substitutes.—This is a general term used to designate substitute maps that may be produced in a few hours. The map substitute may consist of direct reproduction of wide coverage aerial photographs, photomaps or mosaics, or of provisional maps. The term "photomap" is used as a general term to describe reproductions of various types of aerial photographs. A provisional map is produced by compiling existing map detail or by tracing information from aerial photographs.

c. Battle maps (fig. 1) (back of manual).—This is a map prepared normally from aerial photographs on a scale of 1:20,000, which is suitable for tactical and technical needs of all arms. Normally, this type of map would not be made available for any extensive area until at least 3 weeks after outbreak of hostilities.

■ 5. MAP CLASSIFICATION.—Military maps are generally classified according to scale as small, intermediate, medium, and large scale. (For a discussion of scales, see par. 8.) The battle map (fig. 1) referred to in paragraph 4*c*, is classed as

a large scale map. The compiled map described in paragraph 4*a* will probably be of a scale from 1:50,000 to 1:125,000, which is classed as a medium scale map. Figure 2 (back of manual) is an example of a medium scale map. Small and intermediate scale maps are used by staffs of larger units and seldom will concern commanders of small units.

SECTION II

CONVENTIONAL SIGNS AND MILITARY SYMBOLS

■ 6. CONVENTIONAL SIGNS.—*a.* Map makers have devised a common set of signs which to the map reader have a definite meaning. For instance, there are signs for a house, for a road, for a bridge, etc. These are called conventional signs. Some of them look enough like the object they are intended to represent to be easily recognized such as conventional signs for lakes or bridges. The meanings of some are not so obvious and must be learned just as new words are learned. Complete lists of conventional signs authorized for use on military maps are published in FM 21–30. Figure 3 shows some of those most commonly used.

b. Conventional signs vary in size with the scale of maps. On small scale maps comparatively few objects can be shown and the signs are reduced to their most elementary form. As the scale is increased more objects can be represented.

c. Locations of some objects are shown with more accuracy than others due to manner in which the topographer and map draftsman work. Some of these in order of accuracy are—

(1) Triangulation stations.
(2) Surveying monuments.
(3) Railroads and canals.
(4) Important bridges.
(5) Main roads.
(6) Isolated buildings on main roads, including churches and schoolhouses.
(7) Secondary roads.
(8) Streams, contours, and woodlands, cleared areas, etc.

In choosing landmarks for determining location, these relative values should be kept in mind.

d. When colors are used for War Department maps, they are used as follows: black for works of man and for grid lines; brown for contours, cuts, and fills; blue for water; green for woods and vegetation; red to indicate road conditions.

■ 7. MILITARY SYMBOLS.—Conventional signs indicate various types of terrain feaures. Military symbols have been developed to represent various types of military organizations, activities, and installations. FM 21–30 lists various standardized military symbols. Figure 4 shows some of those most frequently used. These symbols are used to indicate size and identity of various units and installations, type and location of supporting weapons, and necessary lines and boundaries for an operation. A material saving of time in giving orders for military operations may be achieved by using military symbols to outline operations on a map or a map substitute.

1. *To indicate purpose or character of activity.*

Military post or station; command post or headquarters—

(Lower end of staff or symbol will terminate at point of establishment represented.)

Troop unit—

(On large scale maps where troop units can be shown to scale, this symbol may be modified so as to show area occupied by units in column or line, thus:

Line Column .)

Observation post—

Dump, park, or distributing point (temporary depot in combat zone)—

Supply train or transportion unit—

2. *To indicate arm or service or activity of arm or service.*—These symbols will be placed generally within the symbols shown in 1 above.

SECTION III

MAP MEASUREMENTS

■ 8. SCALES.—In map reading the scale of the map is a first consideration. The scale is the relation between measurements on the map and actual distances on the ground. The scale of a map is expressed in one or more of the following ways:

a. Words and figures.—Actual equivalents given in words and figures as 3 inches equal 1 mile means that 3 inches on the map equal 1 mile on the ground; 1 inch equals 200 feet means that 1 inch on the map equals 200 feet on the ground.

b. Representative fraction.—The scale of a map may be shown as a representative fraction (usually abbreviated to RF). This fraction expresses the ratio between a given distance on a map and the corresponding distance on the ground. The RF is shown thus: 1:62,500 or $\frac{1}{62,500}$ which means one unit of distance on the map equals 62,500 such units of distance on the ground. The same kind of units of distance measured from the map must be applied to distances on the ground. For instance, in the RF shown above, 1 inch on the map equals 62,500 inches (or about 1 mile) on the ground and 1 foot on the map equals 62,500 feet (or about 12 miles) on the ground. The greater the denominator the smaller the scale; a 1:20,000 map is a large-scale map, and a 1:1,000,000 is a small-scale map.

c. Graphic scales.—The figure resembling a small ruler printed on the map is also called a scale (see fig. 5). It is divided into parts, each division being marked not with its actual length but with the distance each length represents on the ground. Usually there will be one part graduated into mile units and fractions of a mile. The other part is graduated in yards for more exact measurements of ranges, frontages, and depths. Many maps also show the kilometer scale, but this normally is used only in countries where the metric system is employed. Each graphic scale consists of a primary scale to the right of zero, and an extension to the left of zero. The extension consists of one primary unit of

the graphic scale subdivided into appropriate fractions. Typical graphical scales as used on American maps can be seen on the lower margin of figure 2 (back of manual). The scale in figure 5 has 1,000-yard units for the primary scale and ten 100-yard units for the extension.

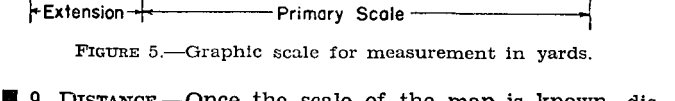

FIGURE 5.—Graphic scale for measurement in yards.

■ 9. DISTANCE.—Once the scale of the map is known, distances on the ground which are represented on the map can be determined. Even though the scale is given in words and figures or as a RF, some sort of graphic scale is usually necessary. The graphic scale is the most accurate and the most common means of determining distances from a map. Some methods of employing the graphic scale follow:

a. To find distance between two points on map (fig. 6).—(1) Lay the straight edge of a piece of paper or other material along the two points on the map. Mark the location of the two points on the straightedge by using short straight marks called "ticks" at right angles to the edge of the paper.

(2) Take the marked straightedge and place it below the graphic scale on the margin of the map to determine the ground distance required. Where the distance is greater than the length of the graphic scale, apply the primary scale one or more times until the remainder can be measured as explained above. Distances between the smallest divisions of the scale are estimated.

(3) *Example.*—(*a*) *Problem.*—Figure 6① shows a portion of a 1: 20,000 map. Required, to find actual distance on the ground between the house at A and the house at B.

(*b*) *Solution.*—Lay the straightedge of a strip of paper along A and B on the map and make tick marks. Take the strip of paper and lay its marked edge along the graphic scale on the margin of the map as shown in figure 6②. The required distance between ticks is read directly from the scale as 3,160 yards.

b. To find distance along irregular line of map.—It is sometimes necessary to measure the distance along irregular lines on a map such as a stream or a winding road. To do this, either divide the line into several approximately straight sections or, if a piece of transparent paper is available, proceed

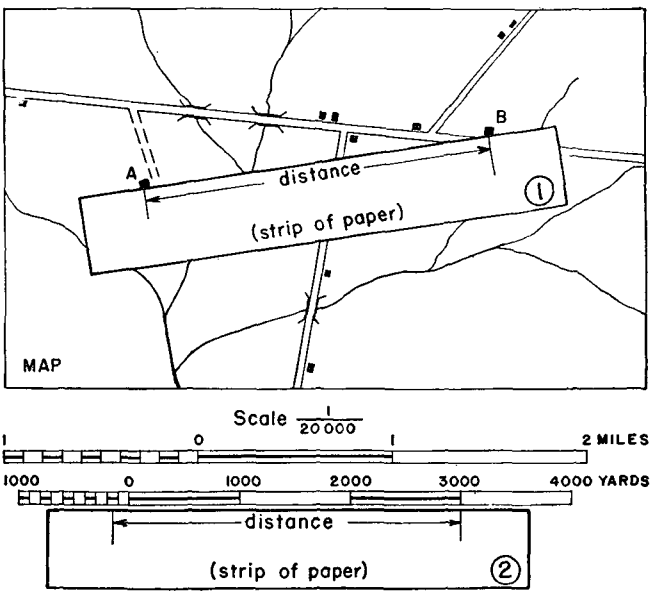

FIGURE 6.—Using graphic scale to measure distance on map.

as in (2) below. Measure the length of each section as in *a*(2) above. The sum of the lengths of the sections is the required distance.

(1) *Example.*—(*a*) *Problem.*—Required, to find distance along winding road shown in figure 7.

(*b*) *Solution.*—Take a suitable strip of paper and place it so that a tick mark along its edge coincides with A, and the edge of the paper coincides with the course A–1. Make a tick mark –1 on the paper opposite the point 1 on the map. With mark –1 on the paper held opposite 1 on the map, rotate the paper until its edge is along the line 1–2. Make

a second mark on the paper opposite 2 on the map. Continue this until B is reached; the entire distance is measured as in *a* above.

(2) *Example.*—This method also describes how to measure the distance A–B on figure 7. By means of a straightedge and a sharp pencil draw a long straight line generally down the center of any transparent piece of paper. For a starting point, draw a straight line (tick) perpendicular to and near one end of the first line. Lay the paper on the road with the starting tick over A so that the long line extends through 1. Place the pencil point at 1 and pivot the paper until the long line lies along the course 1–2. Place the pencil point at 2 and pivot the paper as before. Continue until

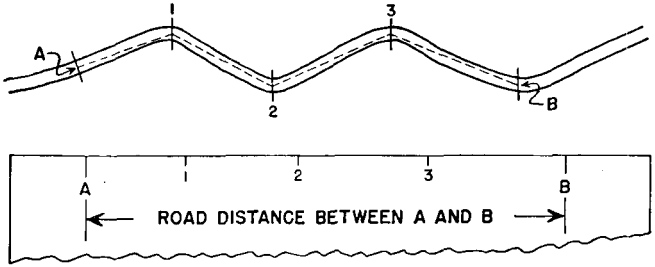

FIGURE 7.—Measuring distance along winding road.

the long line lies along course 3–B. Mark the position of B by a tick on the long line. Measure the distance along the graphic scale as described above.

■ 10. TIME.—*a. Conversion of march time to distance.*—It will often be necessary to determine the distance a column can march in a given period of time. The distance is the product of the time in hours multiplied by the hourly rate of march. For example, a motorized unit averaging 30 miles per hour can cover $4 \times 30 = 120$ miles in 4 hours. This whole distance is plotted on the edge of a strip of paper by means of the mile graphic scale. Then the distance may be laid off along the straight portions of the road by marking ticks for each change of direction along the measured portion of the strip of paper, reversing the methods shown in para-

graph 9. Thus the position of the head of the column at the end of any given time may be determined.

b. Conversion of distance to march time.—To determine how long it will take to move troops from one point to another, the distance between the two points is taken as above from any suitable map. The distance divided by the hourly rate of march gives the time required to move the troops. The habitual daytime rate of march for foot troops, making allowance for customary halts, averages 2½ miles per hour. For example, the time to march foot troops a distance found to be 15 miles on the map is 15 divided by 2.5, or 6 hours.

SECTION IV

DIRECTION AND AZIMUTH

■ **11. NEED FOR DIRECTION.**—To locate objects both direction and distance are needed. For example, an object can be located by telling in what direction and how far away it is from a given point. Most persons are familiar with the established geographic terms north, south, east, and west. These are the directions that are indicated by the common military watch compass shown in figure 8.

■ **12. UNIT OF ANGULAR MEASURE.**—*a. General.*—Angles may be measured in degrees, minutes and seconds, or in mils (see fig. 9). Normally only personnel in artillery or heavy weapons units have to use the mil since their fire-control instruments are generally graduated in mils rather than degrees. Other personnel usually use degrees, minutes, and seconds.

b. Angles.—(1) *In degrees, minutes, and seconds.*—If the circumference of a circle is divided into 360 equal parts by lines drawn from the center to the circumference, the angle at the center between any two adjacent lines is one degree. There are 60 minutes in a degree, and 60 seconds in a minute. Thus—

60″ (seconds) = 1′ (minute).
60′ (minutes) = 1° (degree).
360° (degrees) = 1 circle or a circumference.

Angles are written as 137°45′23″.

(2) *In mils.*—If the circumference of a circle is divided into 6,400 equal parts by lines from the center to the circum-

ference, the angle at the center between any two adjacent lines is 1 mil. Thus an angle would be written in mils as 1,327 mils.

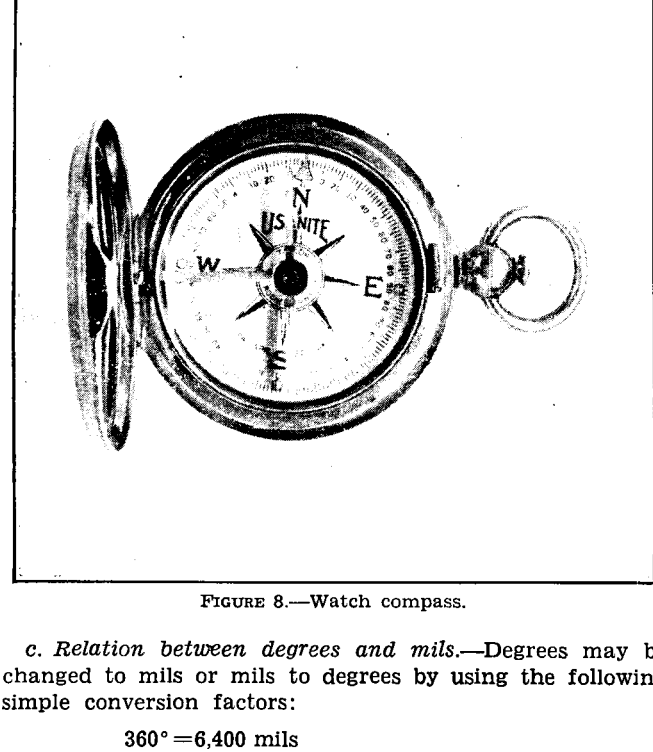

FIGURE 8.—Watch compass.

c. Relation between degrees and mils.—Degrees may be changed to mils or mils to degrees by using the following simple conversion factors:

$$360° = 6{,}400 \text{ mils}$$

$$1° = \frac{6{,}400}{360} = 17.8 \text{ mils (or 18 approximately)}$$

$$\text{Hence } 10° = 10 \times 17.8 = 178 \text{ mils (or 180 approximately)}$$

$$1 \text{ mil} = \frac{360}{6{,}400} = .056° \text{ (or 3.4′ approximately)}$$

$$\text{Hence } 100 \text{ mils} = 100 \times .056 = 5.6° \text{ or } 5°36′$$

■ 13. BASE DIRECTION.—For military purposes direction from one point to another is always expressed in terms of an angle at the initial point between the line joining the points and

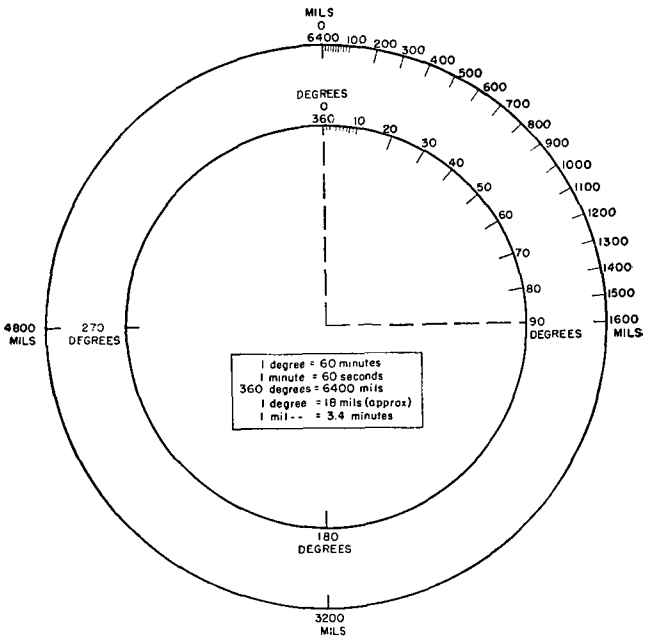

FIGURE 9.—Units of measurement.

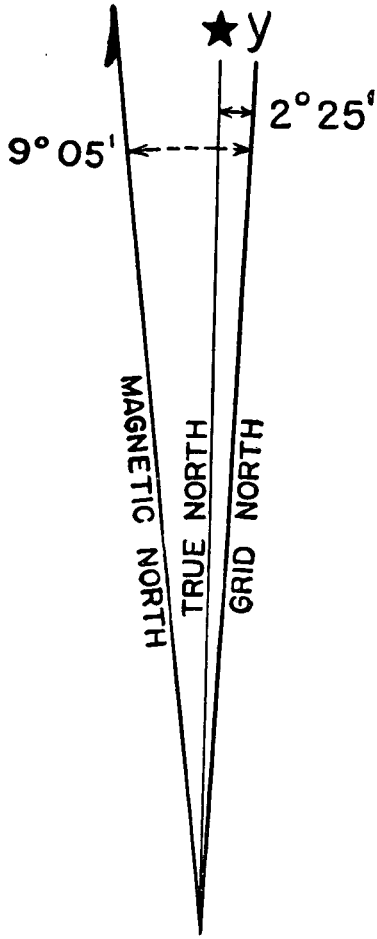
some fixed or easily established base direction line. There are three base directions from which other directions are commonly measured, namely, true north, magnetic north, and grid north, shown on maps by a star, half arrowhead, and *y*, respectively (fig. 10).

a. True north.—The direction to the true north pole. It is used in surveying or other permanent work where great accuracy is required. Where meridian or longitude lines are shown on maps they represent true north and south directions. For ordinary military map reading in the field, true



APPROXIMATE MEAN DECLINATION 1935
ANNUAL MAGNETIC CHANGE 3' INCREASE

FIGURE 10.—Declination.

north normally will be used only as base from which declinations are computed. It normally is not used as a direction in marching by compass or orienting a map. The true north line on the declination shown in figure 10 has been purposely made very light to emphasize its relative unimportance in general map reading use.

b. Magnetic north.—The direction of the north magnetic pole. It is indicated by the N (north seeking) end of all compass needles. It is ordinarily used for field work because it can be found directly by means of the common compass.

c. Grid north.—The direction of the vertical grid lines (north-south grid lines) usually found on military maps. On maps with military grid, determination of directions from grid north is convenient because grid lines are located at frequent intervals.

■ 14. DECLINATION.—Declination is the difference in direction between true north and magnetic north or between true north and grid north. There are therefore two declinations, magnetic and grid; in figure 10, magnetic declination is 9°05′—2°25′=6°40′ and grid declination is 2°25′.

a. Magnetic.—Magnetic declination is the difference between true north and magnetic north. In some localities the compass needle points east of true north; in these localities its magnetic declination is east. In some localities the compass needle points west of true north and in these localities the magnetic declination is west. In some instances, true north and magnetic north are the same, in which case the magnetic declination is zero. The magnetic declination may vary annually by small amounts. On military maps there is usually shown in the margin a diagram of the declination with the annual change, if any. For example, in figure 10 the magnetic declination is 6°40′ west as of 1935, and the annual change is 3′ increase. In 1940 (5 years later) the magnetic declination is 6°40′ plus 5×3′ or 6°55′.

b. Grid.—Grid declination is the fixed difference in direction between true north and grid north. This declination is always the same on any given map. Grid declination reaches a maximum of 3° either east or west of true north depending on the locality. On military maps it is shown on the same

diagram as the magnetic declination. Thus in figure 10 the grid declination is 2°25′ east and there is no annual variation.

c. Use.—Figure 11 illustrates three positions of grid, magnetic, and true north. There are other possible positions. In ordinary map reading the difference in direction between grid north and magnetic north is desired rather than their difference from true north. This can be found in the three examples as follows: in figure 11① the difference between mag-

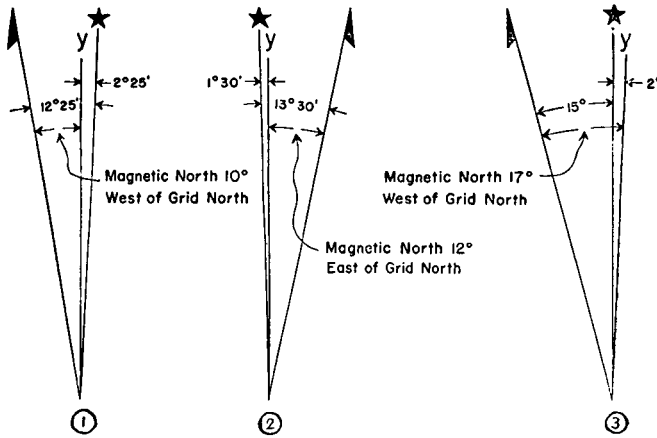


FIGURE 11.—Determining difference in direction between grid and magnetic north.

netic and grid declination is seen by inspection to be 10°0′ (12°25′—2°25′). In ② it is 12°0′ (13°30′—1°30′). In ③ it is 17°0′ (15°0′+2°0′). In the other possible positions of these lines, the declination is determined in a similar manner. When starting to use a map, determine the angle between magnetic north and grid north as described above. Write this down on the map and figure all azimuths on this basis.

■ 15. AZIMUTH.—In describing the position of one point on a map or in the field with reference to some other point, we use a standard system of measuring direction. In military work the azimuth method has been adopted for the purpose. Military azimuths are generally measured clockwise from mag-

netic, true, or grid north. Thus there are three kinds of azimuth for any given line: magnetic, true, and grid.

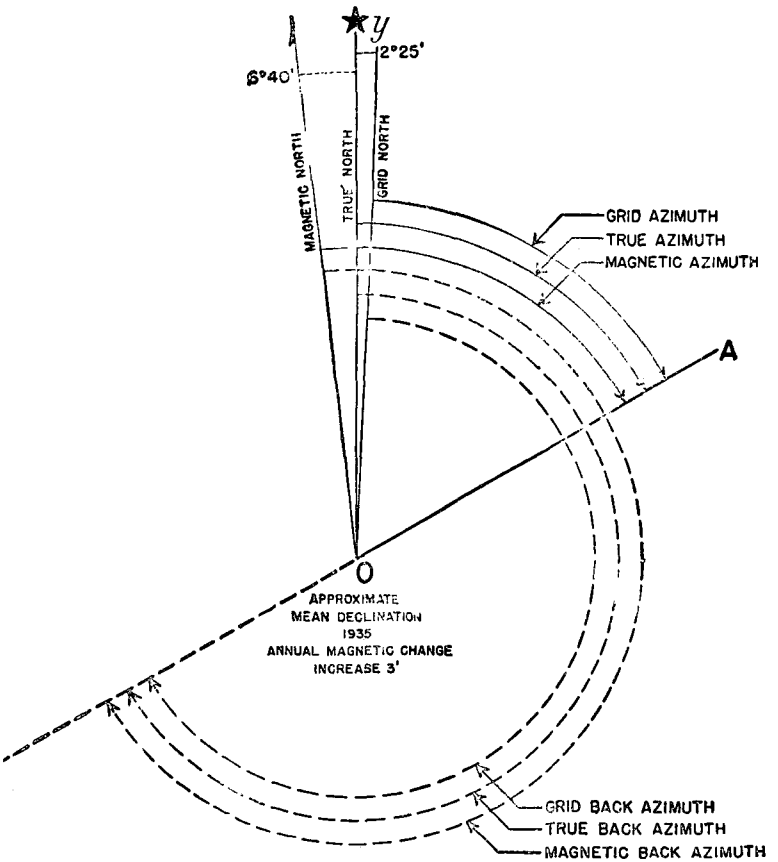

FIGURE 12.—Example of relationship between three base directions on a map, showing corresponding azimuths and back azimuths of line *OA*.

a. Magnetic.—The magnetic azimuth of any given line is the angle measured clockwise from magnetic north to the given line (fig. 12).

b. True.—The true azimuth of any given line is the angle measured clockwise from true north to the given line (fig. 12).

c. Grid.—The grid azimuth of any given line is the angle measured clockwise from grid north to the given line (fig. 12).

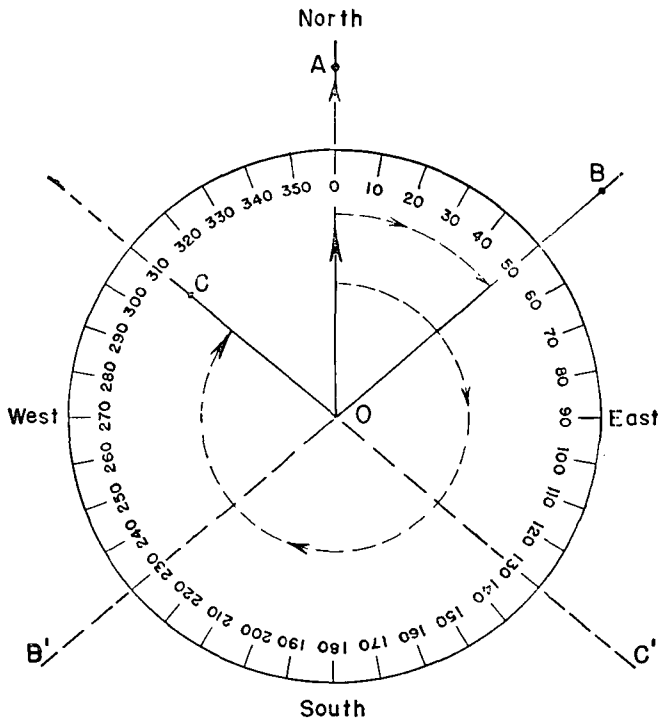

FIGURE 13.—Azimuth circle.

d. Back.—Depending on the direction in which a line extends, its azimuth may be expressed in two ways, either as forward azimuth or as back azimuth. The back azimuth of a line is its forward azimuth plus 180°. (If the sum is greater than 360°, subtract 180° from the forward azimuth to secure the back azimuth.) For example, in figure 13 the azimuth of the line extending in the direction O to B would be 50°.

The azimuth of the same line extending in the direction B to O is 50° plus 180° or 230°, which is the same as the azimuth of OB'. Similarly the forward azimuth of the line extending from O to C is 310°. Since the sum of the forward azimuth plus 180° is greater than 360°, the back azimuth or the azimuth of the line extending from C to O is 130° (310°—180°), which is the same as the azimuth of OC'. Back azimuths may be magnetic, grid, or true the same as forward azimuths and the proper designation should be included in the expression as, "Azimuth OC' 130° (magnetic)."

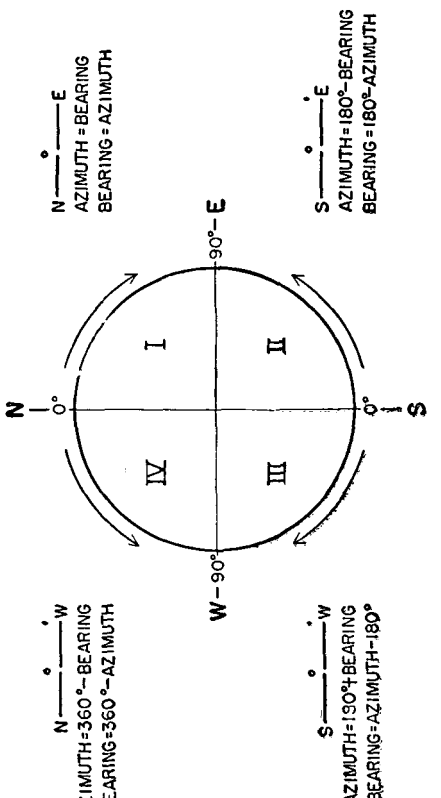

FIGURE 14.—Diagram indicating relation between bearing and azimuth.

■ 16. BEARING.—The new lensatic compass gives direction by magnetic azimuths. Watch compasses, many of which are still in use, give directions by bearings. A bearing of a

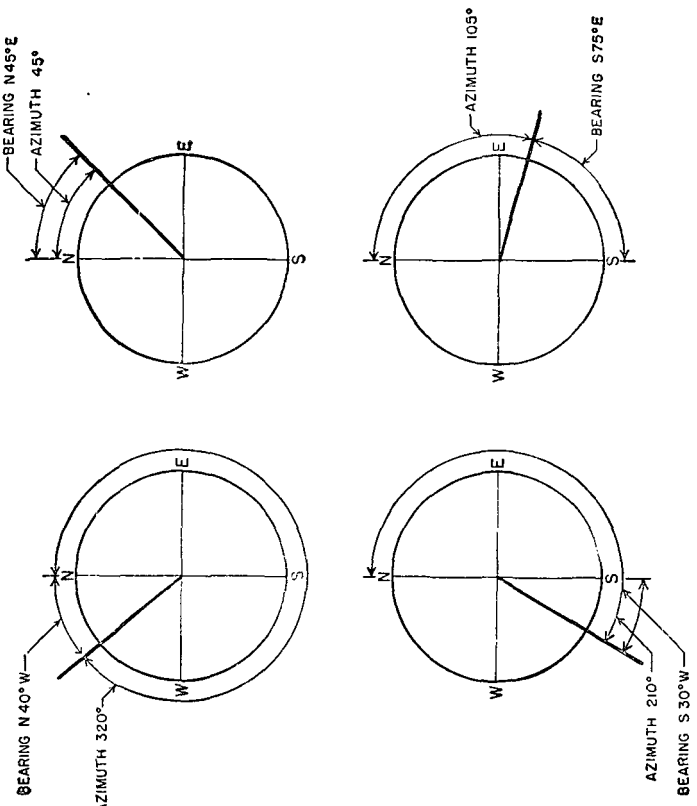

FIGURE 15.—Typical direction expressed as azimuth and as bearing.

given line is an angle and direction which the line makes with respect to a north or south direction line. Bearings are stated by quadrants (quarters of circles) and never exceed 90°. Figure 14 shows how bearings are measured and

indicates relationship between bearings and azimuths. Figure 15 illustrates the expression of a typical direction in each quadrant both as an azimuth and a bearing.

■ 17. PROTRACTOR.—Angles of azimuth or bearing are measured or laid off on a map by means of an instrument called a

■ 18. To Measure Azimuth of Any Line on Map (fig. 17).—*a.* Required, to find the grid azimuth of the line from the CR (crossroads) at A to the house at B. Extend the line AB until it intersects the 349 grid line. Lay a protractor on the map with its center at this intersection and the straight portion lying along the 349 grid line. Read the grid azimuth of AB. This azimuth is seen to be 137°.

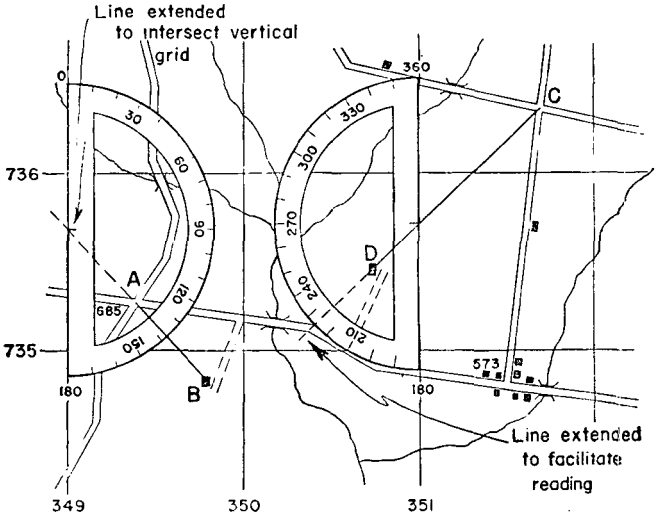

Figure 17.—Using protractor to measure map azimuth. Azimuth of line *AB* is 137°; of *CD* is 226°.

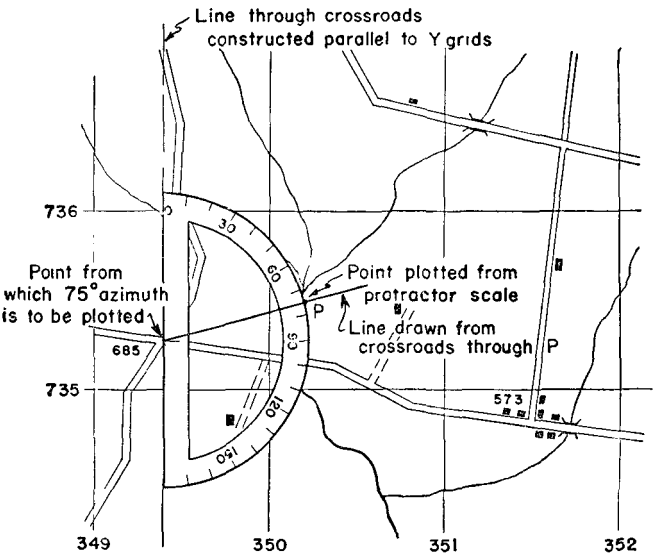
b. Required, to find the grid azimuth of the line from the CR at C to house at D. Extend the line CD a sufficient distance so that it will extend beyond the edge of the protractor. Lay the protractor on the map with its center at the intersection of CD with the 351 grid line and the straight portion lying along the 351 grid line. Since the azimuth of the line is greater than 180°, the scale reading from 180° to 360° will be used to determine the azimuth of CD. This azimuth is 226°.

■ 19. To Plot on Map Line With Given Azimuth (fig. 18).—Required, to plot from CR (crossroads) 685 a line with a grid azimuth of 75°. Construct a line through the CR parallel to the north-south grid. Lay a protractor on the map with its base on the line and its center at the CR. Plot the point P at the 75° reading on the outer scale of the protractor. Remove the protractor and draw a line from the CR through P.

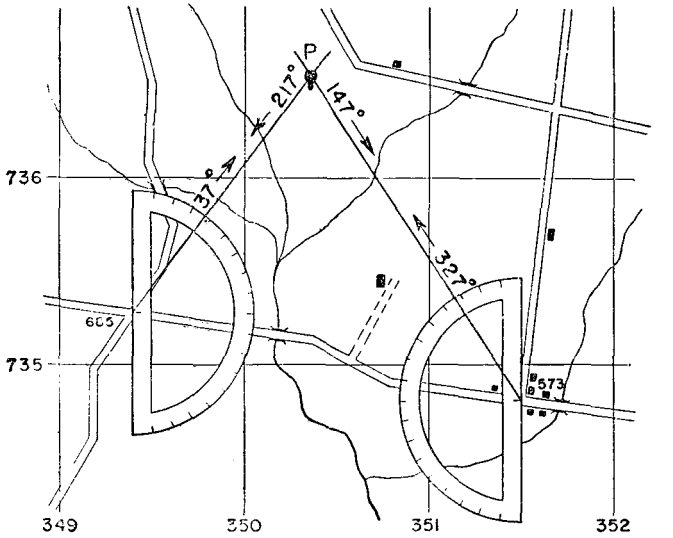


Azimuth of 75° plotted from crossroads 685.

Figure 18.—Plotting azimuths.

■ 20. Locating Point by Intersection and Resection.—*a. General.*—Sometimes it will be necessary for patrol leaders or other military personnel to determine map position of points or objects located either in enemy or other inaccessible territory. Also it may be necessary to find their own map position from inaccessible but visible points that are shown on the map. Figure 19 shows how both these operations can be accomplished.

b. Intersection.—Required, to find map position of an enemy gun that has been spotted at the point P (fig. 19) on the ground. Both CR 685 and RJ 573 are in our territory and the enemy gun is visible from both of these points. By means of a prismatic compass, the magnetic azimuth was taken from CR 685 to the gun at P. Reduced to grid azi-



Where azimuths from road junctions to gun are known, their plotting gives location of the gun. Where azimuths from gun to road junctions are known, they can be converted to back azimuth and gun position plotted as before.

FIGURE 19.—Locating points by intersection and resection.

muth, it was 37°. This grid azimuth was then plotted from CR 685 as shown. Likewise, the magnetic azimuth from RJ 573 to P was taken and reduced to grid azimuth. The grid azimuth was 327°. This azimuth was then plotted from RJ 573. The intersection of these plotted azimuths gives the map position of the gun at P which can be checked by additional similar observations. Observation points should be selected such that the plotted azimuths cross at as near

a 90° angle as possible so that the point of intersection is definite.

c. Resection (fig. 19).—(1) Required, someone at P to find map position of gun at P. This gun is in our territory but no landmarks or other easily identified terrain features are close enough to permit location from these points. However, CR 685 and RJ 573 are visible from P and are also shown on the map. The azimuths from P are read to both road intersections. These azimuths are then converted to grid back azimuths and plotted as before, giving the map position of the gun.

(2) Note that in using these two systems no measurement of distance is required. Location of position is determined merely by reading two angles and plotting two lines.

SECTION V

LOCATION BY COORDINATES

■ 21. GENERAL.—In military operations it is frequently necessary to refer to points on the ground or terrain features in short, convenient, unmistakable terms. The easiest way to accomplish this is to designate the point when given on a map by its name or number. Military maps often show names or numbers of all important locally known features. Hills, road junctions, and crossroads are often given numbers, usually in terms of their elevation in feet above sea level, thus serving the dual purpose of designating the feature and also giving its elevation. But it is not possible to number or name all features of military value on a map. Also it is often difficult to find such points on the map even when they are named or numbered. Thus some simple method or system for describing the position of a point or a place on a map is essential for quick and accurate identification. The use of coordinates has been adopted to serve this purpose. There are several types of coordinate systems but the polar and the military grid are the two types most used and ones with which all officers and enlisted men must be familiar.

■ 22. POLAR COORDINATES.—This system consists of locating a feature by giving its distance and direction from a nearby

landmark, the name and location of which is known or shown on the map. Polar coordinates are commonly used in designating points located with a compass in the field and in designating positions on maps not equipped with the military

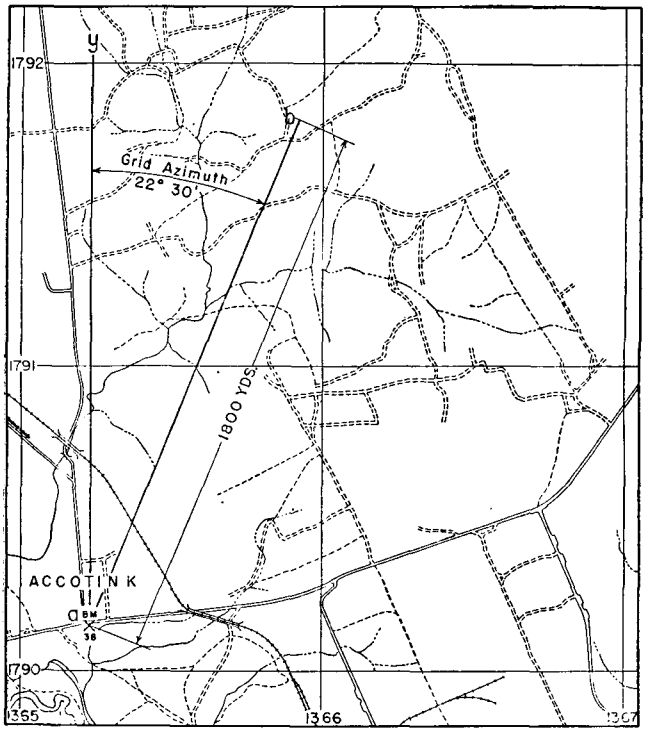


FIGURE 20.—Polar coordinates of b from BM 38, Accotink (village), distance 1,800 yards, on grid azimuth 22°30'.

grid. They are also frequently used in connection with ordinary field sketches. The landmark and selected direction must be clearly described in addition to stating the distance and angle. Polar coordinates are commonly used by reconnaissance patrols sent out to locate enemy installations. The

information brought or sent back by such patrols is usually in the form of a sketch. This sketch gives the distance and a magnetic azimuth to the enemy locations from point of observation of the patrol. Distance is estimated and azimuth read with the compass carried by the patrol leader. From these sketches it is possible to plot the position of these enemy installations on a map. Magnetic azimuths are changed to grid azimuths as stated in paragraph 15, and distance plotted along this azimuth line from the stated point of observation of the patrol. For example (see fig. 20), a patrol sends back information that an enemy position is located at b, an estimated distance of 1,800 yards on a magnetic azimuth of 31°30′ from BM 38 located in Accotink village. On this map, the magnetic north being greater by 9° than grid north, company headquarters, on receiving this information, changes the magnetic azimuth of 31°30′ to a grid azimuth of 22°30′. It then can plot the enemy position (point b) at a distance of 1,800 yards to scale from BM 38 in Accotink village along this grid azimuth as indicated in figure 20.

■ 23. MILITARY GRID.—*a. General.*—To make the reading of military maps easy, grids are printed on the map. The grid is simply a set of numbered north and south lines showing distance in thousands of yards east of the origin, and a set of numbered east and west lines showing distances in thousands of yards north of the same reference point. On a large-scale map (for example, 1:20,000 (par. 5)) these lines are 1,000 yards apart. On the medium-scale map (par. 5) the lines are 5,000 yards apart.

b. Location by grid coordinates.—Points are designated by coordinates simply by the intersection of the north-south grid lines (vertical lines) with the east-west grid lines (horizontal lines). Thus, in figure 21, location of the point A is indicated by the intersection of the 198 grid line and 262 grid line; the coordinates of the point therefore are (198–262). Note that distance east of origin is called the X-coordinate and is read first; and that distance north of origin is called the Y-coordinate and is read last. Beginners often make the error of reading the wrong coordinate first. One way to avoid this is to remember the key phrase "READ-

RIGHT-UP." It often may be necessary to designate points which do not fall at the intersection of grid lines. For example, it is required to find the coordinates of point B in figure 21. If it is assumed that the sides of the grid square are further subdivided into 10 equal parts, it is seen that the point B is 8 of these parts east and 7 of the parts north of the southwest corner of the square in which B is located. The coordinates of the point B are therefore written (197.8–263.7). Often sufficiently close determination can be made by estima-

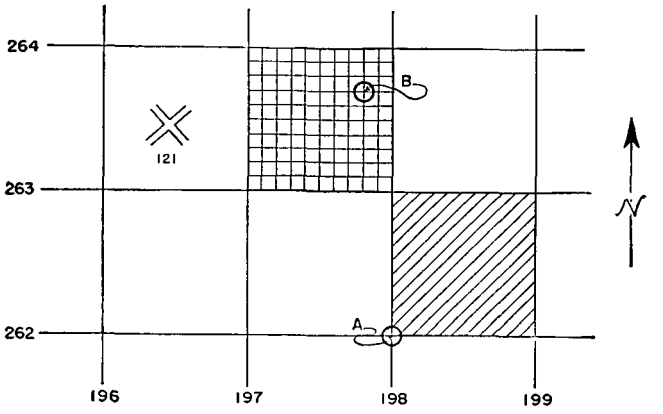

FIGURE 21.—Coordinates.

tion. For example, CR (crossroads) 121 could be located by inspection at (196.4–263.4). Since on all commonly used large-scale maps the grid square measures 1,000 yards on a side, a reading to tenths (one decimal place) gives a location to the nearest 100 yards. A reading of hundredths (two decimal places) gives an accuracy within 10 yards. When the grid numbers have more than two digits, it is customary to drop off all but the last two digits. Thus, the coordinates of point B above may be written (97.8–63.7), or if greater accuracy is desired (97.80–63.70).

c. Location by grid squares.—When a point is easily identified such as a numbered cross road or a town, it is necessary merely to refer to the southwest corner of the grid square in

which it is located. For example, in figure 21 crossroads 121 could be designated as CR 121 (96–63).

■ 24. COORDINATE SCALE.—*a. General.*—In paragraph 23*b*, the coordinates of point B were found by subdividing each side of the square (197–263) into 10 parts. This operation is used

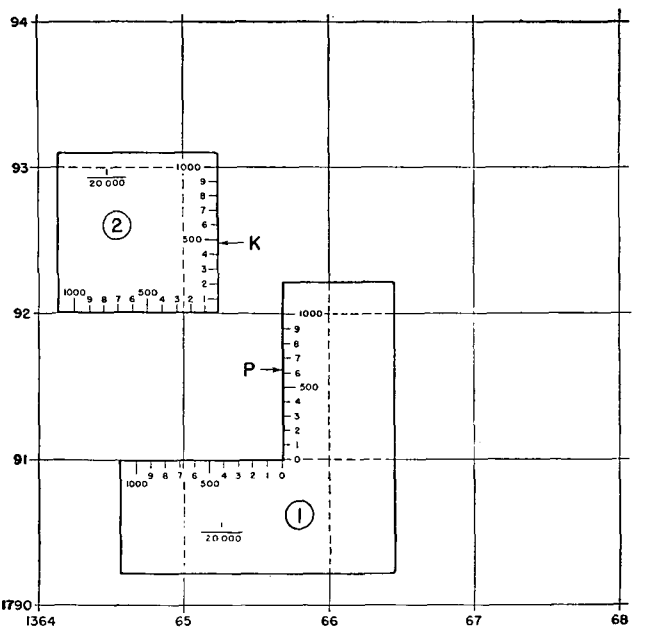

FIGURE 22.—Plotting point with coordinate scale.

only for explanation and is too long and tedious for normal use. A grid coordinate scale or card as shown in ① and ②, figure 22, permits finding these coordinates rapidly and easily. These cards may be made of cardboard, metal, or celluloid. For large-scale maps having grids 1,000 yards apart, lay off on the interior edges 1,000 yards to the scale of the map. Beginning at the vertex divide each 1,000 yards into 10 equal parts. This may be done by means of the graphical scale

printed on the map. For medium-scale maps having grids 5,000 yards apart, lay off on the inner edges 5,000 yards to the scale of the map, and subdivide each 1,000 yard division into

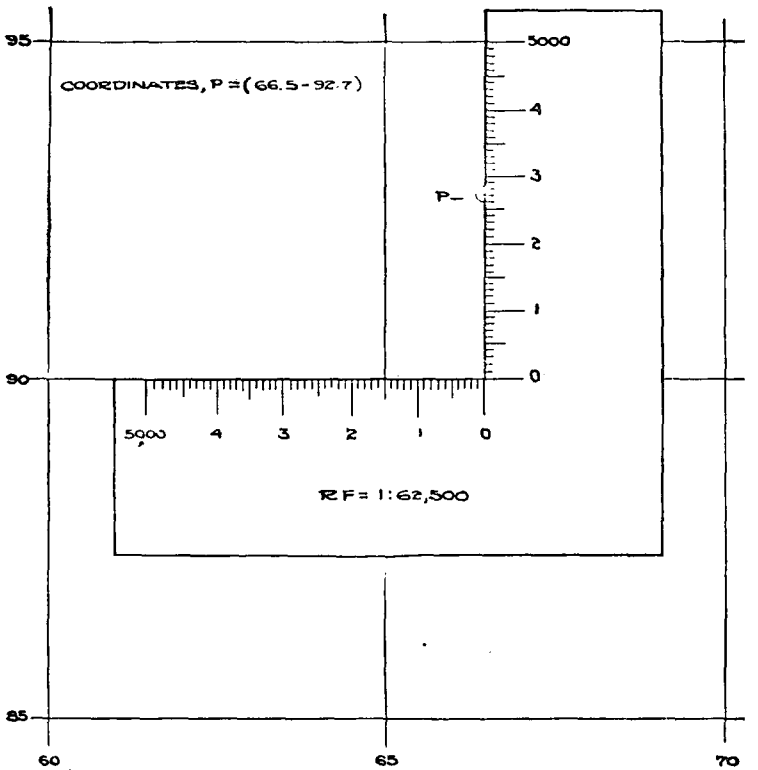

FIGURE 23.—To read grid coordinates of point on map (1:62,500) with 5,000-yard grid by means of coordinate scale. (Not reproduced to scale.)

10 equal parts as described above (fig. 23). The L-shaped type is more convenient to use. However, the rectangular type (① and ②, fig. 22) may be readily improvised by use of any square piece of cardboard or heavy paper.

b. To read coordinates of any point on map using coordinate scale.—Required, to find coordinates of point P (fig. 22). First identify the square in which P lies and write the coordinates of the lower left (southwest) corner of the square thus (1,365–1,791) or, dropping off the first two digits as described in paragraph 23*b*, it could be written (65–91). Now place the coordinate scale with its horizontal (east–west) edge on the 1,791 grid line. Keeping this edge on the 1,791 grid line, slide the scale along until its north-south scale passes through the point P. The decimal portion of the X-coordinate is read on the horizontal (east–west) scale, where it is cut by the west boundary of the square (in this case the 1,365 grid line). The decimal portion of the Y-coordinate is read on the vertical (north-south) scale, at the point P. These readings are then filled in at the proper places after the coordinates already written down. Reading to the nearest 100 yards, the coordinates of P are (1,365.7–1,791.6) or (65.7–91.6). Reading to the nearest 10 yards the coordinates are (65.68–91.62). The coordinates of K are (65.25–92.48). Similarly for the medium scale map shown in figure 23 the coordinates of the point P are (66.5–92.7).

c. To plot on a map any point whose coordinates are given.—This process is the reverse of determining the coordinates of a point. For example, in figure 22 let us assume that it is required to plot the position of the point P whose coordinates are (1,365.68–1,791.62). Place the coordinate scale on the map as shown in position ① in figure 22. The position of P can be marked at once with a pin or sharp pencil.

SECTION VI

ELEVATION AND RELIEF

25. GENERAL.—*a. Ground form and elevation.*—Up to this point the map has been regarded as a representation of a flat surface and only the horizontal position of features indicated thereon has been considered. A map to be of the greatest practical value must convey to the user a definite impression of ground forms (hills, ridges, and valleys) known as relief. This brings up the important subject of elevations.

By elevation is meant the vertical distance of any specified point on the earth's surface above a selected reference plane, which for most maps is mean sea level.

b. Means of representing relief and elevation.—Since a map is a plane surface, some type of conventional sign must be used in order to represent relief and elevation. On most modern topographical maps, this is accomplished by the use of contours. Other methods such as hachures (par. 28) and

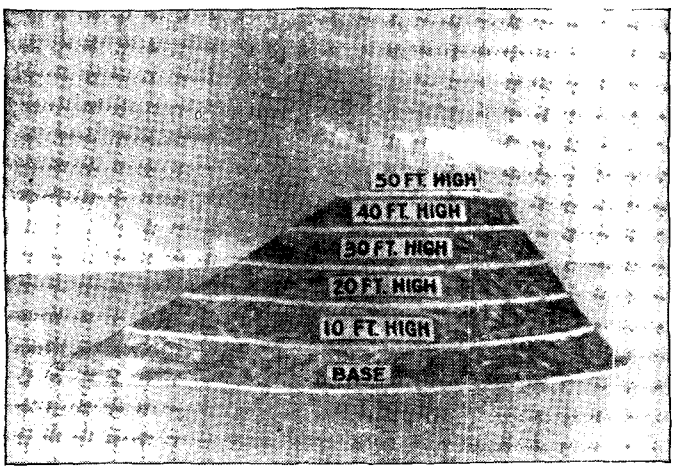

FIGURE 24.—Side view of hill.

hill and valley shading are used but contouring is the most common and practical method.

26. CONTOURS.—*a. General.*—Contours are the conventional signs drawn on a map to show the different ground forms. After practice with contours the map reader cannot only visualize shapes of hills, mountains, and valleys, but can also find elevation of points and determine slope and visibility along given lines. A contour is a line drawn on a map which represents an imaginary line on the ground all points of which are at the same elevation. Figure 24 represents a hill in the middle of the ocean. The seashore line itself would be the base or zero contour. If the sea should rise 10 feet

the new seashore line would mark the 10-foot contour. Similarly the next higher contour line would be marked for each rise in elevation of 10 feet. Figure 24 shows the successive increases in sea level which indicate contours. Figure 25 gives an oblique view of this same hill. From directly above, the hill would appear as in figure 26. Figures 24, 25, and 26 are photographs. Consequently, wiping out the picture of the hill itself, it would appear on a map as in figure 27 when indicated by contours alone.

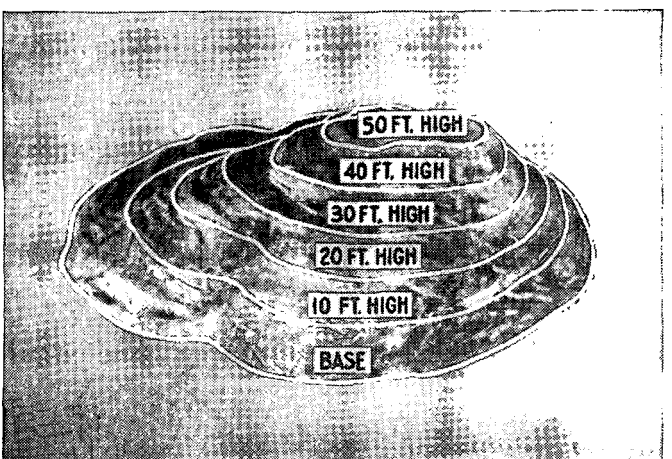

FIGURE 25.—Oblique view of hill.

b. Characteristics.—Figure 28 represents a number of more common ground forms as they are shown by contours. Looking at this figure it should be noted that—

(1) Contours have a characteristic wavy appearance.

(2) Elevation of contours above the reference plane (mean sea level) is shown by numbers usually in feet.

(3) At A, B, and C are contours which are closed curves, indicating either hilltops or depressions. Since the contour numbers increase as these points are approached it is apparent that A, B, and C are actually on hilltops.

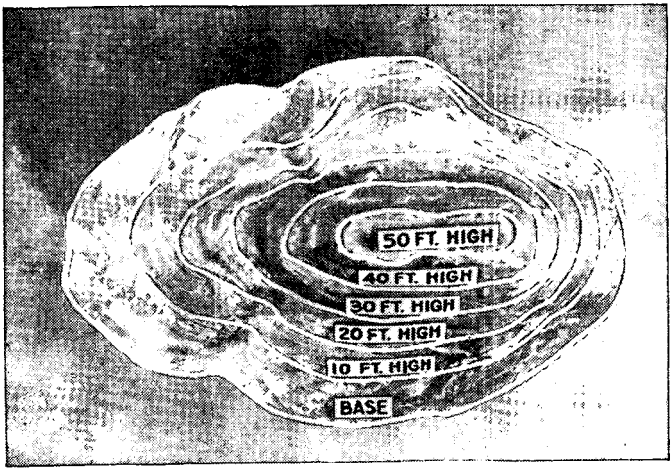

FIGURE 26.—Top view of hill.

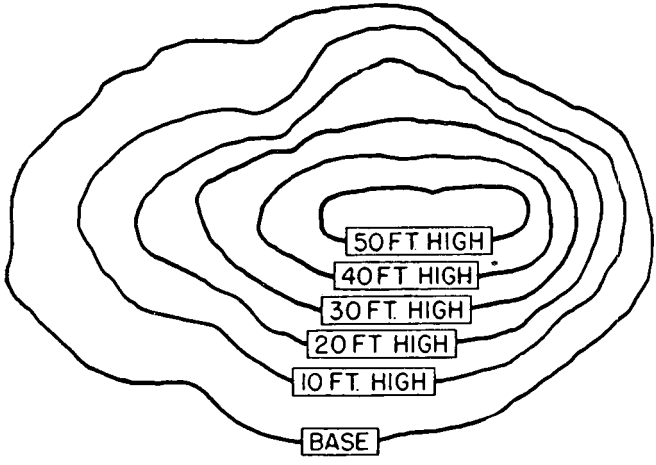

FIGURE 27.—Hill shown by contours.

(4) Contour at A, being nearly circular, indicates the top of a peak or knob, whereas the elongated contour at C indicates the crest of a sharp ridge.

(5) Though all contours are closed curves, most of those shown do not close within the limits of the map sheet. The 200-foot contour runs off the sheet at D–D and closes just

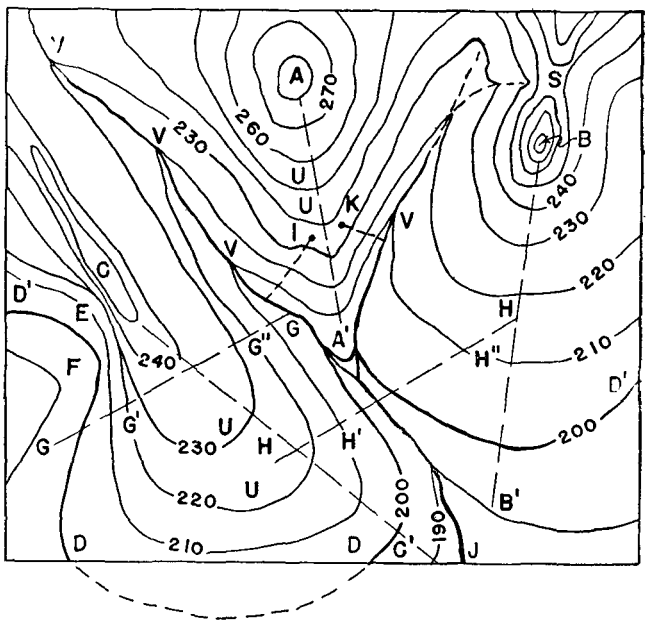

FIGURE 28.—Characteristics of contours.

outside, as indicated by the broken line. It runs off again at D'–D' and closes beyond limits of the sheet.

(6) On the line AA' there is a uniform slope. This is indicated by the equally spaced contours. On the line BB' there is a concave (sway-back) slope since the contours are close together at the top and farther apart at the bottom. On the line CC' there is a convex (humpback) slope. At B there is a steep slope while at B' there is a gentle slope.

The representation of these slopes by means of profiles is further illustrated in figure 29. (For construction of profiles see paragraph 31.)

(7) Contours do not touch each other except at E, which indicates a vertical cliff.

(8) At the points marked V is seen the characteristic V-shape of valley or streamline contours, and at those points marked U, the U-shape of ridge contours. The closed ends of the V's point upstream and those of the U's downhill.

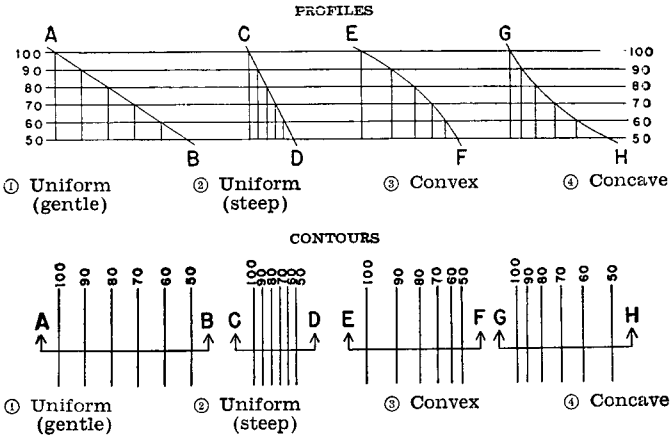

FIGURE 29.—Representation of slope by contours.

(9) At A' is shown the characteristic M-shape appearance of the contour at a Y-stream junction.

(10) Rain falling at I runs down the slope normal to the contours, entering the drainage line near G, and ultimately leaving the area by the main stream at J. The line of the spur AA' is the divide between the two tributary streams. Rain falling at K, just east of the divide, flows into the eastern tributary. The divide between any two adjacent valleys is easily traced out.

(11) Point S is a saddle, a depression or low point in a ridge or line of hills. Note the characteristic shape of the contours. Saddles occur frequently.

(12) Adjacent contours in a water-worn terrain resemble each other. This is the same as saying that changes in the form of the ground are gradual. This characteristic may be noted at many places, as on the ridge lines at AA′ and BB′.

c. Summary.—Briefly summarized, contour characteristics previously discussed and illustrated are—

(1) A contour is a line on a map joining points of equal elevation.

(2) Contours are spaced at uniform vertical intervals.

(3) A small closed contour indicates a hilltop or a depression when so marked by the conventional sign (see fig. 3).

(4) Every contour is a continuous closed curve, on or off the map.

(5) Spacing of contours indicates steepness of slopes. This spacing also indicates nature of slope, whether uniform, concave, or convex.

(6) Contours do not touch or cross each other, except in the unusual case of cliffs.

(7) Valleys are usually characterized by V-shaped contours, and ridges by U-shaped contours.

(8) Adjacent contours resemble each other.

d. Logical.—(1) Figure 30 shows the method by which a map maker draws contours on a map when he is given the drainage net and the elevations for certain critical points. Drawing of logical contours is valuable practice in gaining ability to visualize ground forms shown by contours on topographic maps.

(2) The information shown in figure 30① has been obtained by a field survey or other means. This information consists of the courses of the stream lines and elevations of selected critical points and forms the framework upon which the contour map is drawn. Consider the stream line in the lower right portion of ② running from elevation 97 to elevation 133. Elevations 100, 110, 120, and 130 are marked on this stream line by interpolation. V-marks pointing upstream are used to mark such elevations on a stream line. All other stream lines are treated in a similar manner. Contour locations are marked on the ridge lines in a similar manner, except that straight marks normal to the ridge line are used.

Marks of equal elevation are then joined producing contours as shown in ③.

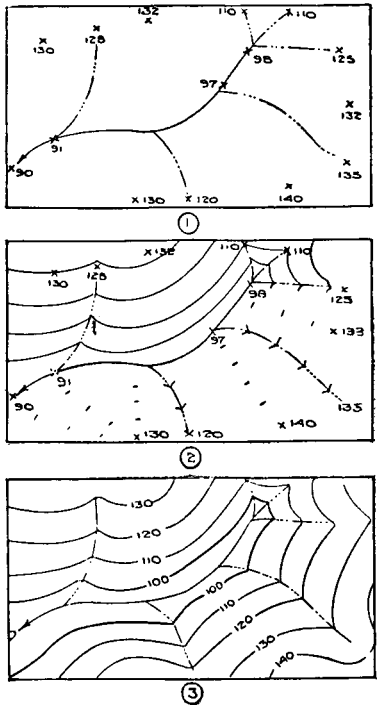

FIGURE 30.—Method of drawing contours by interpolation on drainage net where elevations are given.

■ 27. DETERMINING ELEVATION FROM CONTOURS.—Often the map reader will be concerned with some point on a map which may happen to be located between two contours, and it will be necessary to know the elevation of the point in question. If any point such as B (fig. 31) lies directly upon a contour, its elevation is of course that marked on the contour, or 580 feet in this case. But suppose the point X is not directly upon a contour. It lies between contours 580 and 590. Its

elevation is therefore something between these two figures. If a line is drawn through X perpendicular to the adjacent contours, it will cross them at A and B. Then the elevation of A is evidently 590 feet and the elevation of B 580, because these points lie upon the contours so marked. Assuming the ground falls uniformly from A to B, without making any measurement of the distance BX, it can be judged by eye that it is a little more than half and a little less than two-thirds of the distance AB. It may be said without any great

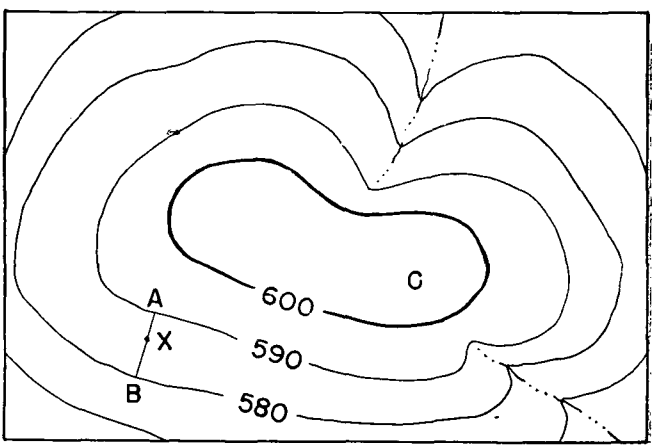

FIGURE 31.—Determining elevation from contours.

error that it is 0.6 of AB. The difference of elevation of A and B is 10 feet. Hence the elevation of X is 580 plus 0.6 of 10 feet or 586 feet, giving an error probably less than 1 foot. This determination is close enough for the map reader. It is not necessary to draw such a line as AB or to measure a distance such as BX. If the point Y is taken it can be said by merely looking at it that its elevation is 588 feet. In case the point in question lies on the top of a hill such as C, only an approximation is possible. The elevation of C is greater than 600 but not as much as 610 since the 610 contour is not shown. Often the exact elevation of the highest points on hills will be given.

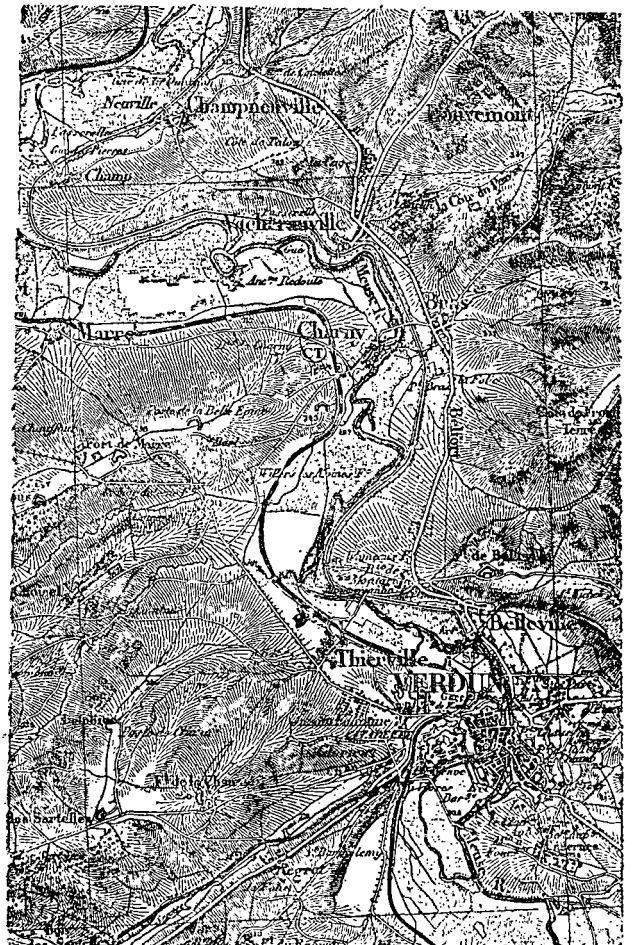

FIGURE 32.—Hachure map.

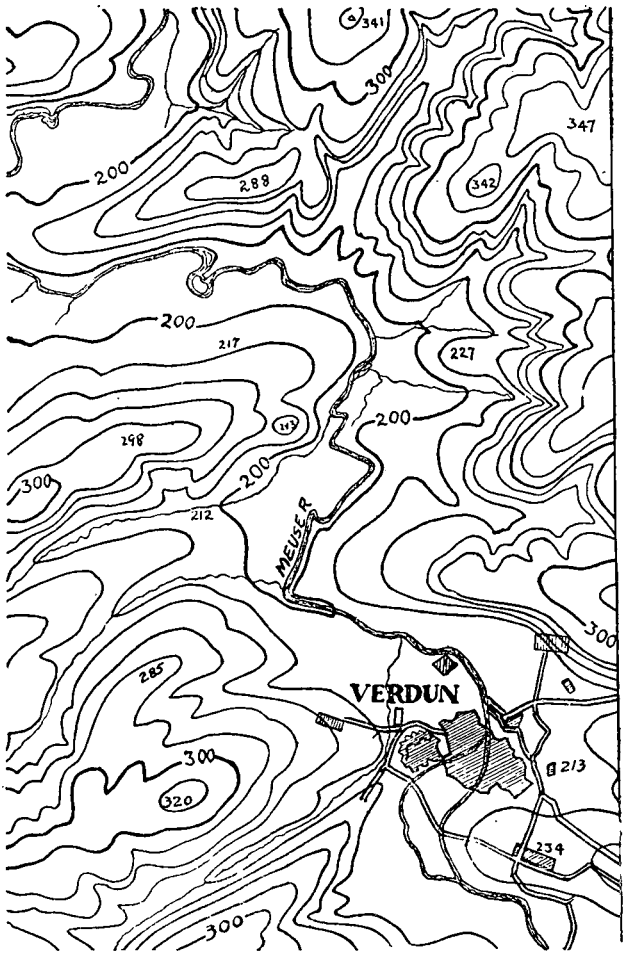

FIGURE 33.—Contour map of same area as hachure map in figure 32.

■ 28. HACHURES.—Frequently on foreign maps, a method of representing elevations called hachuring is used instead of contouring. Hachures consist of short lines running directly down the slopes of hills, that is, they show the direction that water would flow downhill. Hence, hachures are at right angles to contours. Steepness of the slope is indicated by thickness and spacing of the lines; steep slopes are shown by heavily inked lines very close together, while lightly shaded lines wide apart show gentle slopes, and level areas are left without any lines whatever. Hilltops, ridges, valleys, and various slopes are easily recognized from hachures but specific elevations cannot be determined accurately unless given in figures. The contour method is better for military purposes. Figures 32 and 33 show the comparison between a hachured and a contoured map.

■ 29. RIDGE LINING AND STREAM LINING.—*a. Purpose.*—In order to emphasize the basic structure or master lines of the terrain of a given area, a system known as ridge lining and stream lining is often used. On a map or an aerial photograph thus ridge lined or stream lined, the great mass of detail which may tend to confuse may be neglected for the moment, and those basic structures such as stream systems, ridge lines, and key features can be emphasized. Three steps may be followed in this process.

b. Stream lines.—Study the map or aerial photograph and select the main streams and their tributaries. Emphasize them, preferably by drawing over them in blue, and thus cause the drainage system to stand out.

c. Ridge lines.—Draw a line down the main ridges. This should be done preferably in brown so as not to obscure features lying under the lines. Then select the minor ridges and trace their ridge lines in a similar manner. The number of minor ridges to be included will depend upon the emphasis desired. In drawing ridge lines it is not normal to carry them all the way to the stream. A good system is to stop at the beginning of the flood plane as shown by the increase in space between contours. It will be noted that the tendency at first is to mark isolated ridges, whereas the ridge lines should form a connected structure. If all the ridge lines in

an area are drawn, it usually will be found that they join together into a systematic branching structure like the fingers of a hand or the backbone and smaller bones of a fish. This structure is similar also to the branches of streams; in fact

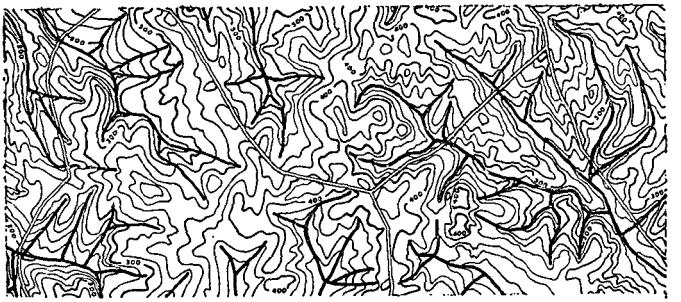

FIGURE 34.—Contoured map with stream lining.

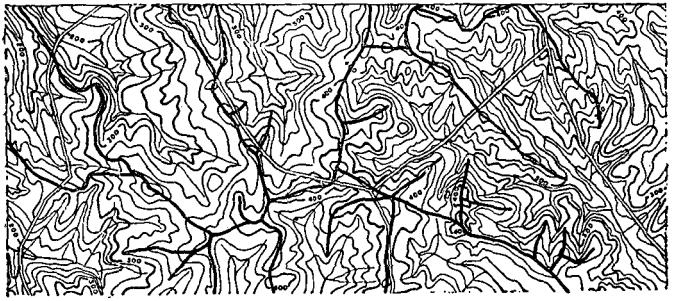

FIGURE 35.—Contoured map with ridge lining.

the branches are fingers of the two systems fitted into each other. Ridge lines do not cross streams. Figure 34 shows a portion of a contour map which has been stream lined; figure 35 shows this same area after it has been ridge lined. Note how the main drainage system and the main ridge lines stand out.

d. Emphasized contours on contoured maps.—Certain contours may be emphasized by use of thicker lines, and it is customary to do this at regular intervals to facilitate the reading of contour maps; for example, on map in figure 1 (back of manual), thicker lines are used at 100-foot intervals. Likewise, commanding elevations may be brought out by coloring the map area between selected contours.

■ 30. SLOPE AND GRADE.—*a. General.*—Slopes and grades are important to the map reader since they affect selection of

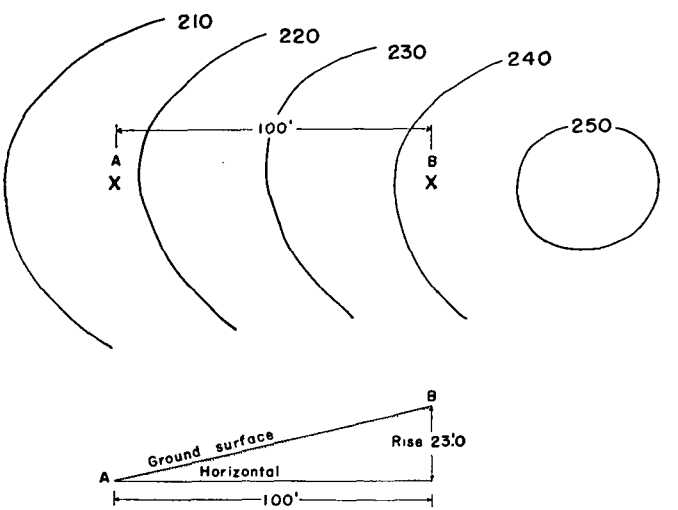

FIGURE 36.—Determination of slope.

routes of travel whether by road or open country, and siting or location of all military works and weapons. In paragraph 26*b* it was learned that the spacing of contours indicates the slope of the ground. A step further is to determine from a study of contours on maps the amount of slope and express it numerically. There are several methods of expressing

slopes of ground surfaces. The method of expressing slope by percent is the principal one and the only one that will be described in this manual.

b. Slope in percent.—A slope of 1 percent is one in which 1 foot of vertical height is ascended or descended in traveling 100 feet of horizontal distance. A slope of 10 percent is one in which 10 feet are ascended or descended in traveling 100 feet. Thus in figure 36 where AB represents a slope, if the horizontal distance from A to B is 100 feet, and difference of elevation is 23 (or 242—219) feet, the slope of AB$=\frac{23}{100}=23$ percent. An upward slope is plus, a downward slope minus, that is, the slope from A to B is plus 23 percent, but from B to A is minus 23 percent.

c. Grade.—The slope of road and railroad lines is referred to as grade, and may be computed in a manner similar to that described in *b* above.

■ 31. PROFILE.—*a. General.*—The most satisfactory way of showing the slope of any line on a map is by drawing its profile. A profile between two points is the line (usually irregular) of intersection of an imaginary vertical plane cutting the earth's surface between these two points. For example, in figure 37 imagine a vertical plane passed from above through the earth between the points A and B, and the front half of the hills and ridges removed, just as a cook passes a knife through a cake and removes half. The outline of the surface of the remaining half would be its profile as represented in figure 37②. It has already been seen in figure 29 how profiles may be used to illustrate the different types of slopes indicated by the spacing of contours. Profiles are also a means of determining the visibility or the defilade of points or areas from any selected point on a map. Visibility is discussed in paragraph 32.

b. To draw profile between two points.—Figure 37① represents a portion of a contoured map. It is desired to construct the profile of the ground represented by the map between the points A and B. Proceed as follows:

(1) Connect points A and B by a straight line and assume that a vertical plane is passed through this line.

(2) Take a piece of cross section paper or any paper which has parallel lines equally spaced; cut or fold the paper along one of these lines.

(3) Refer to map and determine the highest and lowest elevation along the line AB; number the spaces on the paper

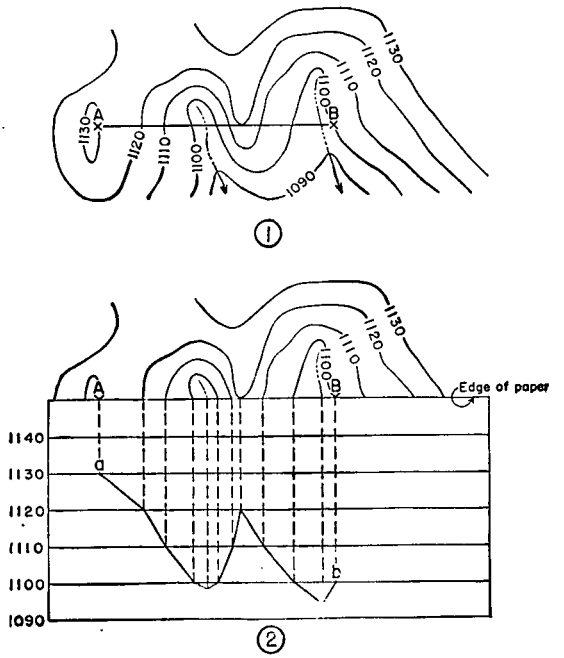

FIGURE 37.—Construction of a profile.

to correspond with the elevations on the map beginning with the highest elevation toward the top edge of the paper (fig. 37②).

(4) Place top edge of the paper along the line AB and where the edge cuts each contour, drop perpendiculars to the line on the paper corresponding to the elevation of the contour being considered.

(5) Connect the points of intersection of the perpendiculars with the lines of the paper. This will represent the profile except between adjacent contours of the same elevation which require the determination of intermediate elevations.

(6) Where the line crosses a crest or a depression an elevation number on the map is sometimes found to assist in completing the profile. Where such elevation numbers are missing, interpolate necessary elevations from the spacing of the contours, using the method described in paragraph 27.

(7) When a profile is desired of an irregular line on the map, such as a road or trench, divide it into a series of sections approximately straight and plot as directed above, turning the paper at each angle to make a continuous profile.

c. Vertical scale.—Profiles usually have an exaggerated vertical scale in comparison with the horizontal scale which ordinarily is the same as that of the map as shown in figure 37②. In the figure, the lines on the paper could represent 10-foot elevations as indicated, or they could represent 5-foot elevations, thus further exaggerating the profile as desired. For constructing profiles, use of cross section paper will be found most convenient since the vertical lines assist in dropping the perpendiculars to the horizontal lines representing the contour elevations.

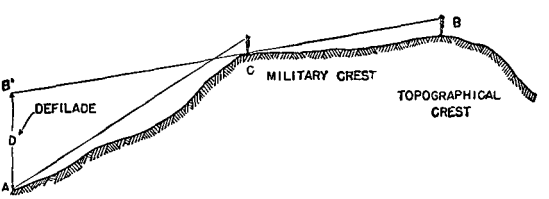

FIGURE 38.—Defilade.

■ 32. VISIBILITY.—*a. General.*—One of the important uses of maps for military purposes is to determine whether a point, a route of travel, or an area is visible from a given point or position. The extent of the area visible affects selection of targets, siting of weapons, and location of defiladed area or dead space (fig. 38). There are various methods of solving visibility problems, but only the ones more commonly used will be covered in this manual.

b. Inspection.—Many problems of visibility may be solved by inspecting the map, and determining from the contours the ground slope represented. The representation of ground slopes by contours is described and illustrated in paragraph 26*b*. For example, in figure 29 it is evident by

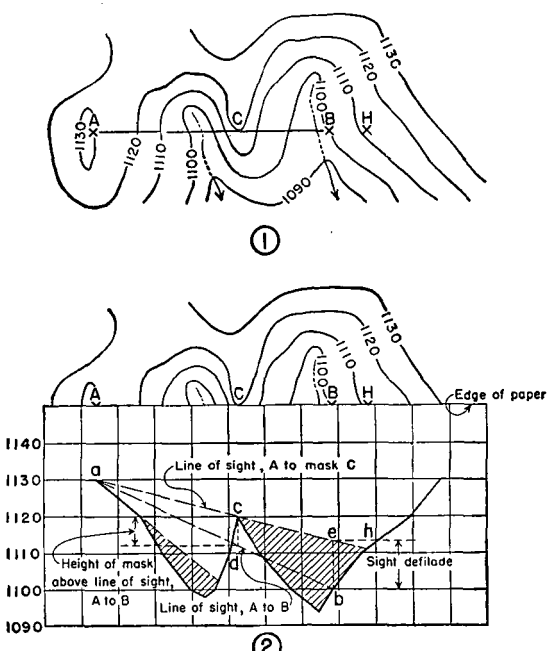

FIGURE 39.—Determination of visibility by profile method.

inspection that an observer at E cannot see the ground at F, this being a convex or humpback slope, while an observer at G can see the ground at H, this being a concave or sway-back slope.

c. Profile.—In paragraph 31 it was learned how to construct a profile between two points such as AB on figure 37. Suppose it is required to use the profile method to

determine what points along the line AB are visible from an observer at A. Construct a profile along the line AB as described in paragraph 31. It is evident in figure 39 that

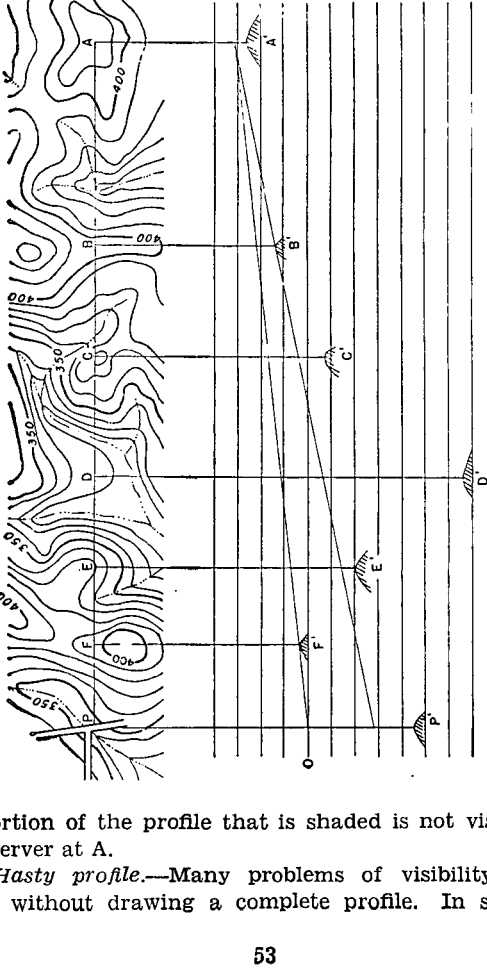

FIGURE 40.—Determination of visibility by hasty profile method.

the portion of the profile that is shaded is not visible from an observer at A.

d. Hasty profile.—Many problems of visibility may be solved without drawing a complete profile. In such cases

only the critical points which may affect the visibility are plotted, such points being first determined by inspection. These points would be the position of the observer's eye, the probable masks (hills or ridges), and the point where visibility is to be determined. This is illustrated in figure 40 which represents a portion of a contoured map. It is required to determine what an observer can see along the line AP from various points along this line, assuming trees and other vegetation do not interfere. It is evident that while at A the observer can see only point B and point F. From B he can see A, C, E, and F, but is unable to see points D and P. This can be continued for other points.

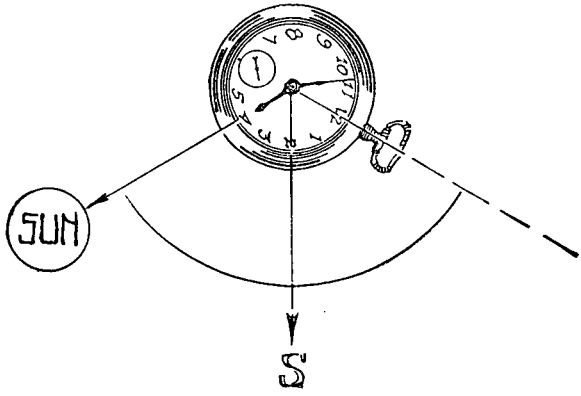
SECTION VII

MAP READING IN THE FIELD

■ 33. GENERAL.—All Army personnel should keep in mind the importance of being able to read maps accurately and quickly in the field. Many disastrous mistakes have resulted from a lack of ability to read maps. To be able to read a map properly in the field, the student should be familiar with all material covered in the preceding sections. He should keep in mind that the map and aerial photograph are often the only means available for studying distant or inaccessible areas. He should always take his map into the field with him and constantly refer to it. He should keep his movements plotted on it, especially when operating over unfamiliar territory, and verify his location at every opportunity. He should practice until it is possible for him to secure a clear and accurate picture of the ground from the information given on the map. In addition to material in preceding sections, a few aids to his map reading ability are orientation, use of compass, determination of distance, and names by which ordinary features of the ground are known. A brief description of each of these follows.

■ 34. ORIENTATION.—*a. General.*—A person is said to have oriented himself when he stands on the ground and knows the cardinal directions north, south, east, and west. A person is oriented with respect to a map when he knows his position on that map, and a map is oriented when in a nori-

zontal position its north point actually points north. Every stream, road, or other feature on the map is then parallel to its true position on the ground, making it comparatively simple to pick out on the ground objects represented on the map. One who is responsible for guiding by map must know his position on it by constant reference to the map. Normally a map reader can keep himself and his map oriented by observing familiar landmarks. When such marks are not



Point hour hand at sun; south is half-way between hour hand and 12 on the dial.

FIGURE 41.—Method of determining direction by watch and sun.

available, the sun, stars, and compass may be used. Figure 41 shows an approximate method of finding south by use of the sun and an ordinary watch showing correct time. Figure 42 shows a method of finding the North Star by use of the pointer stars in the Big Dipper.

b. Method of map orientation.—(1) *Inspection.*—Figure 43 shows how a map may be oriented by carefully observing road system and features in immediate vicinity. It will be noted that the map has been rotated horizontally until the road on the map parallels the road on the ground, care being used to see that positions of nearby ground features are in similar relation to their corresponding conventional signs as shown on the map. This is the most practical method for ordinary

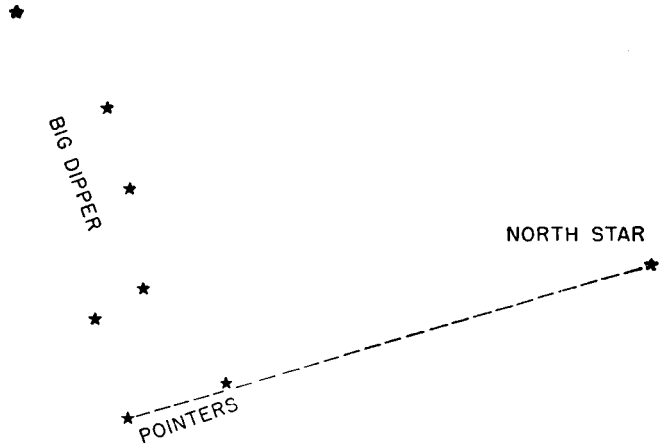


FIGURE 42.—Determining north by use of Big Dipper and North Star.

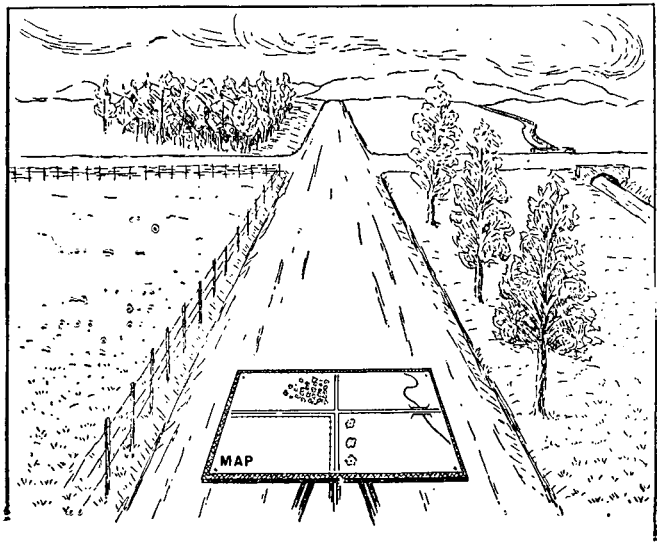

FIGURE 43.—Orienting map by inspection.

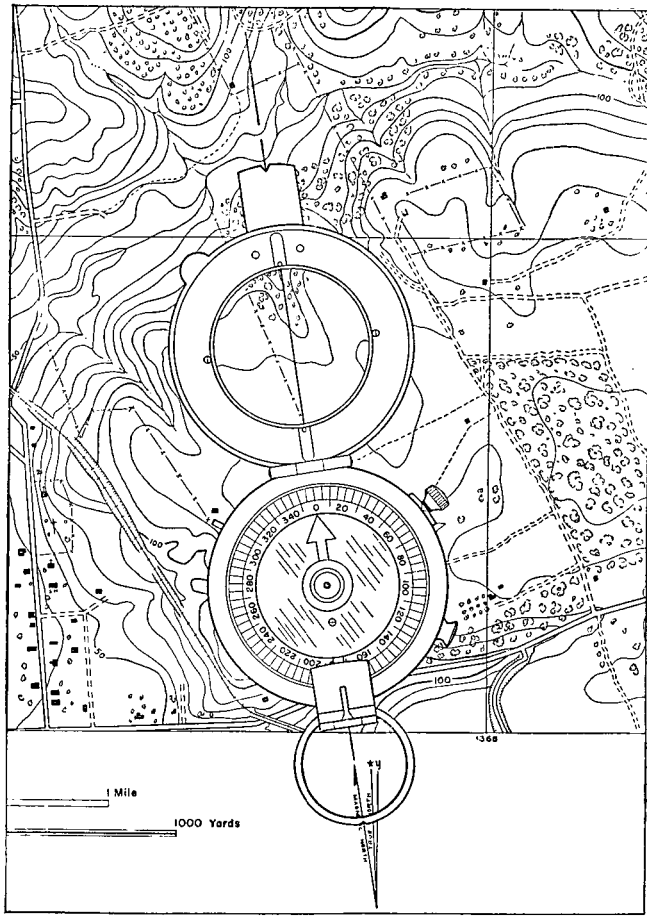

FIGURE 44.—Orientation of map by compass.

purposes and may be used as a rough check on more accurate methods.

(2) *Compass.*—Magnetic north is shown on most maps and is also indicated in the field by the north end of the compass needle. Figure 44 illustrates use of this method. Either

prolong magnetic north line or draw a line parallel to it. Then place compass on map with north point of compass case on this line. Rotate map horizontally until north end of needle coincides with north point of the case. Map is now oriented.

(3) *By means of a distant point when observer's position is known.*—A third method of orientation where a compass is not available and where there are no nearby features suit-

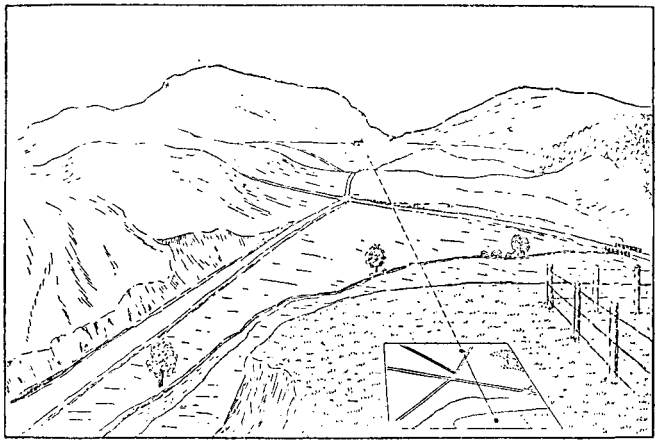

FIGURE 45.—Orienting map by means of distant point.

able for orientation by inspection is illustrated in figure 45. Place a pin at observer's position on map. This may be found by reference to the fence corner (fig. 45). Place another pin on the map location of some well-defined point such as the church. Holding map horizontal, sight at church on the ground along the line of pins. Map is now oriented. A more precise orientation is secured if more than one point can be used. Once the map is oriented, approximate map location of a target or other point may be determined as follows: keeping map in oriented position, sight over pin at observer's position toward designated point and place a pin on line of

sight. From a study of the map or by estimation or measurement of the distance, fix location of the point.

■ 35. FINDING OBSERVER'S POSITION ON MAP.—*a. Inspection.*—If approximate location on a map is known, all the observer has to do is study visible terrain for distinctive features and his position can be found by identifying these features on the map. This procedure is greatly simplified if the map is oriented to the ground. Figure 46 is an example of this method.

b. Striding or estimation of distance when along road, railroad, etc.—This method is illustrated in figure 47. Briefly, the method is to identify on the ground the nearest road bend, road junction, bridge, etc., which appears on the map, such as B in figure 47. The distance to this point is either estimated or measured by striding and position on map is obtained by laying off distance AB to scale of map as indicated in the sketch.

c. Resection from two known points.—This method is illustrated in figure 48. First, orient map accurately. Look over terrain and select two distant visible features on the ground, B and C, which can be located and identified on the map, b and c. Features selected should be so located that lines radiating from observer to them form an angle of as near 90° as possible. Place a pin in b, lay a straightedge (ruler or pencil) against the pin, turn it until it points at B. Draw a ray on the map from the pin toward observer's position. Repeat the same operation with point c. Intersection of the two lines is observer's location on map. Care must be exercised that map remains oriented during entire procedure. If three points are used instead of two, observer's location will probably be more accurate.

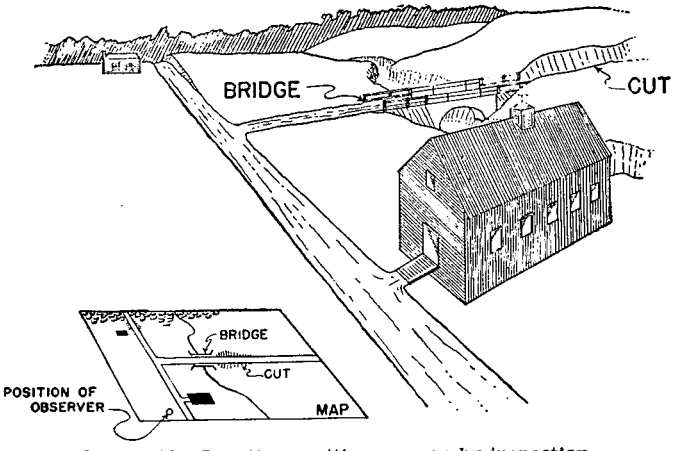

FIGURE 46.—Locating position on map by inspection.

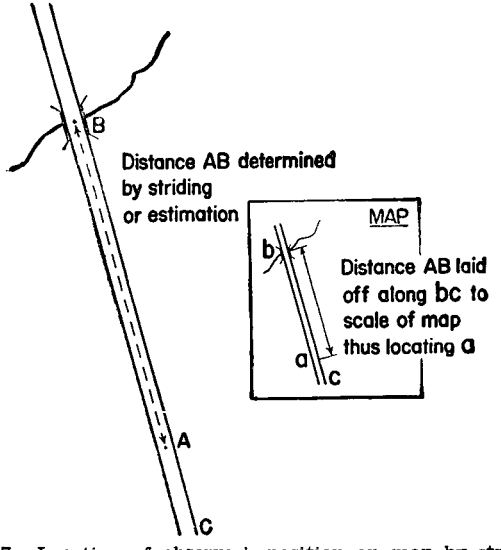

FIGURE 47.—Location of observer's position on map by striding or estimating distance when along road.

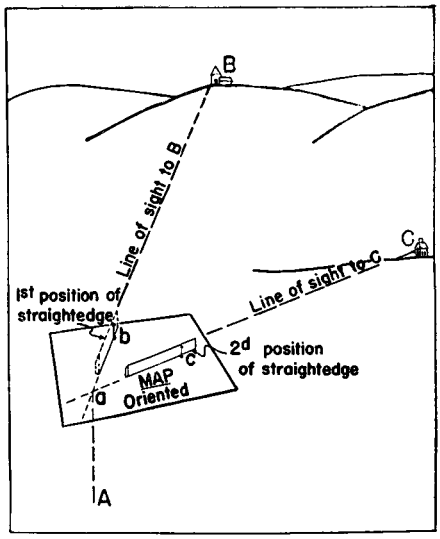

FIGURE 48.—Location of observer's position on map by resection from two distant points (graphic method).

■ 36. MILITARY TERMS FOR TERRAIN FEATURES.—In addition to usual standard terrain terms such as hill, ridge, valley, etc., certain other words are used to describe features of military importance. The most common of these are shown in figure 49.

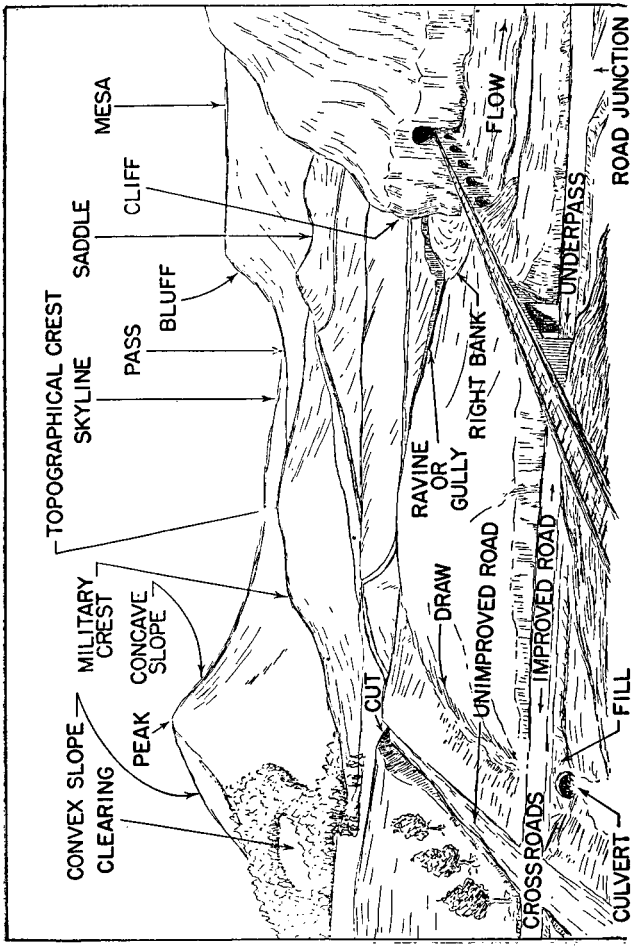

FIGURE 49.—Military features of terrain.

■ 37. DISTANCE.—There are many means of measuring distance. When time is not essential or conditions not unfavorable, pacing or even taping may be used. Along roads measurement of distance by speedometer mileage will be very common. For dismounted troops and for objects off route of travel for motorized troops, distances normally will be estimated by eye. All personnel should practice until they acquire reasonable skill in estimation by eye. However in some conditions, for example, night patroling or marching over broken terrain, all such methods are impracticable. For such operations two other methods may be used. In one, the leader can scale off the distance he must travel on his map and then locate and identify some prominent terrain feature at the end of his march. He has then merely to keep going until he comes to this feature. In the second method, he can reduce distance to time. Since the normal marching rate is 1 mile in 20 minutes, this reduction is very simple. If he is sent down the road a distance of 2 miles, he has merely to walk for 40 minutes and he should be near or at his destination.

■ 38. COMPASS.—*a. Types.*—The three types of compass issued in the service are prismatic, lensatic, and watch. The watch compass shown in figure 8 is being replaced by the lensatic compass. Descriptions of the other two types are given below.

(1) *Prismatic.*—The prismatic compass is shown in figure 50② showing the more important parts labeled. It consists of a case containing a magnetic dial (b) balanced on a pivot, a hinged cover (d) with a glass window, a holding ring (e) and an eyepiece (a) containing a prism for reading graduations on the dial. The dial has two scales, the outer scale to be read through the prism or eyepiece and the inner to be read directly. Both scales are graduated from 0° to 360°. The north point is indicated by an arrow of luminous paint. The glass cover has an etched line (f) which may be used like a front sight, and the eyepiece (a) has a slot that may be used as a rear sight. In case the window in this cover is broken, a horsehair or a fine wire can be threaded through and stretched between the two holes in the cover provided for that purpose. Closing the lid operates a lever (g) which raises the dial to protect the compass from injury when not

in use. To lower the dial push clamp (g) forward with the thumb. A second glass protects the face of the dial when the lid is raised. On it is painted a luminous movable index which is used to set angles from the line of sight or north point. This glass can be revolved by unlocking the set screw (h) and turning the corrugated brass ring so that the movable index points at any angle from the line of sight. It can then be set at this angle by tightening the set screw (h). A rubber washer is fixed to the bottom of the case to prevent slipping when laid on smooth objects. The compass is carried in a stout leather case with a belt loop. The outside of the brass case is marked with two scales, one to read azimuths, and the other to read compass directions. Figure 52 shows one use of this outside scale. The compass is affected by presence of iron, steel, or electricity, and will not give accurate readings near an automobile, tank, fieldpiece, machine gun, or power line. A steel helmet, rifle, or pistol on the person of

j-j' Luminous marks on cover

② Parts labeled.

FIGURE 50.—Prismatic compass—Continued.

the observer may influence the needle and make readings inaccurate.

(2) *Lensatic.*—Figure 51 shows two views of a lensatic compass. It functions in much the same manner as the prismatic compass. The hinged eyepiece is a narrow piece of metal containing a magnifying lens in the larger circular opening. When the eyepiece is tilted so that it is aimed at the forward part of the compass face, the observer is able to see both the scale and a distant point at the same time. It should be noted that the face has two scales, the outer

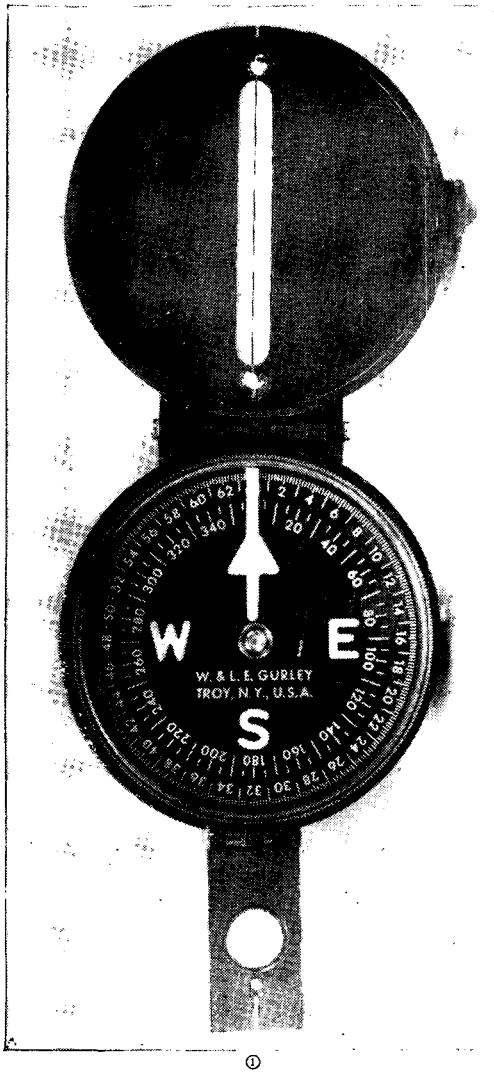

FIGURE 51.—Lensatic compass.

②

FIGURE 51.—Lensatic compass—Continued.

one showing mils, and the inner one showing degrees. The compass is made of light aluminum and is designed so that it may be carried in a pocket.

b. Measuring azimuth with prismatic compass.—To read the azimuth to any point proceed as follows (fig. 50②):

(1) Raise cover (d) and eyepiece (a) vertically, and lower needle dial at (g).

(2) Hold compass horizontally in front of the eye and pointing in the direction of object azimuth of which is desired. In doing this utilize every possible means for holding compass and eye steady. Methods used are somewhat similar to those used for sighting a rifle. A good method is to rest

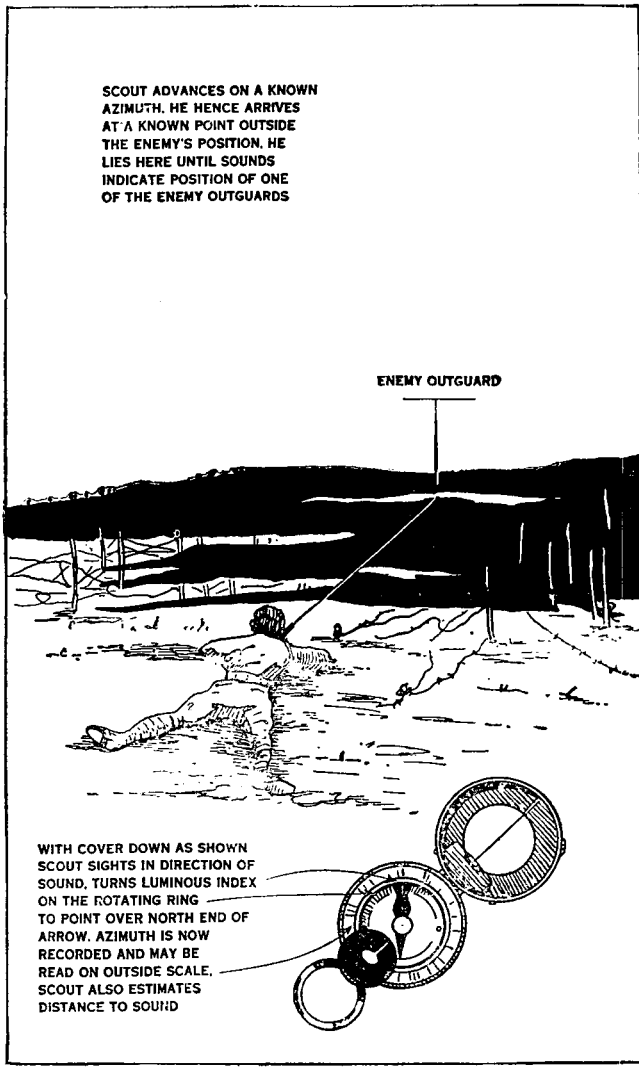

FIGURE 52.—Use of compass dial.

head, wrist, and body against a good substantial tree or other nonmetallic object. A prone or sitting position similar to that assumed for firing a rifle is also suitable. The dial may be dampened by operating the plunger (i) with index finger of left hand.

(3) Sighting through slot in eyepiece, line up object with etched line (f) in cover. Hold compass steady until dial comes to rest. Read azimuth indicated on dial as seen through eyepiece. This will be the magnetic azimuth of the line from observer to object.

c. Marching by compass.—(1) *Day.*—Often troops are ordered either to march or attack cross country according to given azimuths. Such troops might include patrols or individuals on scouting or messenger missions. Patrol leaders or unit commanders may compute from a map azimuths of various legs of their routes to prevent getting lost. Map azimuths must then be converted to magnetic azimuths before they can be used with the compass. Having determined this magnetic azimuth, the leader holds his compass steady and turns it until required azimuth is read on the dial (fig. 53). He then sights along axis of the compass as described in *b*(3) above and selects a house, tree, rock, or other easily recognizable feature of the landscape on this line of sight. He then marches toward this selected feature until he reaches it or loses sight of it. He then takes another sight as described above and selects a new feature. This is repeated until he reaches his destination. Note that the compass is used to select successive features on the line of march and is not used when actually marching.

(2) *Night.*—For marching at night, movable index (c), luminous marks (j–j') on inside of cover, and azimuth scale on outside of case are used (fig. 50②). To march on given azimuth at night, set movable index at desired azimuth, rotate compass until needle points at movable index, and then select some feature on the skyline that is on the axis of the compass. March toward this selected feature. The axis of the compass can be determined by means of the luminous marks (j–j'). Setting the compass must be done in the light, usually by flashlight, screened from observation. On

very dark nights where the skyline is not visible, it may be necessary to send one man ahead to the limit of visibility, line him up on desired azimuth, and then walk toward him, repeating this as often as is necessary.

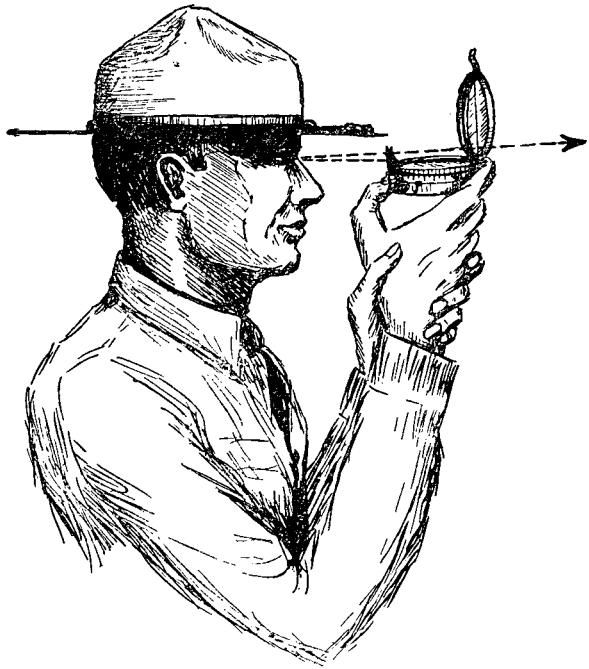

FIGURE 53.—Prismatic compass open and in position for measuring azimuth in daylight.

SECTION VIII

AERIAL PHOTOGRAPH READING

■ 39. GENERAL.—*a. Importance.*—Aerial photographs are used for many different purposes in connection with military operations. In this manual they are considered primarily in conjunction with or as substitutes for topographic maps. The

ideal situation is to have an accurate topographical map and a recent aerial photograph of the same area. During the first few days or even weeks in a new theater of operations there is a great possibility that the only up-to-date information of the terrain available would be that obtained from aerial photographs. They would be used in determining distances and directions, and in selecting routes in much the same manner as ordinary topographic maps.

b. Types.—(1) Vertical photographs are those made when axis of the camera is kept as nearly vertical as possible.

(2) Oblique photographs are those made when axis of the camera is deliberately tipped from the vertical.

(3) Composite aerial photographs are made with cameras having one principal lens and two or more surrounding and oblique lenses. The several resulting photographs are corrected or transformed in printing so as to permit assembly as verticals with the same scale.

c. Marginal data on aerial photographs.—(1) As aids in reading and use, aerial photographs used for photomaps will have information along the black strip at the bottom, reading from left to right, as follows:

(*a*) An arrow one-half inch in length in the lower left hand corner of the negative indicating north, with letter N superimposed over center of shaft.

(*b*) Name of locality or nearest locality.

(*c*) Approximate military grid coordinates of center of photograph.

(*d*) Scale of photograph expressed as a representative fraction in case of a vertical, altitude above ground in feet and focal length of camera in case of an oblique.

(*e*) Hour.

(*f*) Date arranged in the following order: day, in figures; month, in letters; and year, in figures.

(*g*) Designation of squadron.

(*h*) Serial number of negative. In additon to a north point, the following is the legend on a vertical:

Saranac, N. Y.—(321–437)—1:20,000—(2:00 P.M.)—(24–Aug–40)—97th—M5. (See fig. 62.)

(2) Mosaics and wide coverage photographs may have in addition to that listed above the following information:

(*a*) Marginal information similar to that shown on maps such as the graphic scale in yards.

(*b*) Some system of grids, preferably the atlas grid described in paragraph 44.

(*c*) Names of important features such as towns, streams, mountains, highways, etc.

■ 40. OBLIQUE.—Normally in making obliques the photographs are taken over the side of the cockpit with the camera.

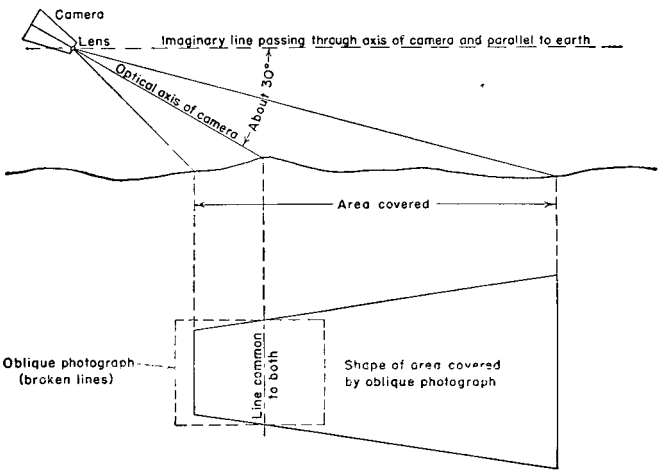

FIGURE 54.—Relative shape of area covered by oblique photograph compared to photograph itself.

intentionally tilted at an angle which will vary according to the mission, but is usually about 30° below the horizontal as shown in figure 54. This procedure gives what is known as a low oblique (fig. 55). Obliques which include the horizon are termed high obliques (fig. 56). Figure 54 also shows the relative shape of the area covered by an oblique photograph as compared to the photograph itself. Note the actual photograph is a rectangular print whereas the area covered by the photograph has the shape of a trapezoid and is much larger. Distances on oblique photographs cannot be scaled

①

FIGURE 55.—Low oblique.

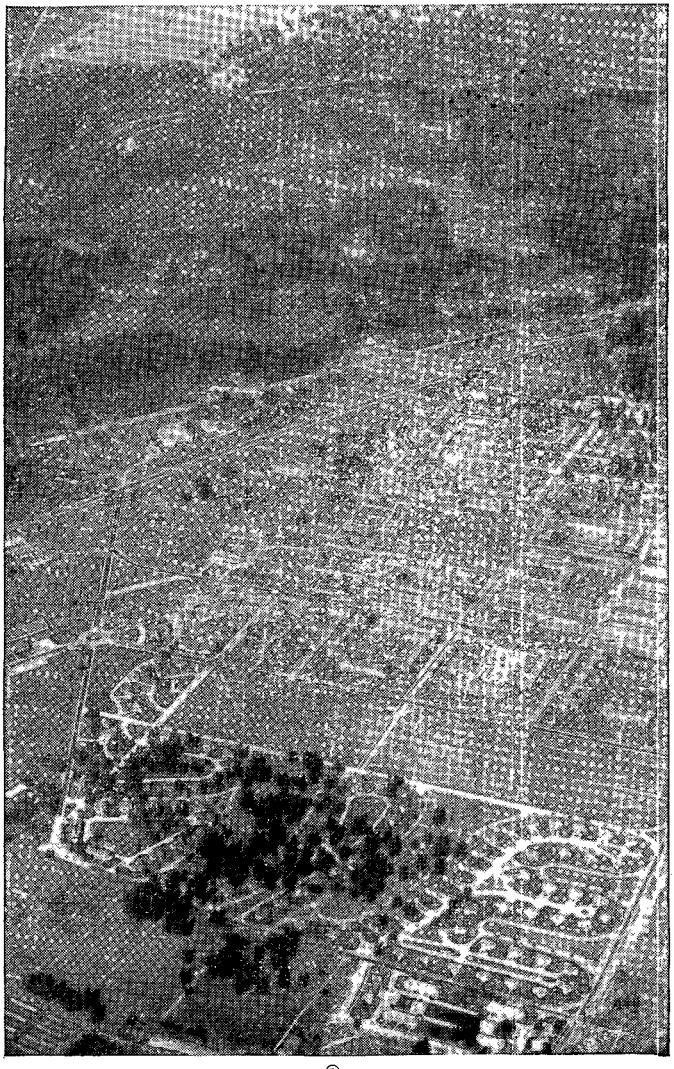

FIGURE 55.—Low oblique—Continued.

FIGURE 56.—High oblique.

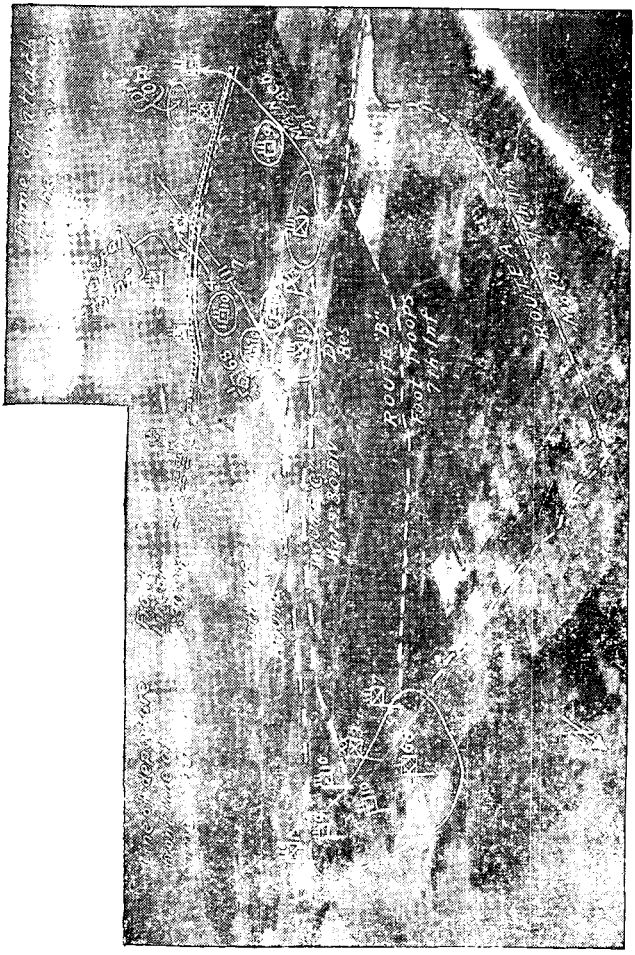

FIGURE 57.—Oblique photograph used as map substitute to accompany oral field order.

accurately. However, since the oblique picture is taken from a viewpoint similar to that of an observer on a high hill, terrain features have a more normal appearance than they do in a vertical; this characteristic makes them more useful for the study of hills, valleys, buildings, roads, etc. They can also be used to accompany operations or field orders. As shown in figure 57 it is possible to show the line of departure, routes from bivouac to assault positions, assembly positions, boundaries between units, objectives, and information of the enemy.

■ 41. VERTICAL.—Vertical photographs are usually taken through an opening in the floor of the airplane cockpit perpendicular to the surface of the earth. Each photograph covers a comparatively small ground area and shows the area somewhat as it would appear on a detailed map or sketch of similar scale. Figure 58 shows photographs taken from different altitudes of the same general area. Scale (RF) of each is given below it. Obliques of the area are shown in figure 55. Comparison of the areas covered for different scales should be made the subject of careful study. Figure 1 (back of manual) has these same areas outlined in heavy black lines. Learning to read a vertical photograph is similar to learning to read a map. It consists in being able to recognize familiar objects on the landscape from their appearance on the photograph, to orient the photograph, to determine its scale, and to determine distance and direction. A photograph however is not as easy to read as a map. Important features on a map are emphasized and always are shown in the same manner. On a photograph important features such as roads, railroads, bridges, and streams may appear less important than a great amount of unimportant detail, or may be completely hidden by trees or shadows. Dissimilar objects such as roads, railroads, and canals may look alike, and the same objects may appear to be different on various photographs or even on different parts of the same photograph. Also, a single vertical photograph unlike a topographic map contains no definite information of ground forms and elevations. Hills, ridges, and depressions are difficult to visualize unless an analysis of the drainage system within the area is made. Even

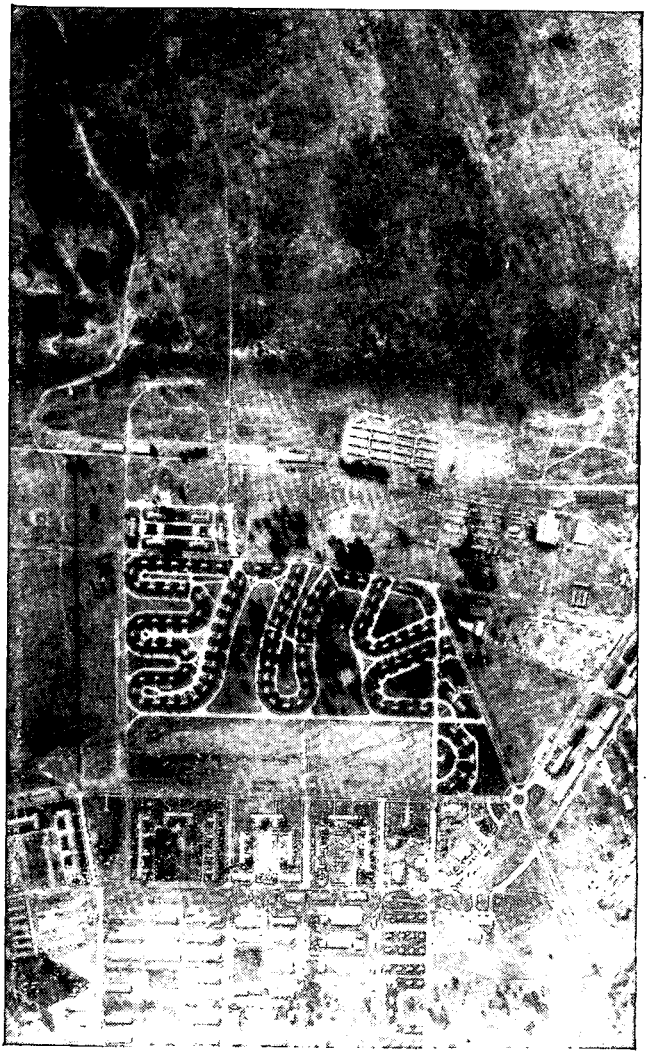
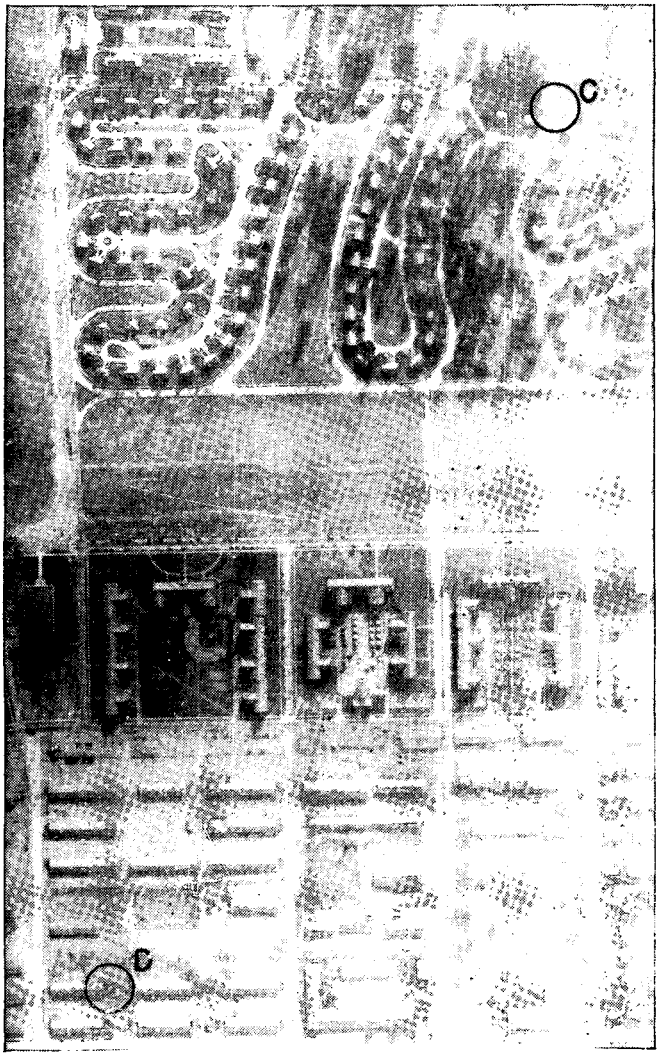
FIGURE 58.—Vertical photograph.



⊙ Scale, 1:16,000 (approximate).
FIGURE 58.—Vertical photograph—Continued.



③ Scale, 1:7,813.
FIGURE 58.—Vertical photograph—Continued.

when this is done relative elevations are not apparent on the photograph. On the other hand, an aerial photograph is very valuable for the reasons that it—

a. Possesses in pictorial form a wealth of detail which no map can equal.

b. Can be prepared for use in a short time, much quicker than making a new map.

c. Is up to date.

d. Can be made of any area, even those inaccessible to ground mapping parties.

■ 42. IDENTIFYING TERRAIN FEATURES.—*a.* Identifying features of terrain on photographs requires a certain amount of practice which is best gained by actually comparing the photograph with the ground. When this is not possible, the next best method is to compare photographs with a good map of the same area. Actual identification of objects on an aerial photograph or on a mosaic is effected through one or more of the following means:

(1) Shape of object.

(2) Its tone, or relative colors from white through various shades of grey to black.

(3) Shadow it casts.

(4) Apparent or relative size.

b. In identifying features always hold the picture so the shadows are falling toward the body. Figure 59 shows several ground features numbered to correspond to the numbers of the subparagraphs below containing their description. When reading the description, look at figure 59 and note how reasons given for each identification apply.

(1) Plowed field looks light in the photograph because it reflects a relatively large amount of light.

(2) Meadow looks darker largely due to the shadows of the grass. The meadow is said to have more texture than the field. The difference between the meadow and the field is similar to the difference between satin and plush velvet. Although both are the same color, the plush looks darker due to the shadows of the hairs which stand erect, but it can be made to look lighter when smoothed down.

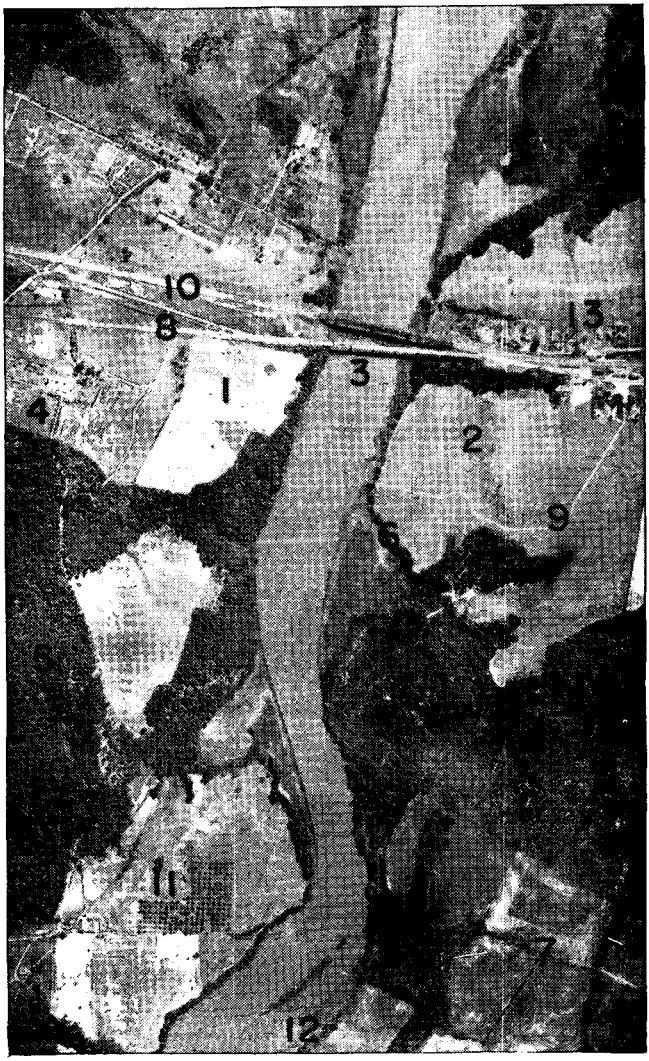


FIGURE 59.—Identification of terrain features.

(3) Bridge looks lighter than the water. It can be identified by its size, shape, and its shadow on the stream.

(4) Building can be identified by its size, shape, difference in appearance of the two roof slopes, and by its shadow. The shadow looks darker than the building.

(5) Woods appear relatively dark because of deep shadows of the trees. They have much texture and reflect little light.

(6) A stream can be identified by its meandering course. Even through open fields some trees or bushes usually grow along its banks. In a dense wood it will appear as a thinning out of the surrounding growth. The water looks very light or dark, depending upon the relative positions of sun, camera, and water.

(7) Fence lines are identified by difference in texture between fields they separate and usually look dark in the photograph because of shadows of bushes growing along them.

(8) Roads are identified by their straight lines, uniform width, and the fact that their surfaces are usually smooth and reflect much light. (Modern open asphalt texture surfaces will appear darker than other road surfaces.)

(9) Trails are also light but are more variable and narrow in width and more crooked than roads.

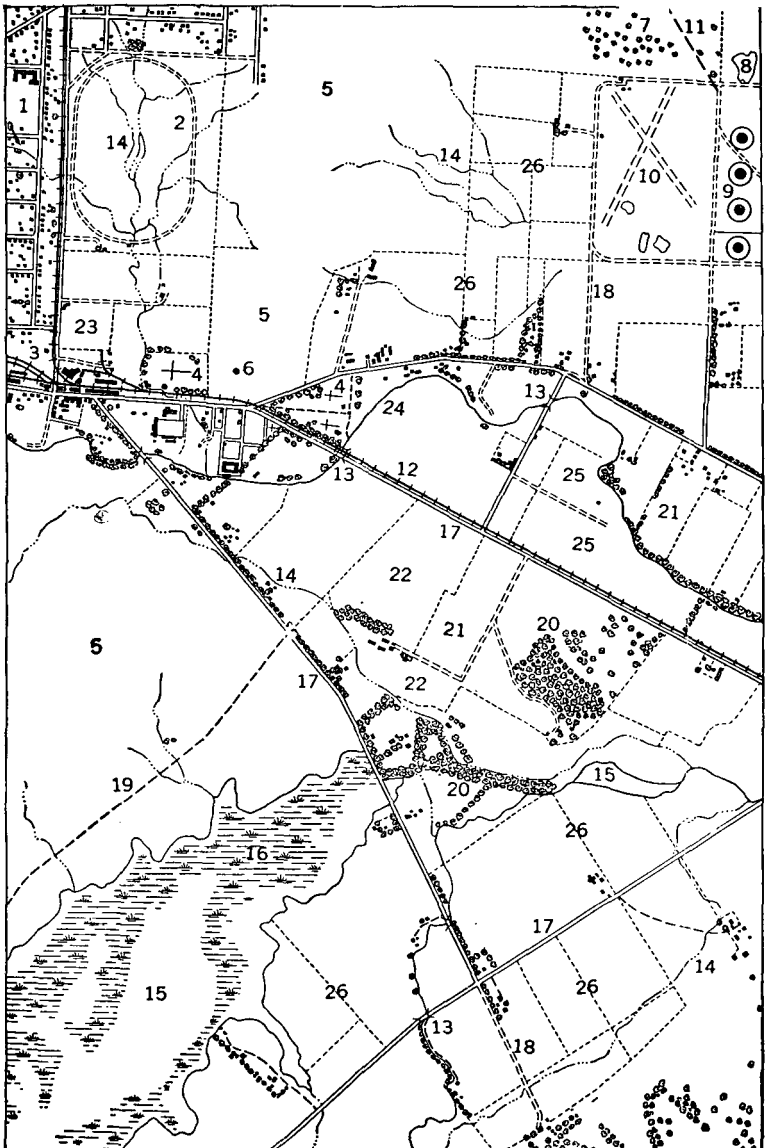
(10) Railroads have more gradual curves, are straighter, and darker in appearance than most roads.

(11) Orchard is identified by its shape and by the straight and regular rows of trees. Shadows of equal length show the trees are all of about the same height.

(12) Mud flats along the stream look darker than the water and have lighter spots in them due to pools of water.

(13) Cluster of buildings shows this is a village.

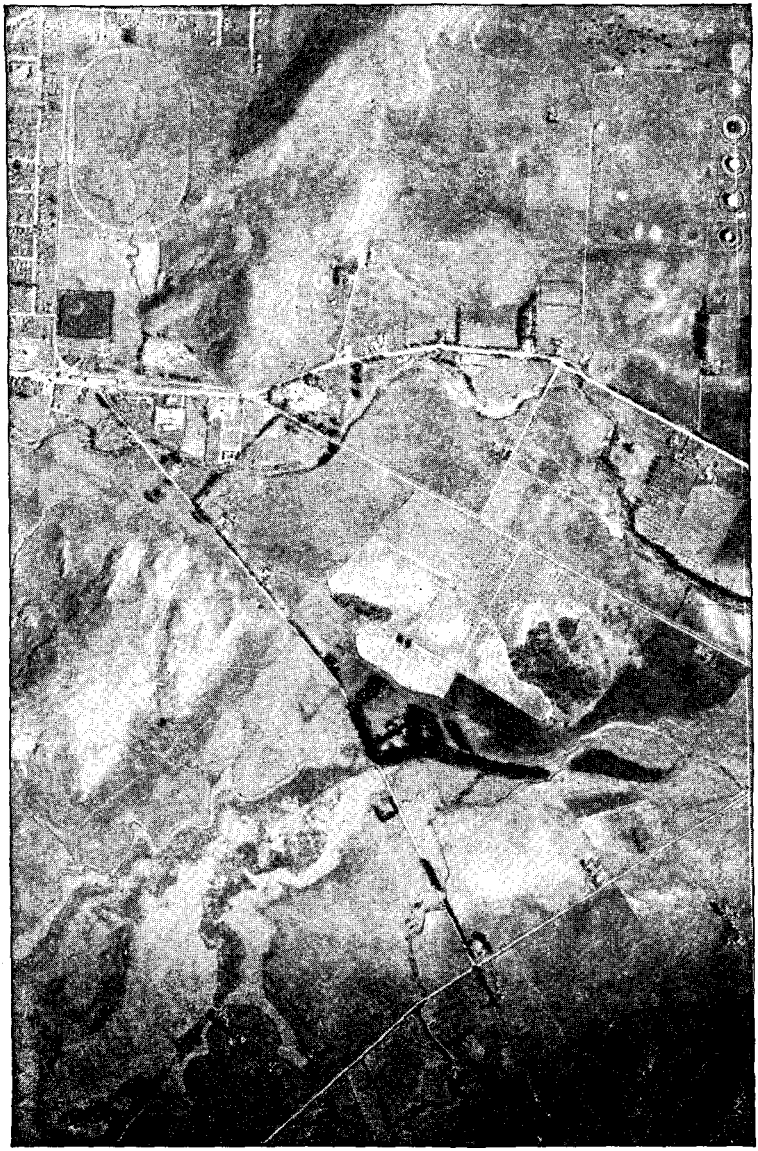
c. A careful study of figure 60 combined with a study of figure 58①, ②, and ③ compared with the map (fig. 1, back of manual) should make the student reasonably proficient in interpreting aerial photographs. It should be remembered that the pictorial effect of aerial photographs is influenced by shadow. In order that this effect will aid rather than hinder the student, he should place the photograph on a table between himself and a lamp, window, or other source of light, shifting it to avoid the glare from its surface and so that shadows on the photograph fall toward him. In this position



1. City; 2. Race track of fair grounds; 3. Railroad yards; 4. Cemetery; 5. Topography with low brush on hillside; 6. Concrete water tank; 7. Scattered wood; 8. Pond; 9. Oil tanks; 10. Airport with runways; 11. Oil pipe line; 12. Railroad; 13. Bridges; 14. Intermittent drainage; 15. Lake; 16. Marshes; 17. First class roads; 18. Secondary roads; 19. Trail; 20. Woods; 21. Orchards; 22. Vineyards; 23. Baseball park; 24. Streams; 25. Pasture; 26. Cultivated fields.

① Vertical aerial photograph.

FIGURE 60.—Interpretation of photographic detail.



② Map of area shown on photograph.

FIGURE 60.—Interpretation of photographic detail—Continued.

objects will have their normal appearance. If the photograph is reversed, that is, placed so that the shadows fall away from the student, actual hollows may appear as hills and trees as holes in the ground.

■ 43. ORIENTATION.—*a. With map.*—(1) When the photograph is used in conjunction with a map it should be oriented with the map. Maps are printed with the north of the map at the top and all lettering, grids, etc., are added on that basis. However, no attempt is made to take photographs to fit this scheme. Photographs may be received without any lettering or direction arrow for orientation. Consequently it may be necessary to study the photograph and identify objects to use in orienting it. When objects shown on the map are found on the photograph it is a simple matter to orient the photograph with respect to the map. Road systems and streams are useful for this purpose. A magnetic north line should then be drawn on the photograph parallel to that on the map.

(2) Another method of drawing the magnetic north line on a photograph is to select two points on the photo that can also be easily identified on the map. The points should be fairly far apart, and the line joining them should pass close to the center of the photograph (points A and B, fig. 58①). Measure on map azimuth of line joining these points. Convert this azimuth to magnetic azimuth. In figure 1 (back of manual) magnetic azimuth of the line A to B is 328°30′. Lay protractor on the photograph (fig. 61) with center of protractor at A and line AB cutting the 328°30′ reading. The base line of the protractor is now lying on magnetic north and south line with north toward the 360° reading. A line with N arrow is drawn parallel to this where desired on the photograph. Further details of this process are given in FM 21–26.

b. With ground.—A photograph may be oriented with the ground by placing some well-defined line as a road on the photograph parallel with the same line visible on the ground. This is similar to the orientation of the map described in paragraph 34b. The same method is used in locating

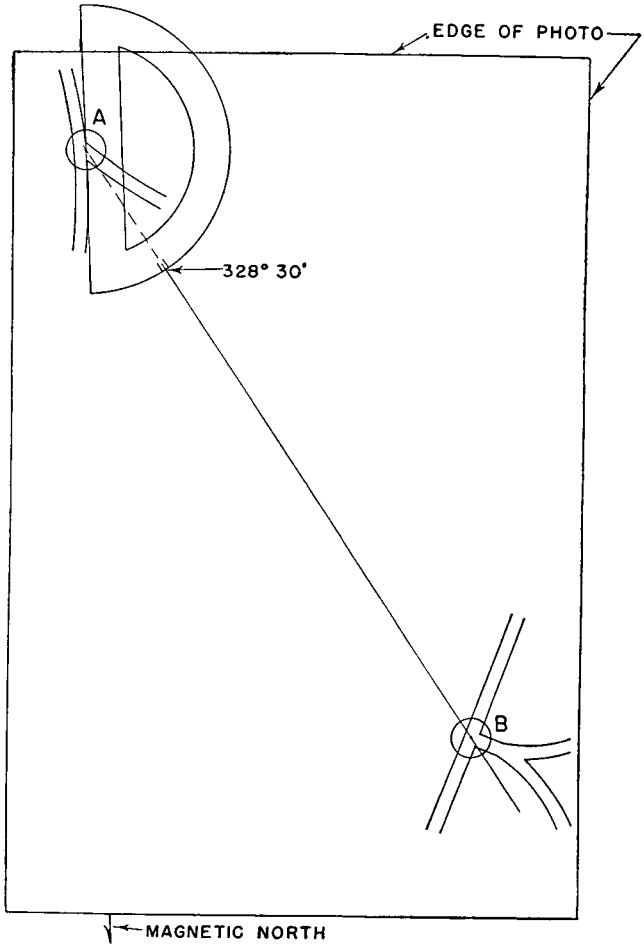


FIGURE 61.—Determining magnetic north on a photograph.

observer's position on a photograph as is used on a map (see par. 35).

c. By shadow.—There may be times when an observer in the field finds it impossible to orient a vertical aerial photograph by either of the above two methods. A third method of rough orientation by use of shadows can be used. In the northern hemisphere shadows fall to the northwest in the morning and to the northeast in the afternoon. Assume the photograph is taken between the usual hours for aerial photography, that is, 10:00 A.M. to 2:00 P.M. The photograph is laid on the ground with the shadows pointing slightly west of north if the photograph was taken in the morning or slightly east of north if taken in the afternoon. The photograph is then approximately oriented. If the exposure is before 10:00 A.M. or after 2:00 P.M., the photograph must be turned west or east of north a correspondingly greater distance.

■ 44. ATLAS GRID.—Because of variations in scale, other inaccuracies, and difficulty of locating grid lines, the military grid is not used on photographs or uncontroled photomaps. The atlas grid is used instead with grid lines always 1.8 inches apart regardless of the scale. With this interval, on a 1:20,000 photograph the grid lines are about 1,000 yards apart. The lines are numbered from the bottom up, and lettered from left to right. Starting at the left edge, the first line is A, the second B, etc. Starting at the bottom the first line is 1, second 2, etc. Therefore, the origin of coordinates at the lower left-hand corner of the photograph is (A.0–1.0) (fig. 62). Points can be located accurately by decimals of the grid interval. For instance, the decimal coordinates of point P would be written (C.5–4.2).

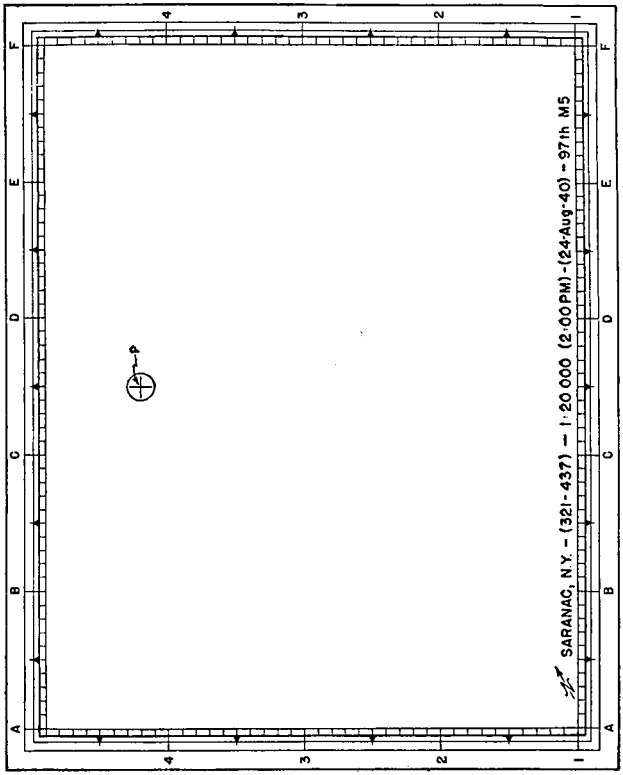

FIGURE 62.—Atlas grid and marginal data.

■ 45. SCALE.—Customarily photographs intended to be used as substitutes for maps will be marked as shown in paragraph 39c. However, they may be received without complete information as, for example, with the scale omitted. In this case the scale must be determined by some other method.

a. By focal length and altitude.—In certain instances, the focal length and altitude at exposure may be shown. This information would appear in the marginal data as follows: (12''-20,000'). This means that the picture was taken with

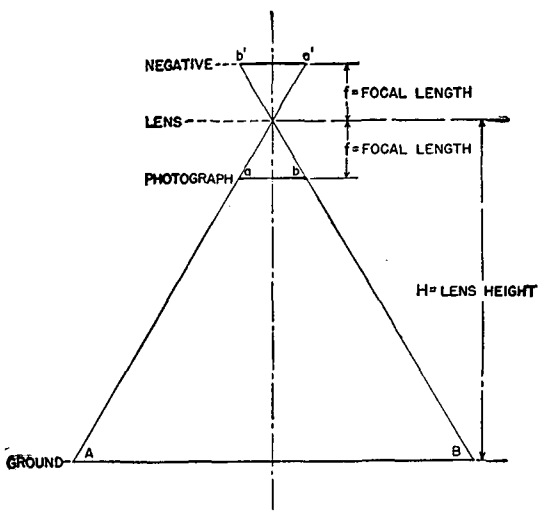

FIGURE 63.—Diagram showing relation of scale, focal length, and lens height.

a camera focal length of which was 12 inches and was 20,000 feet above the ground at time of exposure. By inspection of figure 63 it may be seen that there is a direct relation between focal length of the camera, height of the plane, ground distance AB and corresponding distance ab on the photograph or

$$\frac{f}{H} = \frac{ab}{AB} = RF.$$

If the focal length is 1 foot (12 inches) and the altitude of the plane is 20,000 feet, then the scale of the photograph will be $\frac{1}{20,000}$ or RF=1:20,000. If the focal length had been 6 inches, then the scale would have been $\frac{6/12}{20,000}=\frac{1/2}{20,000}=\frac{1}{40,000}$ or RF=1:40,000. Hence the general expression or formula is:

$$RF=\frac{\text{focal length in feet}}{\text{height of plane in feet}}$$

In some cases the altitude given is the elevation above sea level, and not the elevation above the ground. If the average ground elevation is much above sea level, allowance must be made for this by reducing the plane's height by the elevation of the ground. For instance, in the example given just above, if the elevation of the ground had been 2,000 feet and the altitude given had been the elevation above sea level, the RF would have been actually $\frac{1/2}{20,000-2,000}=\frac{1}{36,000}$ or 1:36,000 instead of 1:40,000.

b. By comparison with map or ground distance.—The average scale of the photograph may be computed by comparison of the distance between two points on the photograph with corresponding distance between the same points on the ground or on a map. For best results the points chosen should be located on the photograph so that straight lines joining them pass fairly near to the center and well across the face of the photograph. For accurate determination see FM 21–26. If required to find the scale of the photograph in figure 58① by comparison with the map in figure 1 (back of manual), select two points such as A and B, that are easily recognizable both on the photograph and on the map. Measure the distance between them both on the photograph and on the map. In this case the map distance is 5.62 inches which on the ground would be 5.62×20,000=112,400 inches since the scale of the map is 1:20,000. Assume the distance between points A and B on the photograph is 5.0 inches. Since it is known that the distance on the ground is 112,400 inches then the RF of the photo is $\frac{5}{112,400}=\frac{1}{22,480}$ or 1:22,480.

Now suppose it is required to find the scale of the photograph in figure 58③ by comparison with the map in figure 1 (back of manual). Select two points such as C and D that can be easily identified both on the photograph and on the map. Proceed as above and in this case the map distance is 2.09 inches which would be $2.09 \times 20{,}000 = 41{,}800$ inches on the ground. Measure the distance CD on the photograph. Assume it is 5.35 inches. Therefore the RF of the photograph is $\frac{5.35}{41{,}800} = \frac{1}{7{,}813}$ or 1:7,813. Note that in both examples, points were selected so that lines connecting them passed close to the center of the picture and that the points were far apart, practically in opposite corners.

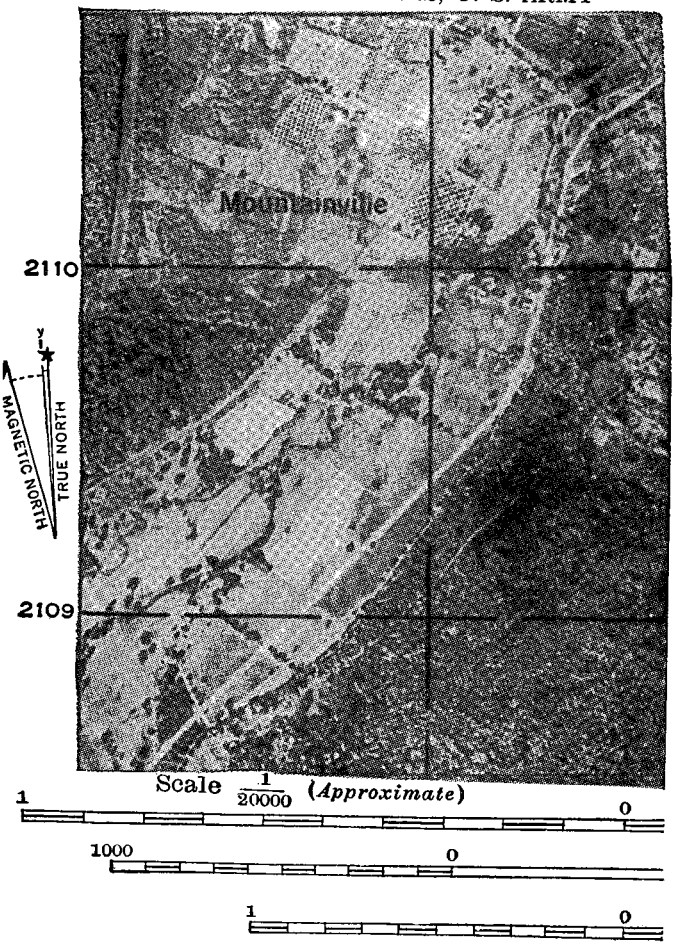
■ 46. MOSAIC.—A mosaic consists of several overlapping vertical photographs joined together. When these photographs are oriented with respect to each other by matching detail in the overlap or along the border, the result is an uncontrolled mosaic which gives a good pictorial effect of the ground but may contain considerable errors in scale and direction. When the several photographs are oriented by means of points along the line of flight and adjusted on previously selected ground points, the result is a controlled mosaic. The controlled mosaic is more accurate and for many purposes is as useful as a map. When several photographs taken from a single airplane flight are joined, the result is a strip mosaic. Strip mosaics are commonly used in the early stages of combat as they are quickly made and give a fairly accurate representation of a more or less extended but narrow section of the terrain.

■ 47. PHOTOMAP.—The term photomap is used as a general term to denote reproductions of vertical aerial photographs, composites, or aerial mosaics. On maps and aerial photographs or photomaps for military usage, roads, railroads, towns, streams, wooded and open areas, and relief are of main interest. Relief is not apparent on any photographs unless there is an overlapping pair that can be seen stereoscopically or unless the photograph is ridge lined and stream lined as described in paragraph 29. Figure 64 is a reproduction of a photomap of about the type which may be expected in the

PHOTO MAP

WAR DEPARTMENT

CORPS OF ENGINEERS, U. S. ARMY



WEST POINT AND VICINITY

FIGURE 64.—Photomap.

field. Although at first glance this photomap appears somewhat indistinct and blurred, those important features referred to above can be seen easily. For example, there is a fairly open valley running from the lower left-hand corner to the upper right-hand corner. There is a stream meandering up the center of this valley. A main highway with several secondary roads runs along its southeastern edge. A railroad, readily identified by means of its long tangents and gradual curves, runs along the northwestern edge of the valley. Several orchards in the vicinity of the town of Mountainville can be picked out. Thus it may be seen that the works of man and changes in wooded and cleared areas are easily seen on a photomap. These are the factors that tend to make a map out of date. The relief as shown on old maps will still be accurate as the ground forms change very slowly. Therefore an up-to-date photomap with any topographic map, whether up to date or not, will give reliable information to the map reader.

■ 48. STEREOVISION.—*a. General.*—The ordinary photograph, as mentioned in paragraph 41, has a flat appearance, which makes it difficult to distinguish between hills and valleys. If two overlapping photographs, known as a stereopair, are viewed either with the naked eyes or with some type of stereoscopic instrument, the effect of depth or relief will be seen and ability had to recognize the actual ground forms. This type of study gives valuable training in understanding and reading both single vertical photographs and photomaps. Consequently, all military personnel should learn and practice stereovision. There are several methods that will assist in acquiring this ability and each individual should experiment until he finds the method that gives him the best results. This ability comes very quickly to most; others will have to use patience and perseverance to obtain it. Experience with large groups of men reveals that anyone with good enough eyes to be in the Army can acquire the ability to see stereoscopically. Stereo studies properly done put no strain on the eyes, and some oculists even prescribe similar exercises to strengthen the eyes. However, when using magnifying spectacles, they should be removed from the eyes before looking up from the photographs.

b. Anaglyph.—Beginners in stereo studies often have difficulty in getting the effect of relief by means of aerial photographs. A simple method of illustrating stereovision is by means of the anaglyph. The anaglyph consists of two different photographs of the same area printed on the same sheet but slightly offset. One is printed in red and the other in blue or green. Relief can be seen when this anaglyph is viewed through a pair of colored spectacles. If the spectacles are reversed or the print is turned upside down, the relief is reversed and ridges will appear as valleys and valleys as ridges. The anaglyph has no practical military value and is used as a quick aid to beginners to illustrate the effects to be obtained by practice in stereovision. For an illustration of an anaglyph see TM 5–230.

UNITED STATES
GOVERNMENT PRINTING OFFICE
WASHINGTON : 1941

For sale by the Superintendent of Documents, Washington, D. C.

WAR DEPARTMENT,
WASHINGTON, September 17, 1941.

FM 21–26, Advanced Map and Aerial Photograph Reading, is published for the information and guidance of all concerned.

[A. G. 062.11 (5–15–41).]

BY ORDER OF THE SECRETARY OF WAR:

G. C. MARSHALL,
Chief of Staff.

OFFICIAL:

E. S. ADAMS,
Major General,
The Adjutant General.

DISTRIBUTION:

D (3); B 1, 2, 4, 6, 7, 17 (2); R 1–7, 10, 17 (5); Bn 1 (10), 2–7, 11, 17 (5), 9, 10 (2); C 2, 5–7, 17 (10), 1, 3, 4, 9–11 (5).

(For explanation of symbols see FM 21–6.)

BASIC FIELD MANUAL

ADVANCED MAP AND AERIAL PHOTOGRAPH READING

(This manual supersedes TM 2180–5, September 28, 1938.)

SECTION I

GENERAL

■ 1. PURPOSE.—The purpose of this manual is to provide a text on map and aerial photograph reading for training of military personnel already familiar with basic elements covered by FM 21–25 or who require more detailed instruction than is furnished by FM 21–25.

■ 2. SCOPE.—Sections I to VI, inclusive, cover an exposition of factors and methods employed in map reading. Sections VII to XI, inclusive, provide an extension of these factors and methods into the related field of aerial photograph reading. The large-scale aerial photograph, within its characteristic limitations, is the logical complement of the small-scale map. Knowledge of the characteristics of aerial photographs and proficiency in the basic art of map reading are prerequisites to proficiency in aerial photograph reading.

■ 3. DEFINITION.—A map is a conventional representation of a portion of the surface of the earth as a plane surface. Since a spherical surface cannot be reproduced as a plane with absolute accuracy, the representation is approximate only, with characteristics dependent upon the projection employed.

■ 4. PROJECTION.—*a. Shape of earth.*—Theoretically, the earth is an oblate spheroid in shape; a figure formed by rotating an ellipse around its shorter axis. Because of the continents and islands, the actual surface is slightly irregular. The distance from the center of the earth to a point at sea level on the Equator is 3,963.3 statute miles and the distance from the center of the earth to either of the poles at sea level is 3,950 statute miles. This difference is so slight that the earth may be mentally pictured as a round ball

or sphere which rotates on a line or axis passing through its center. The imaginary intersections of this axis with the surface of the earth are called the North and South Poles. Circles on the earth's surface, cut by imaginary planes passing through the poles, are called meridians of longitude (fig. 1). Circles cut by imaginary planes at right angles to the axis are callel parallels of latitude. The parallel midway between the poles is called the Equator and

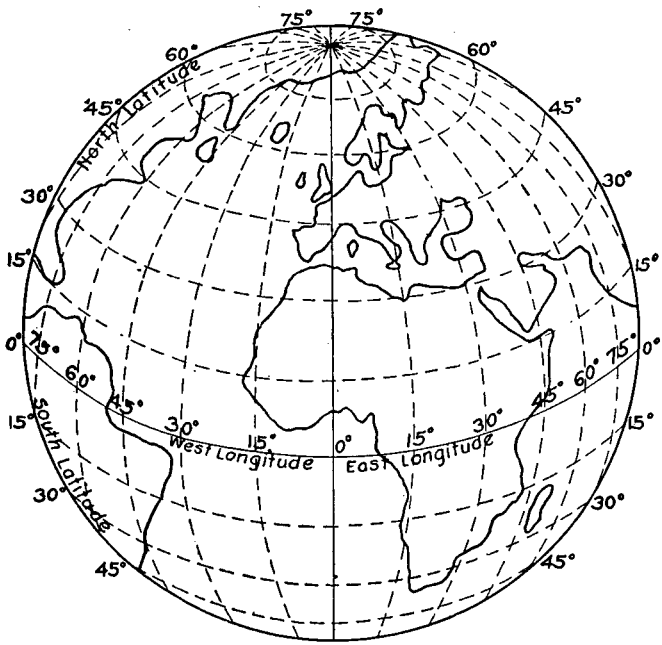

FIGURE 1.—Globe showing meridians and parallels.

divides the earth into the Northern and Southern Hemispheres.

b. Latitude and longitude.—Latitude is expressed by the number of degrees north or south of the Equator, the Equator being 0° and the poles 90°. Points in the Northern Hemisphere have north latitude and in the Southern Hemisphere, south latitude. The meridian of longitude through the

Greenwich Observatory, London, England, has been adopted as 0°. Longitude is measured east or west of the Greenwich meridian to 180°. All points in North and South America have west longitude. (See fig. 1.)

c. Projection.—A map is a representation of a portion of the earth's surface on a plane, and since the earth is a spheroid whose surface is incapable of development as a plane, it is obvious that a map cannot depict a portion of the earth's surface exactly. It is customary in constructing maps to project the portion of the earth's surface under consideration to a surface which is capable of being developed into a plane. A system of developed lines designed for the purpose of constructing a map on a plane surface is called a projection. There have been many kinds of projections devised, all of which may be classified either as equal area, conformal, azimuthal, perspective, or some compromise between these. For further explanation of projection, see TM 5–230.

d. Mercator's projection.—There are several projections based upon a cylinder tangent to the earth along the Equator. That invented by Mercator and known by his name has the latitude scale distorted to equal the stretching in longitude that takes place in developing the sphere upon the cylinder. This distortion is zero at the Equator and infinite at the poles. Due to the rapid distortion when nearing the poles, Arctic land areas such as Greenland are greatly out of proportion. Mercator's projection is used in instrumental navigation, and is the standard projection for hydrographic charts (U. S. Navy), Navy air navigation charts, and Army long distance air navigation charts of small scale.

e. Polyconic projection (fig. 2).—The system adopted for the production of military maps is known as the polyconic projection. On the polyconic projection each parallel of latitude is the developed base of a right cone tangent to the spheroid along that parallel of latitude. Each parallel therefore is a circle whose radius is an element of its tangent cone and whose center is on the axis of the spheroid prolonged. Therefore the radii of no two parallels of latitude, north or south, can be the same. They actually vary between a point at the pole to infinity at the Equator. The result is that parallels of latitude on a polyconic projection are equally spaced along the central meridian of the projection (map),

but this spacing increases rapidly toward the east and west edges. The north-south distortion consequent to this would be prohibitive for military maps on wide projections. In order to avoid this, it is customary to lay out a separate projection for the construction of each standard map sheet, using the central meridian of the map as the central meridian of the projection so that the error or distortion of the projection is limited to the width of a single sheet, in which it is infinitesimal. From this description, it is clear that the characteristics of the polyconic projection are true distances along its parallels of latitude, true distances along its central meridian, and exaggerated distances along all other longitude lines, increasing with the distance toward the east and west edges. Within a projection the size of the United States, the distortion along the Pacific coast would be around 20 percent in a north-south direction.

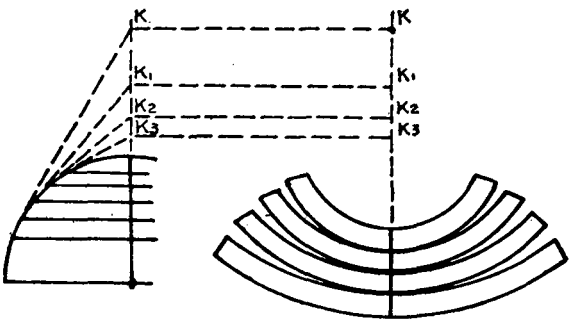

FIGURE 2.—Development of polyconic projection.

■ 5. CLASSIFICATION OF MAPS.—*a. General.*—AR 300–15 prescribes the classification of maps and the specifications for their preparation. Maps used in the theater of operations will consist of those available at the outbreak of hostilities and of those produced thereafter. These maps vary from crude, small-scale planimetric maps to accurate, large-scale topographic maps, and may include various special purpose maps, such as road maps, railroad maps, aeronautical charts, etc. Only in stabilized situations or in a few isolated areas will large-scale maps suitable for tactical operations of small units be found.

b. Types.—Military maps are classified generally according to scale. The general types are—

(1) *Small.*—Maps of small scale varying from 1: 1,000,000 to 1: 7,000,000 are needed for general planning and for strategical studies by the commanders of large units. Various types of general maps are employed for these purposes.

(2) *Intermediate.*—Maps of intermediate scale, normally from 1: 200,000 to 1: 500,000, are required for planning operations, including movements, concentration, and supply of troops. The "Strategic Map of the United States," 1: 500,000, is designed for these uses. Maps of a scale of about 1: 250,000 are particularly applicable to movements of armored forces and as maps of maneuver areas.

(3) *Medium.*—Maps of medium scale, normally from 1: 50,000 to 1: 125,000, are needed for strategical, tactical, and administrative studies by units ranging in size from the corps to the regiment. The United States Geological Survey map, scale 1: 62,500, with wooded areas and road classifications added, has been found suitable for these purposes. This scale is used by the War Department for map production in strategic areas. While not suitable for all purposes, the scale of 1: 62,500 has been found to be the most advantageous for recording topographic detail for future use. During campaign, these maps may be used at this scale or they may be enlarged or reduced according to existing areas.

(4) *Large.*—Maps of large scale, normally not greater than 1: 20,000, are intended for the tactical and technical battle needs of the Field Artillery and of the Infantry. The battle map or map substitute will be furnished for these purposes.

c. Reference.—For a detailed classification of maps by type, see FM 30–20.

■ 6. TRAINING WITH MAPS.—*a. Varied use.*—Any project or operation which involves coordination of movement and employment of groups of men and equipment requires use of a map or map substitute. In peacetime, this may be a sketch indicating a meeting place for a hunting party or an elaborate map of a major railroad system. No organization, with the exception of those involving transportation, utilizes maps more than military forces; and if the variety of types of maps is considered, even the above exception would not apply.

b. Military use.—All arms and services will have occasions to use maps and map substitutes in their respective operations. Modern methods of transportation and warfare demand rapid interpretation of maps by personnel of all units. Lack of time for study in the field necessitates thorough aptitude in map and aerial photograph reading, and the consequent ability to obtain hastily a clear picture of areas represented.

c. Aerial photographs.—Ability to read aerial photographs is required of all military personnel. Usually the nearest thing to a large-scale map in any theater of operations will be aerial photographs in some form. Aerial photographs made under war conditions cannot be expected to depict clearly certain obvious information that is shown in manuals for training in use of aerial photographs. Lack of familiarity with aerial photographs will leave a unit commander with little or no knowledge of valuable information upon which he must make his estimate of the situation.

d. Types of maps used in training.—Equipment used in training should be identical with that used in combat. Nevertheless many troop commanders have been extremely reluctant to use anything except large-scale finished maps in conducting operations. Many junior officers and men become slaves to color maps and contour lines. Initial operations may be with maps of scale 1:200,000 to 1:500,000, or even road maps. The next map available will be some form of photomap, probably a lithographic reproduction of a controlled or uncontrolled mosaic. The large-scale map can be expected only in stabilized situations or for limited areas. The emphasis in training must be placed on such maps, photomaps, or other air photographs as will be available in war. For map restrictions governing training activities, see section IX, FM 30–20.

e. Training in use of maps.—Training in the use of maps and aerial photographs should be planned to include both classroom and field work. The amount of each type of training depends upon the thoroughness contemplated and the size of class. For a small group to receive instruction in the most elementary map and aerial photograph reading, the training should consist of practically all field work. With larger classes and more advanced training, the proportional amount of classroom work increases. In the class-

room, written texts may be used in conjunction with moving pictures (TF–12) or film strips. Film strips with accompanying scripts on map reading (film strip 5–1) and on aerial photography (film strip 5–2) to be shown in 35-mm projectors may be obtained through the corps area or through the Chief Signal Officer, Washington, D. C. FM 21–6 should be consulted to determine what other new publications and aids to training have been prepared or revised in planning any course of instruction.

■ 7. CONVENTIONAL SIGNS.—Conventional signs must be learned just as new words are learned. FM 21–30 or FM 21–25 should be consulted and the conventional signs associated mentally with the objects which they represent.

a. Authorized symbols.—Data are shown on standard and special maps as far as practicable by means of the conventional symbols and type prescribed in FM 21–30. Explanation of the meaning of special symbols should appear in marginal notes.

b. Size of symbols.—In general, symbols resemble the objects which they represent and vary in size with the scale of the map. On small-scale maps, comparatively few objects can be represented and the symbols are reduced to their most elementary form. As the scale is increased, more objects can be represented and more of the symbols can be drawn to the relative shape and size of the object represented.

c. Lettering (type).—The relative size and importance of the feature named are indicated by the size of the type and by the use of capitals and of lower case letters with capital initials. Vertical roman type indicates civil divisions; slant roman type, natural water features; vertical gothic, natural land features; and slant gothic, works of man. Lettering is arranged to be read by the map user from a position at the bottom of the map (south border) or from the right-hand side (east border) since north is usually at the top of the map.

d. Color scheme.—Certain maps may appear in five colors:

(1) Black for the works of man and for the grid.
(2) Brown for contours.
(3) Blue for water and water-covered swamps.
(4) Green for woods and other vegetation.
(5) Red to indicate road information.

■ 8. MARGINAL INFORMATION.—Maps published by the Army and by other Government agencies show along the margin certain information which is of aid in filing the maps, in interpreting them, and in determining their accuracy. The data listed below are usually printed on the margins of all such maps. (See FM 21–30.)

a. Geographic index number of the map and the location in the geographic index of the quadrangle shown on the map sheet. Directions concerning the use of the geographic index system are contained in AR 300–15.

b. Descriptive title, giving the name of the State or States within which the area represented is located and the name of the area or the map quadrangle.

c. Representative fraction of the map and three graphical scales, one in feet or yards, one in meters, and one in miles. (Only one graphical scale is required on maps not intended for lithographing.)

d. True meridian, magnetic meridian (and variation with date and rate of change), and grid meridian.

e. An explanation of any symbol used which is not prescribed in FM 21–30.

f. Contour interval, when contoured.

g. Name of organization which reproduced map.

h. Date of reproduction or revision.

i. Names of organizations executing the surveys and topography upon which the map is based and date of their execution. If the map has been compiled from other maps, source of compilation is also shown.

j. Name of projection used.

k. Horizontal datum. (If no horizontal datum is given, the latitude and longitude of at least one point shown on the map and easily identified on the ground and the method of its determination should be given.)

l. Vertical datum.

m. Zone and system of military grid. Assume continental system if no reference to system is given.

n. If the area represented lies in the overlap of two grid zones, a reference to the grid of the second zone.

o. Designations of the geographic grid lines. These may be ticks only or both ticks and crosses.

p. Designations of military grid lines.

q. Names of adjoining map sheets.

r. An index of adjoining map sheets.

s. Name designation.

NOTE.—Frequently maps are prepared for temporary or local uses and are not intended to be included in any mapping system. Such maps may be encountered by students at service schools or by those pursuing extension courses. Much of the above listed marginal information is not required on such maps and is therefore omitted. This is true of the Gettysburg map used at the Command and General Staff School, which bears a local grid system with its projection based on the town of Gettysburg.

■ 9. GOVERNMENT MAPPING AGENCIES.—In addition to the maps described in paragraph 5, which are published by the War Department and by the United States Geological Survey and which have been adopted as standard for use of the military forces, maps are issued by various Government agencies as follows:

a. Soil survey maps.—These maps are published by the Department of Agriculture on the scale of 1 inch equals 1 mile. They show roads, drainage, towns, and, by symbols and colors, the various classes of soils within the area.

b. Post route maps.—These maps are made by the Post Office Department for the designation of postal routes and are primarily for internal administration in that department.

c. Coast and Geodetic Survey charts.—These charts are intended for the use of navigators on the coast and are published on various scales ranging from 1:5,000 to 1:40,000 for harbor charts and from 1:80,000 to 1:100,000 for coast charts. They show the depth of the water, aids to navigation, and a narrow strip of topography from 1 to 5 miles in width along the shores.

d. Lake survey charts.—These charts are intended for the use of navigators on the Great Lakes and adjacent waters and are published on various scales ranging from 1:5,000 for small harbors to 1:1,200,000 for the general chart of all the lakes. The charts likewise show the depth of the water, aids to navigation, and a narrow strip of topography from 1 to 5 miles in width along the shores.

e. General Land Office maps.—Maps of this bureau are comprised of the following: *Township plots* showing land division and area of tracts; *maps of States* having public land showing land survey lines and United States reservations; *general maps of the United States* showing sources of obtaining land, civil and public land boundaries, and progress of land surveys.

f. International Boundary Commission: United States and Canada.—These maps cover a strip of territory from ½ to 2½ miles in width on each side of the boundary between the United States and Canada, from the Arctic Ocean to Mount St. Elias, from the Pacific Ocean to Lake Superior, and from the head of the St. Lawrence River to the Atlantic Ocean. From Mount St. Elias to Cape Muzon, the boundary maps include practically all the territory between the boundary line and the Pacific Ocean. The scales used are: 1:6,000, 1:12,000, 1:24,000, 1:62,500, and 1:250,000, depending on the locality. The contour intervals range from 5 to 250 feet and the maps are complete in cultural features and relief.

g. United States Forest Service maps.—The United States Forest Service prepares maps of areas included within the national forest boundaries and adjacent thereto. The maps are compiled from all sources, governmental and private, supplemented by United States Forest Service surveys. They are intended primarily for administrative purposes in the United States Forest Service. Besides the topography and culture, they frequently carry detailed classification of vegetation. The publication scales are ¼ inch, ½ inch, and 1 inch to the mile.

SECTION II

DISTANCE

■ 10. LINEAR MEASURE.—*a.* In different countries, various units are used to measure distance. In England the mile is used, in France the kilometer, in Russia the verst, etc. In the United States, the English system of miles is generally used although the metric system is sometimes employed. The American military map reader should therefore be familiar with both English and metric linear measure and be able to express any distance in either unit.

b. The common units of English linear measure are—

12 inches = 1 foot
3 feet = 1 yard
1,760 yards = 1 mile

c. The common units of metric linear measure are—

10 millimeters = 1 centimeter
100 centimeters = 1 meter
1,000 meters = 1 kilometer

d. A distance expressed in English units can be changed into metric units or, if it is expressed in metric units, it can be changed into English units by use of the following relations:

1 meter=almost exactly 39.37 inches or 1.094 yards
1 kilometer=about .62 mile or 1,094 yards

Example 1: A distance on the ground measures 3,300 yards. How many meters does it measure? *Solution:* 3,300÷1.094=3,016 meters (approximately).

Example 2: A distance on the ground measures 2.5 kilometers. How many miles does it measure? *Solution:* 2.5×.62=1.55 miles.

■ 11. SCALES OF MAPS.—Every distance on a map must bear a fixed relation to the corresponding distance on the ground. This fixed relation is called the "scale." Due to the fact that the rise and fall of the ground cannot be shown on the map except by conventional signs (contours and hachures), distances are always measured and written as horizontal distances except when otherwise stated. The vertical distance due to the rise and fall of the ground is called "elevation." For the conventional methods of indicating scales, see FM 21–25.

■ 12. METHODS OF DISTANCE MEASUREMENT.—*a. Graphic scale.*—The measurement of distance on a map by means of the graphic scale is discussed in FM 21–25.

b. By use of map measurer (fig. 3).—The map measurer is an instrument specially designed for quickly measuring distances or lines on a map. It consists of a dial case, handle, and a small wheel or roller. A moving pointer indicates on the dial the distance traveled by the wheel rolling along the line to be measured. Unless the map measurer is graduated to the particular scale of the map being used, it is necessary to convert the units shown on the dial of the instrument to the required units of ground distance. To measure distance with a map measurer, proceed as follows:

(1) Turn the small roller at the side of the dial case opposite the handle to set indicator of map measurer at zero.

(2) Set the roller at one of the given points and, holding

the handle vertical, roll along the line to be measured to the second point.

(3) Under the pointer, read the distance on the divisions on the dial corresponding to the RF of the map.

(4) When there is no scale corresponding to the RF of the map, read the one marked 1: 10,000 and multiply by the denominator of the RF divided by 10,000.

(5) Some dials are divided to read the map distance in inches or centimeters. In this case convert as directed in c (4) and (5) below.

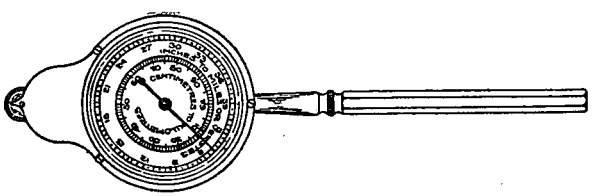

FIGURE 3.—Map measurer.

c. By use of representative fraction and engineer's scale.— The measurement of distance by means of a linear scale necessitates the conversion of the distance (in inches) on the map to the desired units on the ground. On maps of standard scales this is usually done by means of the representative fraction. In order to facilitate the computations which are involved, an engineer's scale should be selected because such a scale is subdivided in accordance with the decimal system. The measurement of the distance between two points on a map is made by proceeding as follows (fig. 4):

(1) Select the edge of the engineer's scale marked 10 (that is, subdivided into tenths of an inch).

(2) Lay the edge on the two points and slide until the zero coincides with one point.

(3) Read the distance on the scale in inches, tenths, and hundredths opposite the other point.

(4) Multiply this distance by the denominator of the representative fraction. This will give the number of inches on the ground between the two points.

(5) To secure the distance in feet, yards, or miles, divide by 12 for feet, 36 for yards, or 63,360 for miles.

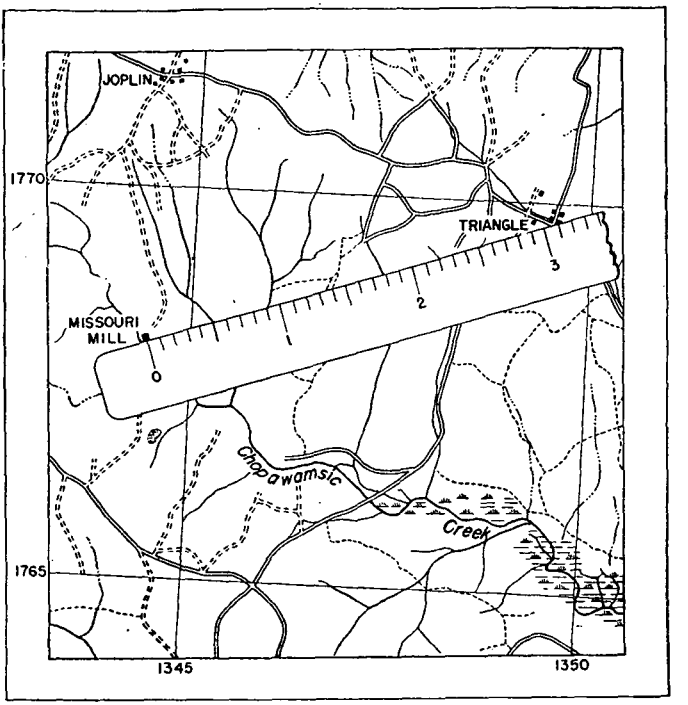

FIGURE 4.—Measurement of distance on a map by means of an engineer's scale.

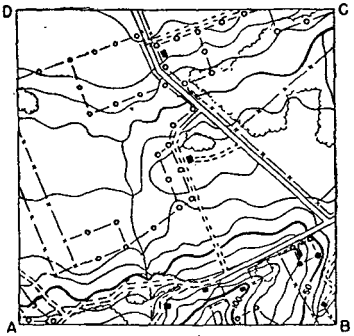
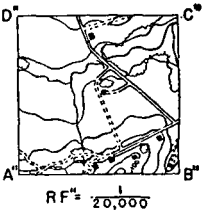
(6) When the denominator of the representative fraction is the same as the number stamped on the middle of an edge of the engineer's scale, or is that number with additional ciphers, the ground distance in inches may be read directly on this edge of the scale, giving careful attention to correct placing of the decimal point.

(7) To measure an irregular line such as a road or stream, divide it into approximately straight sections. Measure each as indicated above. The sum is the required distance.

Example: Figure 4 shows a portion of a map to a scale of 1: 62,500. It is desired to find the distance on the ground between MISSOURI MILL and the road junction at TRIANGLE. Lay the edge of the engineer's scale divided





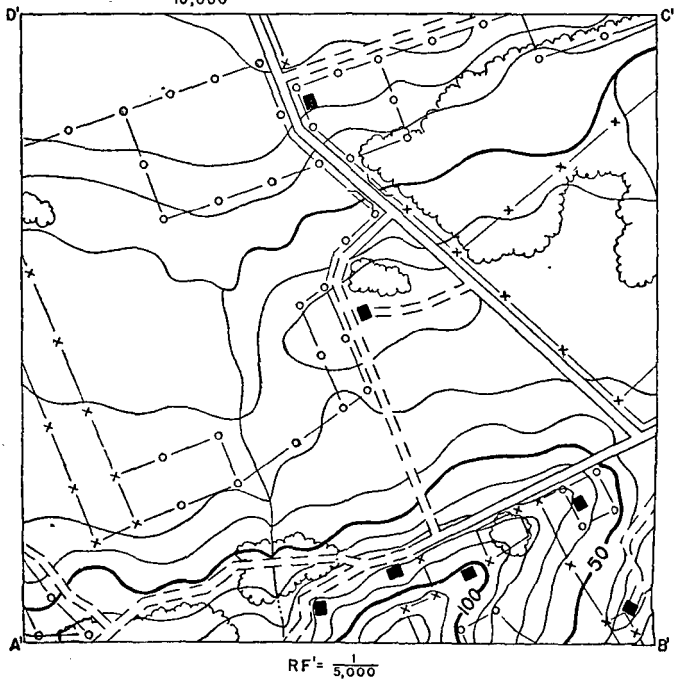


FIGURE 5.—Relation between distances and areas on maps of different scale. (Scales of maps shown above have been reduced in printing.)

into tenths of an inch along the two points. It may be seen that the map distance is 3.07 inches. The distance on the ground is 3.07 times 62,500 or 191,875 inches. This is 15,990 feet or 5,330 yards or 3.03 miles.

■ 13. RELATION BETWEEN DISTANCES AND AREAS ON MAPS OF DIFFERENT SCALE.—Figure 5 shows at a reduced scale an identical area of ground represented on maps of three different scales; that is, 1: 5,000, 1: 10,000, and 1: 20,000. *A*, *B*, *C*, and *D* are points on the ground. *A'B'* on a map of scale 1: 5,000 is just twice as long as *AB* on a map of scale 1: 10,000. The area of the map *A'B'C'D'* at scale 1: 5,000 is just four times the size of the same area at scale 1: 10,000. Conversely, *A''B''* on a map of scale 1: 20,000 is just one-half as long as *AB* on a map of scale 1: 10,000 and the area *A''B''C''D''* is one-fourth the size of *ABCD*. These relationships may be stated as follows:

a. Distances.—Distances on different maps vary directly as the representative fractions of the maps and inversely as the denominators of their respective fractions, thus (fig. 5):

$$\frac{AB}{A'B'}=\frac{RF}{RF'}=\frac{\frac{1}{10{,}000}}{\frac{1}{5{,}000}}=\frac{5{,}000}{10{,}000}=\frac{1}{2}$$

b. Areas.—Areas on different maps vary directly as the squares of the representative fractions of the maps and inversely as the squares of the denominators of their respective fractions, thus (fig. 5):

$$\frac{ABCD}{A'B'C'D'}=\frac{(RF)^2}{(RF')^2}=\frac{\left(\frac{1}{10{,}000}\right)^2}{\left(\frac{1}{5{,}000}\right)^2}=\frac{(5{,}000)^2}{(10{,}000)^2}=\frac{1}{4}$$

■ 14. DETERMINATION OF SCALE OF MAP AND CONSTRUCTION OF GRAPHIC SCALE.—It is important that the user of a map be able to determine the RF of a map when in the field and readily construct a suitable graphic scale for use in the event that the scale data are missing from the map. The procedure is as follows:

a. Determination of scale.—The scale of a map may be determined from known distance on the ground, or from scaled distance on another map of known scale.

(1) *By measurement of distance between two points on ground.*—(*a*) Locate two objects on the ground which can be identified on the map, such as bridges, houses, etc.

(*b*) Estimate, stride, or measure on the ground in some manner, the distance between the selected points, and convert into inches. (The method of measuring should depend on accuracy required, time available, etc.)

(*c*) Measure in inches the distance on the map between the two points selected.

(*d*) Determine the scale from the relation—

$$\text{RF}=\frac{\text{distance on map in inches}}{\text{distance on ground in inches}}$$

This expression, when reduced to a fraction the numerator of which is unity, becomes

$$\text{RF}=\frac{1}{\left(\frac{\text{distance on ground in inches}}{\text{distance on map in inches}}\right)}$$

NOTE.—Distances may be expressed in any unit of measurement provided the same is used for both map and ground distances.

Example: Map distance between two points=3 inches; ground distance between corresponding points=5,208.3 yards.

$$\text{RF}=\frac{1}{\left(\frac{5{,}208.3\times 36 \text{ inches}}{3 \text{ inches}}\right)}=\frac{1}{62{,}500}$$

(2) *By measurement between two points on map of known scale.*—(*a*) Locate two objects on map of known scale which can be identified on the map the scale of which is to be determined.

(*b*) Scale from both maps the distances between the points in the same unit of measurement (inches).

(*c*) Determine the scale of the map by one of the two methods given below:

1. Convert distance on map of known scale to distance on the ground, and solve as in (1) above.
2. Determine scale from the relation—

$$\frac{\text{RF of the map}}{\text{RF of map of known scale}}=\frac{\text{distance on the map}}{\text{distance on the map of known scale}}$$

Example: Distance between two points on the map of unknown scale=8 inches.

Distance between corresponding points on a map of 1:20,000 scale=4 inches.

$$\frac{RF}{\frac{1}{20,000}}=\frac{8}{4}$$

$$RF=\frac{8}{4}\times\frac{1}{20,000}=\frac{1}{20,000\times\left(\frac{4}{8}\right)}=\frac{1}{10,000}$$

It is seen from the above that the denominator of the RF of the map (10,000) is obtained by multiplying the denominator of the RF of the map of known scale (20,000) by the distance measured on that map (4) and dividing by the distance measured on the map the scale of which is sought (8).

b. To construct scale (fig. 6).—(1) Suppose it is desired to construct a graphic scale to read to 1,000 yards for use on a map whose RF has been determined as 1:10,000. The procedure is as follows:

(*a*) 1,000 yards on the ground=36,000 inches. 36,000 inches at scale 1:10,000=$\frac{36,000}{10,000}$=3.6 inches on map, or since 1 inch on the map=10,000 inches on the ground, then 36,000 inches on the ground=$\frac{36,000}{10,000}$=3.6 inches on the map.

(*b*) Lay off the line *ab* (fig. 6)=3.6 inches, using the engineer's scale.

(*c*) Lay off at any acute angle the line *ab'* representing 10 convenient equal divisions of the engineer's scale. Draw the line *bb'* and through each division of the line *ab'* draw lines parallel to *bb'*, to cut the line *ab*, dividing it into 10 equal parts of 100 yards each. Use the left division as the scale extension and further subdivide it in a similar manner into five equal parts of 20 yards each. Mark the graduation as shown in the figure. Show the RF of the scale and the linear unit represented by it.

(2) Another method not so accurate as the above but simpler and quite satisfactory for practical purposes is to compute the length of one 100-yard graduation (or any other suitable division) of the primary scale and then apply that as many times as necessary along a line, as *ab* in figure 6. For example, in the case of the map whose RF was determined as

1:2,769, the length of a 100-yard interval of the scale would be $\frac{3,600}{2,769}$=1.3 inches, approximately. Point off this distance as many times as 100-yard graduations are required for the primary scale, subdividing the left interval as the extension.

■ 15. TIME-DISTANCE SCALES.—In solving tactical problems or in planning military operations on maps, time-distance scales frequently prove time-saving devices of great usefulness. A time-distance scale is a scale whose graduations are

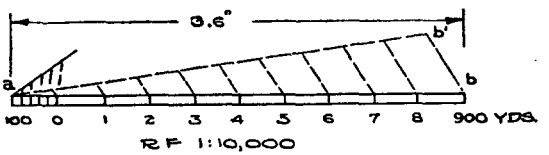

FIGURE 6.—Construction of graphic scale.

time intervals of distance to the scale of the map at a given rate of movement (fig. 7). Suppose that a time-distance scale graduated in hours and minutes of time at a given marching rate, is desired for use on a topographic map 1:62,500. To construct such a scale, the procedure is as follows:

a. (1) In 1 hour, infantry marches 2½ miles or 2½×63,360=158,400 inches.

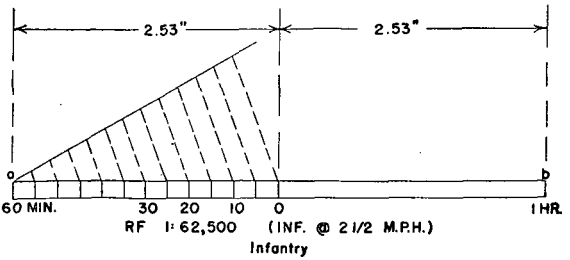
(2) 158,400 inches on the ground=$\frac{158,400}{62,500}$=2.53 inches on a map whose scale is 1:62,500.

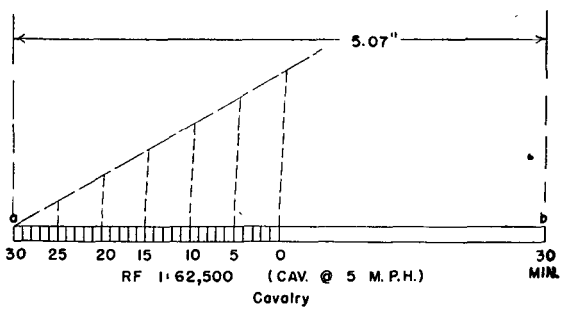
(3) On a suitable strip of paper along a straight line *ab* (fig. 7), lay off as many 1-hour intervals of 2.53 inches each as may be desired in the scale. Subdivide the left interval on the scale extension into 1-minute, 5-minute (used in fig. 7), or 10-minute graduations, depending on the least reading desired; mark the graduations appropriately. On the scale, indicate the RF of the map to which the scale applies and the marching rate to which constructed.

b. (1) In 1 hour, cavalry marches 5 miles or 5×63,360=316,800 inches.

(2) 316,800 inches on the ground=$\frac{316,800}{62,500}$=5.07 inches.

The construction of the scale is similar to that described and illustrated in figure 7.





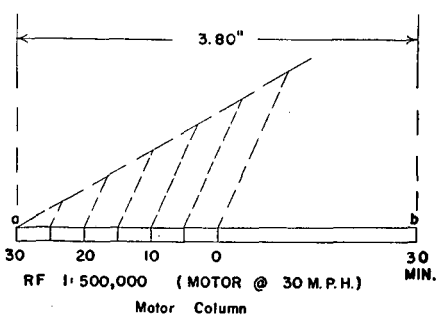


FIGURE 7.—Time-distance scales.

c. (1) In 1 hour, a motor column marches 30 miles or $30 \times 63{,}360 = 1{,}900{,}800$ inches.

(2) 1,900,800 inches on the ground $= \frac{1{,}900{,}800}{62{,}500} = 30.41$ inches on the map.

This shows why operations for units with such rates of march would ordinarily be planned on smaller scale maps. Hence the time-distance scale for a motor column is shown in figure 7 for a 1:500,000 map, making a 1-hour march equal 3.80 inches on the map.

SECTION III

DIRECTION, ORIENTATION, AND LOCATION

■ **16. DIRECTION ANGLES.**—Distance and direction may be used to locate a point or object on the ground or on a map with respect to an occupied or known point. The distance may be measured, paced, or estimated, depending upon the required degree of accuracy. For military purposes direction is always expressed in terms of an angle from some fixed or easily established base direction line.

■ **17. UNITS OF ANGULAR MEASUREMENT.**—The value of an angle may be expressed in degrees, minutes, and seconds; or in mils.

a. Degrees, minutes, and seconds.

A circle $= 360°$
$1° = 60$ minutes.
1 minute $= 60$ seconds.

b. Mils.—A mil is the angle subtended by an arc of 1 unit on a radius of 1,000 units or, in other words, an angle the tangent of which is approximately 1/1,000. The arbitrary value of the mil adopted by the United States Army is 1/6,400 of a circle.

c. Conversion factors.

$1° = 17.8$ mils approximately.
1 mil $= 0.056°$ approximately.
$= 3$ minutes 22.2 seconds.
$= 0.056 \times$ mils.
Mils $= 17.8 \times$ degrees.

■ **18. BASE DIRECTIONS.**—The characteristics of the three base directions are given in table I.

TABLE I.—*Characteristics of base directions*

Designation	Base	Departure from true north	Variations	When used
True north	True meridian	No departure	No variation	In conjunction with geographic map and for permanent records. NOTE.—All directions are assumed based on true north unless otherwise stated.
Magnetic north	Magnetic meridian	Termed magnetic declination and varies in the United States from 25° east in Washington State to 22° west in Maine.	Annual change has been as much as 6 minutes in some localities.	In conjunction with the magnetic compass in the field.
Grid north	True center meridian of the zone of the grid.	Termed gisement and increases to a maximum of approximately 3° at the edge of the grid zone.	No variation	In conjunction with maps on which the military grid is printed.

■ 19. DECLINATION.—Declination is the difference in direction between true north and either magnetic north or grid north. Hence there are two declinations, magnetic declination and grid declination or gisement.

a. Magnetic.—Due to the difference in position between the true and magnetic poles and the inequality of magnetic distribution throughout the earth, there will always be, except in very limited localities, an angle between true north and magnetic north. This angle is called the magnetic declination. When the needle points east of true north, the

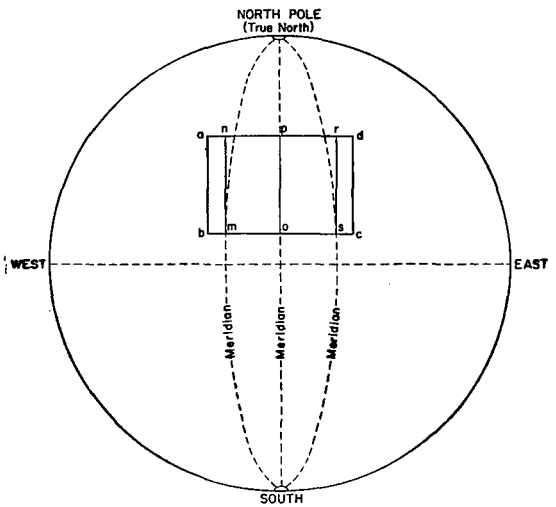

FIGURE 8.—Diagram illustrating reason for grid declination.

magnetic declination is east; when west of true north, the magnetic declination is west. Lines joining points on the surface of the earth where magnetic north and true north are the same direction so that there is no magnetic declination are called agonic lines.

Lines joining points having the same declination are called isogonic lines. The magnetic declination in the United States varies from 25° east in the State of Washington to 22° west in Maine. Isogonic lines run across the United States in a general north and south direction but are very irregular, in some instances doubling back on themselves

(fig. 9). The magnetic declination at any one locality is subject to change, the amount of which can be predicted from past records. This change in some localities in the United States is as much as 4 minutes annually. Magnetic declination and annual magnetic change are shown on maps of the United States published every 5 years by the Coast and Geodetic Survey. Every standard map should show in diagrammatic form the average relation of magnetic and true north for the area of the sheet at a stated date; also the annual magnetic change and whether increasing or decreasing.

b. Grid.—Grid declination is the fixed difference in direction between true north and grid north. Because of the fact that the meridians converge to meet at the pole while all the north-south grid lines (*Y* lines) of the same grid zone are parallel to one another (see par. 34 for an explanation of the military grid system), there is a deviation between true north and grid north except along the central meridian of the grid zone. This deviation is called grid declination or gisement and reaches a maximum of 3° at the edge of the grid zone. It is illustrated in figure 8 which shows a sketch of the projection of the earth with *abcd* representing the area of a map on which the line *op* is the projection of the central meridian of the grid zone. The north-south grid lines are straight lines parallel to *op*. The projections of all meridians other than *op* are curved converging lines which deviate in direction from the direction of the north-south grid lines. This deviation is designated as west grid declination for all points west of the central meridian, as at point *m*, and as east grid declination for all points east of the central meridian, as at point *s*. The declination is determined by finding the angle that the *Y*-grid line makes with true north at the point in question. Although the grid declination varies at different points on a map, this variation on the tactical map is so slight that the average grid declination for the area may be used as the actual grid declination at any point on the map sheet without introducing an appreciable error. Every standard map should show in diagrammatic form the average grid declination for the area represented by the map.

FIGURE 9.—Lines of equal magnetic declination and of equal annual change in United States for 1935.
(For figure see back of manual.)

■ 20. DIRECTION OF ANGULAR MEASUREMENTS.—The characteristics of the methods used to express the direction of angular measurements are given in the following table:

TABLE II.—*Characteristics of methods of expressing directions of angular measurements*

Designation	Units of angular measurement used	Base direction	Direction of measurement
Azimuths	Degrees or mils	True, magnetic, or grid north, unless otherwise stated (south may be used).	Clockwise.
Bearings	Degrees	True or magnetic north and south; whichever used is designated.	Direction which gives smallest arc (must not exceed 90°) is used and is designated.

For military purpose, directions should normally be expressed as azimuths measured from true, magnetic, or grid north.

■ 21. RELATIONSHIP BETWEEN TRUE, MAGNETIC, AND GRID AZIMUTHS AND BEARINGS.—This relationship is shown in figure 10.

Example:

Line *BA:*

Azimuth	60°.
Magnetic azimuth	66°40′.
Grid azimuth	57°35′.
Bearing	N. 60° E.
Magnetic bearing	N. 66°40′ E.
Back azimuth	240°.

Line *AB:*

Azimuth	240°.
Magnetic azimuth	246°40′.
Grid azimuth	237°35′.
Bearing	S. 60° W.
Magnetic bearing	S. 66°40′ W.
Back azimuth	60°.

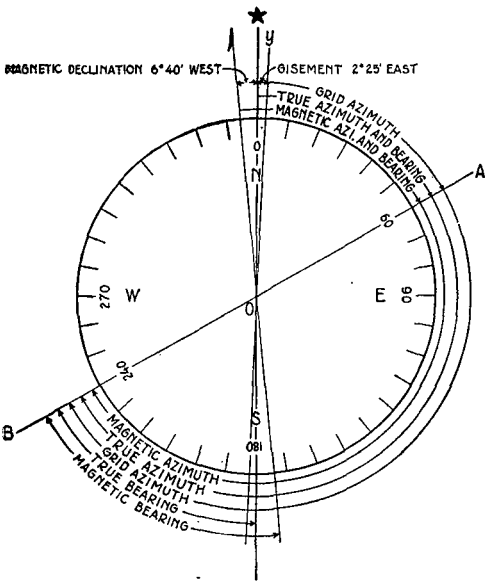

FIGURE 10.—Relationship between true, magnetic, and grid azimuths and bearings.

■ 22. MAGNETIC COMPASS.—There are three types of magnetic compasses used by the Army, varying chiefly in scales and sights. Below is a brief description of each; for a more complete description of the compass and its use, see FM 21–25.

a. Watch compass.—The watch compass has a movable needle, a fixed dial graduated in bearings, and has no sighting device.

b. Prismatic compass.—The prismatic compass has a circular magnetic floating dial, prismatic eyepiece, and a north point painted in luminous paint in the case. One of the two dial graduations is read through the prism and the other is read direct. Each scale is graduated from 0° to 360°. The forward sight is a hair line on the glass in the top of the case.

c. Lensatic compass.—The lensatic compass functions in much the same manner as the prismatic compass. It contains a magnifying lens fixed in a hinged eyepiece. The face has two scales, one graduated in degrees, the other in mils.

■ 23. LOCAL MAGNETIC ATTRACTION.—In addition to the compass variation caused by magnetic declination, the magnetic compass is affected by the presence of iron and electrical fields of magnetism. Consequently, great care should be taken not to approach such local magnetic attraction within a distance which will cause the magnetized compass needle to deviate while making observations to determine direction. The rifle, pistol, and helmet must be laid aside when reading the compass. The following are the minimum safe distances for visible masses of iron and electrical fields of magnetism:

	Yards
High tension power lines	150
Heavy gun	60
Field gun and telegraph wires	40
Barbed wire	10

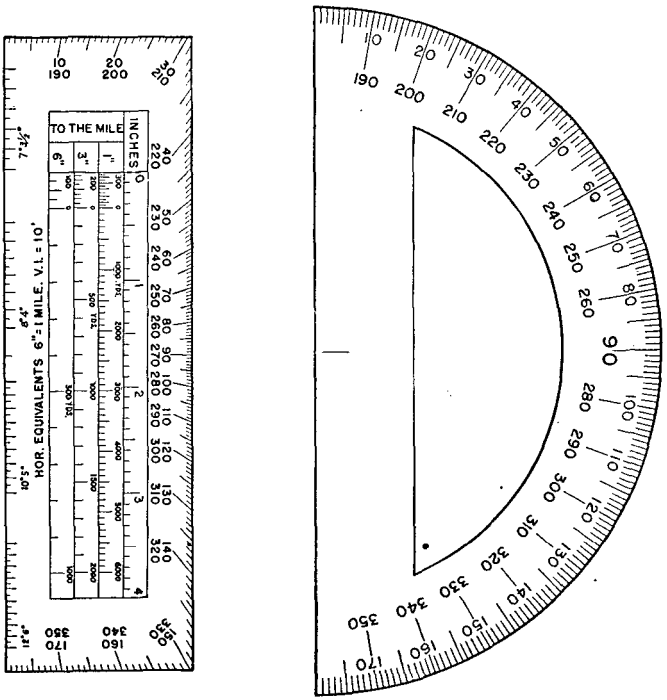
■ 24. PROTRACTOR.—*a. Relationship between semicircular and rectangular protractors.*—In figure 11 it will be noted on each protractor that two scales are shown, one reading from 0° to 180° and the other from 180° to 360°. With both scales, each protractor can be used to read the full circle in degrees. Inasmuch as both the semicircular and the rectangular protractors are used in the same manner, the method of using the less familiar type only is given.

b. Use of rectangular protractor (fig. 12).—Assuming the *Y*-grid lines are available on the map and the angle which magnetic north makes with grid north is shown on the map margin to be the sum of the magnetic declination 6°21′ and gisement 2°35′ or 8°56′, to lay off the magnetic azimuth of a line *AB* the procedure is as follows:

(1) Join the points *A* and *B* by a fine, lightly drawn line and prolong until it crosses the nearest *Y*-grid line and extends beyond the edges of the protractor.

(2) By inspection, the azimuth is seen to be less than 180° and therefore should be measured on the outside or lesser azimuth circle (0° to 180°) of the protractor with the protractor placed on the east side of the direction line.

(3) Place the protractor along the intersected grid line 65 and shift it until the index coincides with the point where *AB* prolonged crosses the grid line. About this point as a pivot, turn off an angle of 8°56′ (or 9° in practice, since the difference is unmeasurable) counterclockwise. The index



① Rectangular. ② Semicircular.

FIGURE 11.—Military protractors.

edge of the protractor is now on the magnetic meridian. The value of the azimuth angle sought is read 61°00′ at the point on the outside azimuth "circle," where the line *AB* prolonged cuts the edge of the protractor.

(4) Suppose, however, the problem is to measure the magnetic azimuth of the line *BA*, which is the back azimuth of the line *AB* and differs from it by 180°. By inspection this is seen to be greater than 180°, requiring use of the inner "circle" of graduations (180° to 360°) with the position of the protractor on the opposite side of the grid line. The procedure is similar to that just described except the protractor is placed on the west side of the 65 grid line, the angle 8°56′ is turned off counterclockwise from the south end of the pro-

tractor, and the angle of 241°0′ is read on the inner "circle" where *BA* prolonged crossed the graduated edge of the protractor.

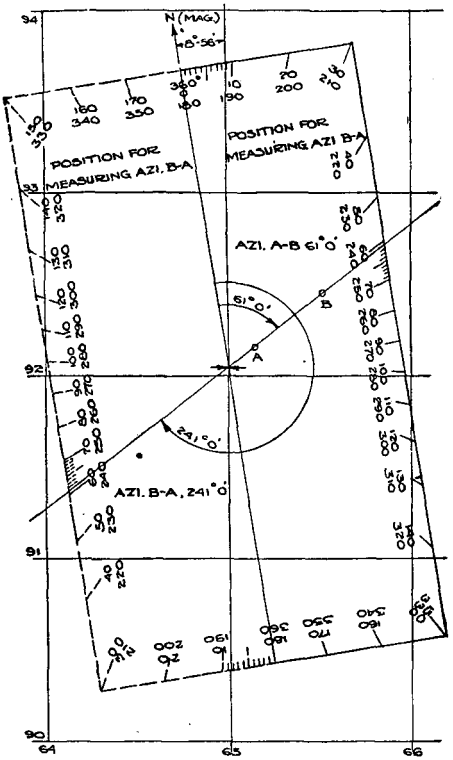


FIGURE 12.—Use of rectangular protractor.

■ 25. DETERMINATION OF DIRECTION BY FIELD EXPEDIENTS.—*a. By aid of watch and sun* (fig. 13).—North can be determined with an error of less than 8° if the sun is visible and a watch showing approximately the correct sun time is available. Point the hour hand, watch held face up, at the sun. This is facilitated by casting the shadow of a vertical pencil across the face of the watch and by then bringing the hour hand into this shadow. A line drawn from the center of the dial

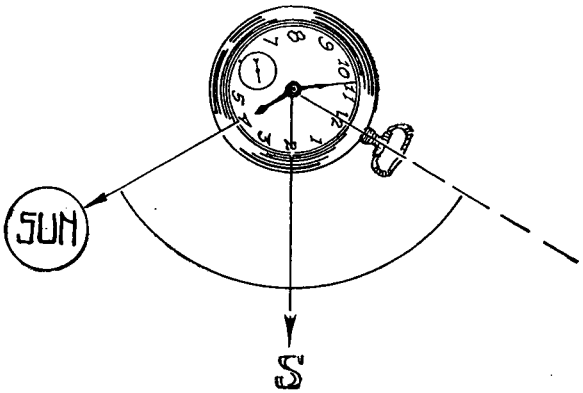

FIGURE 13.—Determination of north by watch and sun.

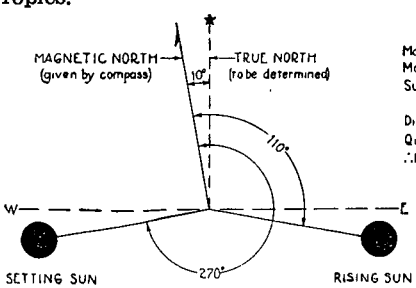
to a point halfway on the smaller arc between the hour hand and the 12 of the watch will point south. In the Southern Hemisphere the watch must be held face down and this line will point north. This method is difficult to use when the sun is very high in the heavens and is of little or no use in the Tropics.



COMPUTATIONS

Mag. azi. of rising sun	110°
Mag. azi. of setting sun	+270°
Sum	380°
	−360°
Difference	20°
Quotient (÷2)	10°

∴Magnetic Declination is 10° West

FIGURE 14.—Determination of north by rising and setting of sun.

b. By rising and setting of celestial body (fig. 14).—Observe the magnetic azimuth of the sun, a planet, or a bright star at rising and setting on the same day or at setting on one day and rising the next. Add these two azimuths together. Take the difference between this sum and 360°. One-half of this difference is the declination of your compass—east, if the sum of the azimuths is less than 360°; west, if it is greater.

In using this method the observations are best taken when the object is just above the true horizon, or at a gradient of zero. This can usually be done if a high point is chosen for observation. If this cannot be done, be careful to take both observations with the object at the same gradient, as determined with a clinometer. This is most important with the sun. Under the least favorable conditions an inequality of 1° in the gradients at the time of observation on the sun may introduce an error of ½° in the result. In using a star, choose one which rises nearly east from the point of observation. If this is done the inequality of a degree in the gradients will be immaterial. Both observations need not be made at the

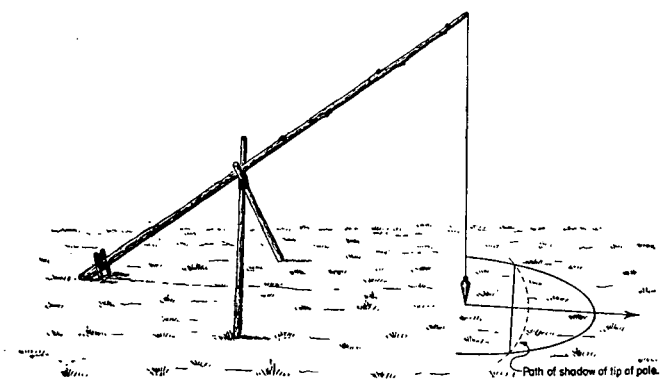


FIGURE 15.—North by sun and plumb line.

same point, but should not be more than 10 miles apart in east and west or north and south directions.

c. By aid of sun and plumb line (fig. 15).—On a level piece of ground, lean a pole toward the north and rest it in a crotch made by two sticks, as shown. Suspend a weight from the end of the pole so that it nearly touches the ground; then, about an hour before noon, attach a string to a peg driven directly under the weight and, with a sharpened stick attached to the other end of the string, describe an arc with a radius equal to the distance from the peg to the shadow of the tip of the pole. Drive a peg on the arc where the shadow of the tip of the pole rested. About an hour after noon, watch the shadow of the tip as it approaches the east-

ern side of the arc and drive another peg where it crosses. By means of a tape or string, find the middle point of the straight line joining the last two pegs mentioned. A straight line joining this middle point and the peg under the weight will, for all practical purposes, be true north.

d. By means of North Star (Polaris).—Ursa Major (Big Dipper) shown in the upper portion of figure 16 is the easiest constellation to distinguish and provides the best

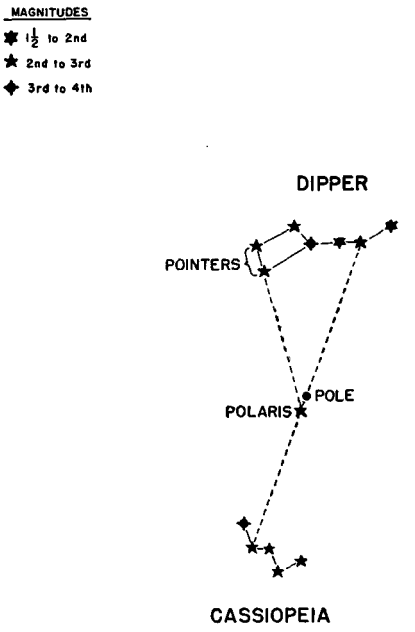

FIGURE 16.—Determination of north by North Star.

means for locating the North Star. The two "pointers," or the stars forming the lip of the dipper, point to the North Star (Polaris) at all times as the Dipper appears to circle the pole. On the opposite side of Polaris and at about the same distance from it is the constellation of Cassiopeia. Its form is that of the letter "W." The great importance which attaches to the North Star is that it is never more than 2° away from the point where the axis of the earth, if extended,

would pierce the heavens. It therefore appears to the eye to be always in the same place. An observation of the North Star to determine true north, when the Dipper and Cassiopeia are above and below the North Star, will give the declination of the compass to within the least reading of the compass.

■ 26. ORIENTATION.—*a. Definition.*—A map is oriented when, in a horizontal position, its north point points north and all lines of the map are parallel to the corresponding lines

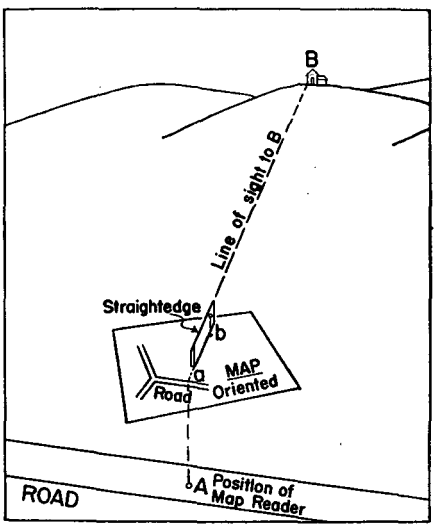

FIGURE 17.—Location of one's position on map by resection when along road (graphic method).

of the ground. A map reader is oriented when he knows his position on an oriented map and the cardinal directions on the ground. A map will be of small use in the field unless its possessor can orient himself readily. It follows that ready command of the simpler methods of practical orientation is of prime importance to the student of map reading.

b. Methods of orientation.—Primary methods of orientation by inspection, with a compass, and by sighting on a distant point (given in FM 21–25) should be known to ad-

vanced students and are not repeated here. Several methods of orientation by resection are given below.

c. Location of one's position along road or similar feature by resection.—The position may be determined graphically or may be plotted by means of a protractor after a compass has been used to give direction. The first method is the speedier and is most commonly employed when the determination of position is undertaken in the field.

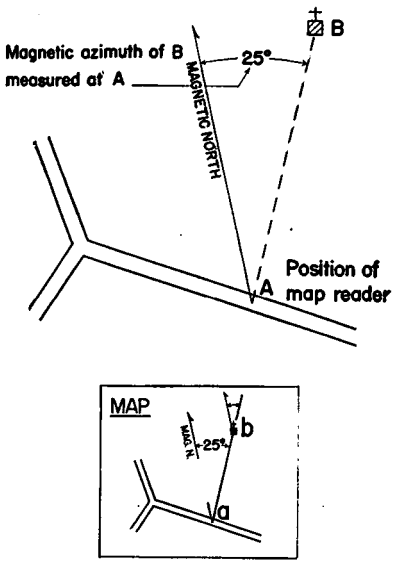

FIGURE 18.—Location of one's position on map by resection when along road, using compass and protractor.

(1) *Graphic method* (fig. 17).—Proceed as follows:

(*a*) Identify a convenient visible object *B* on the ground which appears on the map at *b*.

(*b*) Rest the map in a horizontal position on some nearby convenient support, such as a fence post, stone, or fold in the terrain, from which *B* is visible, and set a pin in the map at *b*.

(*c*) Orient the map.

(*d*) Without moving the map, hold a straightedge against the pin at *b* and aline its edge with the object *B* on the terrain.

(*e*) Draw a line through *b* along the straightedge and prolong it to intersection with the road at *a*. This intersection is the point sought.

(2) *By means of compass and protractor* (fig. 18).—Proceed as follows:

(*a*) Identify a convenient visible object *B* on the ground whose position *b* appears on the map.

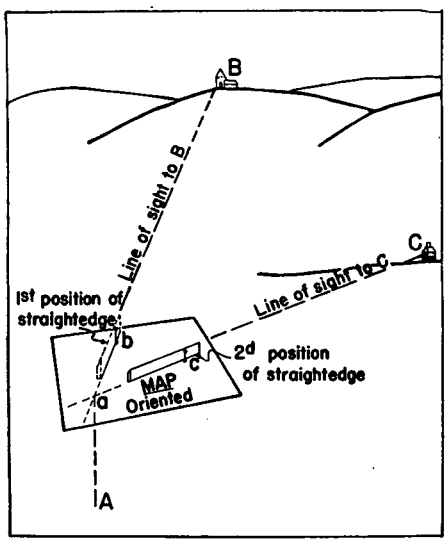

FIGURE 19.—Location of one's position on map by resection from two distant points (graphic method).

(*b*) With the compass, sight *B* and read the magnetic azimuth.

(*c*) On the map with the protractor lay off this azimuth through *b* and prolong the line until it intersects the road at *a*, which is the position sought.

NOTE.—When azimuths are read from observer to a known position, either the azimuth or back azimuth may be used in plotting the direction line through the known position.

d. Location of one's position by resection from two distant points.—This method of locating a position is useful when no well-defined feature, such as a road, is in the vicinity. The position may be determined graphically or may be plotted by means of a protractor after directions have been read by a compass. The first method is speedier and is most commonly employed when the determination of position is undertaken in the field.

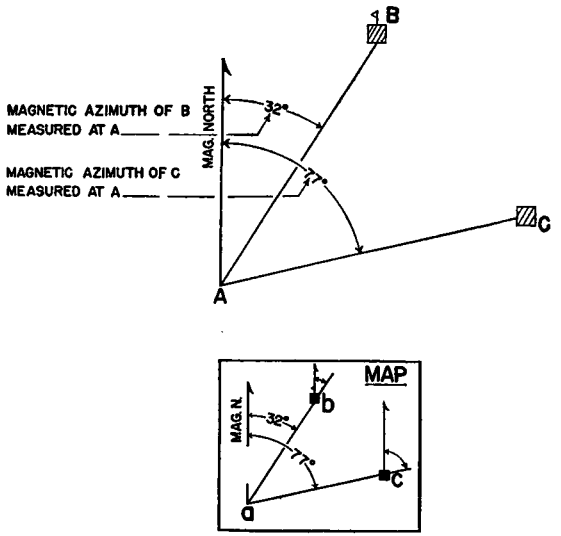

FIGURE 20.—Location of one's position on map by resection from two distant points, using compass and protractor.

(1) *Graphic method* (fig. 19).—Proceed as follows:

(*a*) Select two visible objects on the terrain, as *B* and *C*, whose positions *b* and *c* appear on the map, so situated that lines radiating from observer to objects form an angle of 30° to 150° at the observer.

(*b*) Rest the map in a horizontal position on some nearby convenient support, such as a fence post, stone, or convenient fold in the terrain, from which the objects *B* and *C* on the terrain are visible and set pins through their respective map positions, *b* and *c*.

(*c*) In this position, orient the map.

(*d*) Without moving the map, sight *B* and *C* successively on the terrain along a straightedge held against the pins through the corresponding points *b* and *c*, respectively. Along the straightedge, draw lines through *b* and *c* and prolong these lines to intersection at *a*, which is the point sought.

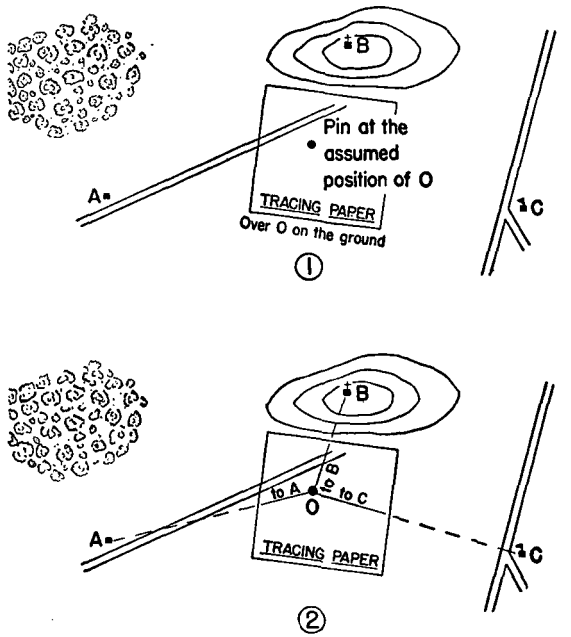

FIGURE 21.—Location of one's position on a map by resection from three distant points (tracing paper method).

(2) *By means of compass and protractor* (fig. 20).—Proceed as follows:

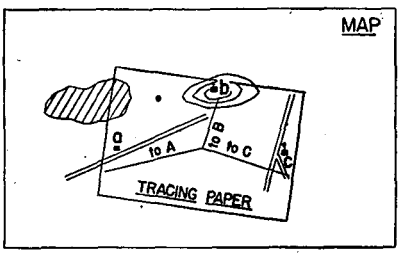
(*a*) Select two visible objects on the terrain, as *B* and *C*, the positions of which, *b* and *c*, can be identified on the map and which are so situated that lines radiating from observer to object make an angle of 30° to 150° at the observer.

(*b*) With the compass sight the objects on the landscape successively, reading the magnetic azimuth to each.

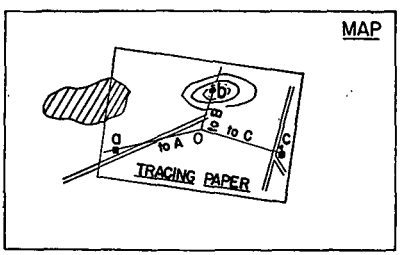
(*c*) Draw magnetic north guide lines through the map position of each object, *b* and *c*, and with the protractor lay off the respective magnetic azimuths.

(*d*) Prolong the azimuth lines through the points *b* and *c* until they intersect.

(*e*) The intersection of these lines at *a* is the map position sought.



③



④

FIGURE 21.—Location of one's position on a map by resection from three distant points (tracing paper method)—Continued.

e. Location of one's position by resection from three distant points (tracing paper method) (fig. 21).—This method is useful on unoriented maps when the observer is without a compass in indefinite terrain of which only distant prominent features are recognizable or when local attraction due to presence of ore bodies or other material renders the magnetic needle useless.

(1) Select three visible objects on the terrain such as *A*, *B*, and *C*, so distributed that radial lines drawn from observer to each point will yield good angles of intersection (about 30° to 150°) at *O*, the position occupied by the observer (fig. 21①).

(2) Place a piece of tracing paper on a flat surface, supported on a convenient fence post, rock, or on the ground,

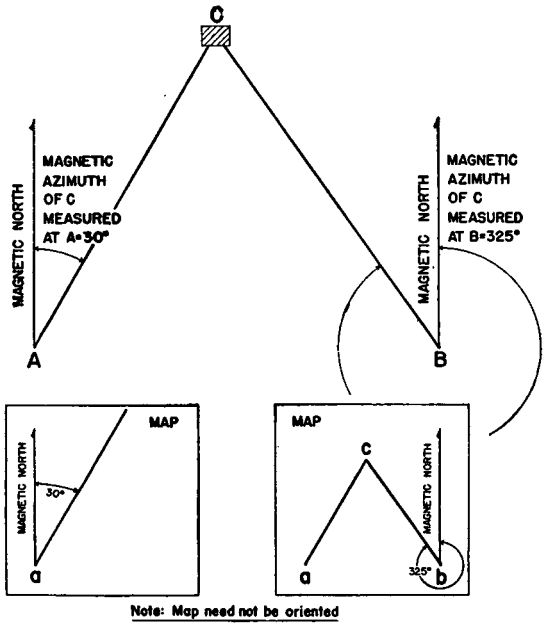


FIGURE 22.—Location on map of distant point by intersection, using compass and protractor.

and set a pin in it at any convenient assumed position of the observer at *O*.

(3) Place any suitable straightedge against the pin, sight along its edge successively to each object, *A*, *B*, and *C*, on the terrain and draw radial lines along the straightedge toward each object (fig. 21②).

(4) Remove the tracing paper and superimpose it over the map (fig. 21③), shifting it about until the three radial

lines pass through the conventional signs *a*, *b*, and *c* on the map which correspond to the three objects sighted on the ground (fig. 21④).

(5) In this position, prick the map through the original pinhole *o* on the tracing. The point thus located on the map is the position of the map reader.

■ 27. LOCATION OF DISTANT POINT BY INTERSECTION.—*a. With compass and protractor.*—It is frequently desirable to locate or post on a map distant or inaccessible objects on the terrain

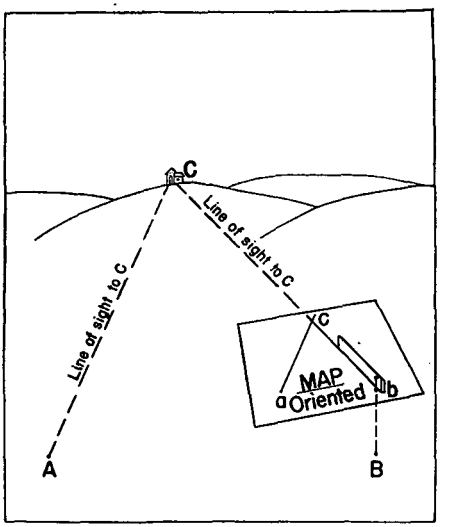

FIGURE 23.—Location on map of distant point by intersection (graphic method).

which do not appear on the map in hand. This may be conveniently done by intersecting lines from two occupied points of known position on the map. Assume that the location of an object *C* shown in figure 22 is desired on a map. In order to locate the position of *C*, one must occupy successively two positions, such as *A* and *B*, from which the object *C* is visible and read the magnetic azimuth of *C* from *A* and *B*, respectively. By aid of a protractor, these azimuths are plotted through the corresponding positions *a* and *b* on the map.

The direction lines prolonged will intersect at *c* on the map, the position sought. Many points may be thus located on the map from two occupied positions.

b. Graphic method (fig. 23).—The observer occupies in succession the positions *A* and *B* on the ground. In each position he rests the map horizontally on some nearby convenient support and sets a pin in the corresponding map positions *a* and *b*, respectively. In each position the map may be oriented with a compass, by inspection, or by alining the positions *a* and *b* on the map with the corresponding objects *A* and *B* on the ground. The last method is the most accurate. At each occupied position a straightedge is placed against the pin in the corresponding position on the oriented map, the object *C*, the position of which is sought, is sighted along the straightedge and a direction line drawn thereto. This results in two such direction lines, one from each occupied position, the intersection of which gives the map position *c* of the object *C*. The results may be checked by a direction line from a third position of the observer.

■ 28. TRAVERSE.—*a.* A series of lines of known distance and direction is called a traverse. An approach route to an assembly area, designated with distances and directions from point to point, would form a traverse.

b. In locating on the terrain objects which do not appear on the map and which cannot be intersected, or in exploring unfamiliar terrain equipped with a compass, the method of traversing is useful. This consists of starting from a known point and following observed compass courses from point to point, measuring distances. These course lines and distances, when plotted to scale on the map, show graphically the course followed and the map location of any desired point on the traverse. Where the distance to the point sought is great and the intervening terrain is rough, it is not practicable to attempt its location by means of a simple straight course. In such cases the traverse would consist of a meander of many straight course lines and angles making changes of direction as influenced by the intervening terrain but ultimately terminating at the point sought. Scouts use this method in registering on a map the route they follow.

SECTION IV

COORDINATES

■ 29. SYSTEMS OF COORDINATES.—*a.* In order to express absolute or relative positions of points, either on a map or on the terrain, one or more of four different systems of coordinates may be selected. Each system has its appropriate use. The names of these systems are as follows:

(1) Polar coordinates.

(2) Rectangular coordinates.

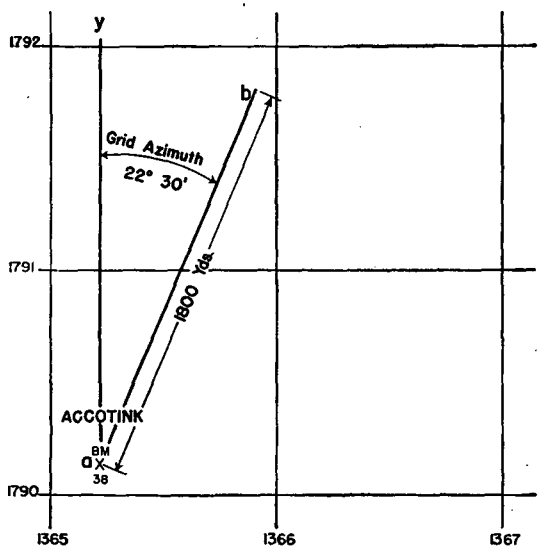

FIGURE 24.—Polar coordinates: BM 38, Accotink (village), distance 1,800 yards, on grid azimuth 22°30'.

(3) Geographic coordinates.

(4) Grid coordinates.

b. Rectangular and polar coordinates are classified as relative coordinates because they are determined by reference to base points (and directions) local to some map and selected by some individual. Thus an indefinite number of polar or rectangular coordinates may be assigned to a single point.

Geographic and grid coordinates are termed absolute coordinates because each is determined by reference to a permanently fixed base point and direction which have been officially adopted for that purpose. Thus only one set of geographic coordinates or, for any grid zone, only one set of grid coordinates can be assigned any point and this set of coordinates is not affected by the selection of map.

■ 30. POLAR COORDINATES.—Polar coordinates are used in designating points located with a compass in the field and in designating positions on maps not equipped with the military grid. They consist of an angle from a known base direction and a distance from a known base position. The base position is the origin of coordinates. It may be a fixed landmark, a survey monument, or any other position easily identified on the map and on the ground. The base direction may be true, magnetic, or grid north or south. The angle may be expressed as azimuth or bearing, the distance in any convenient distance unit. The base position or origin should be fully described.

Examples: Walla Walla quadrangle, BM 1224, on main road 2 miles westerly from Waitsburg, S. 22°45′ W. magnetic (1920) 4.62 miles.

Battle map, Fort Belvoir, 1:20,000 (1935), BM 38, Accotink (village), distance 500 yards N. 30° W. magnetic.

Battle map, Fort Belvoir, 1:20,000 (1935), BM 38, Accotink (village), distance 1,800 yards, on grid azimuth 22°30′. The point so designated is marked *b* in figure 24. The base position, BM 38, is marked *a*, the distance from the base position is the line *ab*, the base direction (grid north) is *ay*, and the angle from the base direction is *yab*.

In dealing locally with many points common to a single map sheet, the sheet reference may be omitted.

a. To plot position of point, polar coordinates of which are given.—(1) Locate on the map the landmark or other base position (origin) given.

(2) Through the base position draw a guide line parallel to the base direction.

(3) With a protractor, point off from the guide line radially about the base position the given angle (azimuth or bearing).

(4) Through the point thus established and the base position (origin) draw a guide line.

(5) Along this guide line from the base position lay off the given distance to scale.

b. To determine polar coordinates of map position with respect to given position and given direction.—(1) Locate on the map the given base position and through it draw a guide line parallel to the base direction.

(2) Draw another guide line through the base position and the point whose polar coordinates are sought.

(3) With the protractor, measure the angle (azimuth or bearing) which the direction line established in (2) above makes with the base direction line established in (1) above.

(4) With a suitable scale at the RF of the map, measure the distance from the base position to the point the coordinates of which are sought.

■ 31. RECTANGULAR COORDINATES.—Rectangular coordinates are used in designating points on ungridded maps without the aid of a protractor. They consist of two distances measured at right angles from a base position. The base position (origin) should be a landmark, survey monument, or other well-established position. The base position, distances, and directions should be fully stated, thus:

Walla Walla quadrangle, NE. cor. T. G. N., R. 36 E., thence due east 811.7 yards, thence due north 409.2 yards.

Battle map, Fort Belvoir, 1:20,000 (1935), BM 38, Accotink (village), 1,500 yards east (magnetic), 1,100 yards north (magnetic. The point so designated is marked *c* in figure 25. The base position, BM 38, is marked *a*, the base direction (magnetic north) is *am*, the direction of the line *ab* (grid east) makes a right angle with the line *am*, and the respective distances are *ab* and *ac*.

a. To plot map position, rectangular coordinates of which are given.—(1) Locate on the map the base position (origin) given.

(2) Through the base position draw a guide line parallel to the base direction.

(3) Through the base position draw a guide line at right angles to the base direction.

(4) From the base position along these lines point off to scale the respective distances in the respective directions as given.

(5) Treat these distances as the adjacent sides of a rectangle; complete the rectangle (other two sides) with construction lines. The intersection of these two construction lines is the point sought.

b. To determine rectangular coordinates of map position with respect to given base position and direction.—(1) Identify on the map the given point and the given base position.

(2) Through the base position draw a guide line parallel to the base direction.

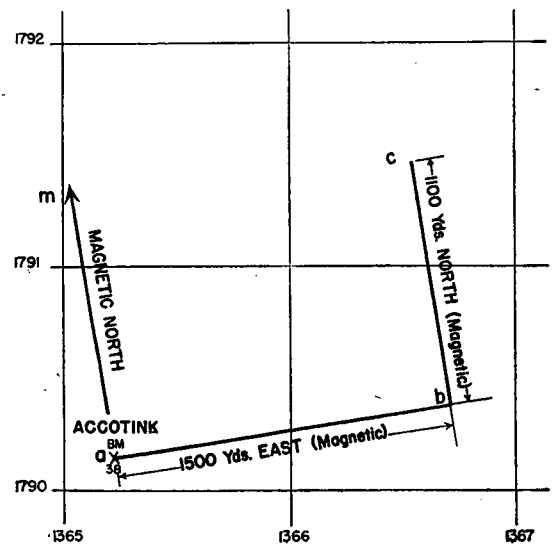

FIGURE 25.—Rectangular coordinates: BM 38, Accotink (village), distance 1,500 yards east magnetic, 1,100 yards north magnetic.

(3) Through the base position draw a guide line at right angles to the base direction.

(4) Through the given point drop perpendiculars to the lines established in (2) and (3) above.

(5) From the base position scale the distance along the guide lines of (2) and (3) above to the respective perpendiculars. These distances are the rectangular coordinates sought.

■ 32. GEOGRAPHIC COORDINATES.—The system of latitude and longitude lines projected on a map represents the geographic or spherical grid covering the earth. In this system the base position (or origin) is the intersection of the meridian of Greenwich, known as the prime meridian, with the Equator. The base direction is true north (or south). Distance on the spheroid (earth) is reckoned in units of degrees, minutes, and seconds of latitude up to 90° north or south of the Equator, and in degrees, minutes, and seconds of longitude up to 180°, east or west of the prime meridian. The location of any point on the surface of the earth is defined in terms

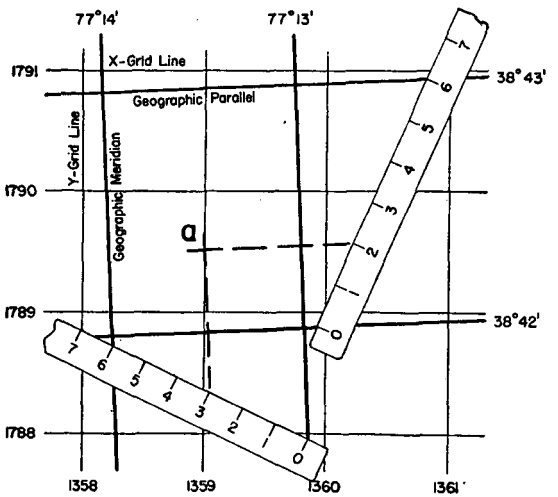

FIGURE 26.—Geographic coordinates: latitude 38°42'20" N., longitude 77°13'30" W.

of the parallel of latitude and the meridian of longitude which intersect at the point, thus, latitude 38°32'20" N., longitude 77°34'30" W. The latitude and longitude of a point constitute its geographical or spherical coordinates. However, meridians of longitude converge at the poles. Therefore, units of longitude decrease in units of linear distance from a maximum at the Equator to zero at the poles. Since the sphere cannot be developed as a plane, other variations are introduced in maps by the chracteristics of pro-

jections used in map construction. While units of latitude and longitude can be converted to distances in meters, yards, miles, etc., by computation or use of tables, the spherical units would not occur, except by fortunate coincidence, in rational multiples of the linear unit. Lines of the spherical grid are necessarily curves or projections of curved lines and vary with latitude and projection. Such variations from straight lines and true distances within the scope of a sheet of the terrain or the tactical map are negligible. For practical map-reading purposes they may be disregarded and the spherical grid may be treated graphically in all respects as a rectangular grid. The 5-minute lines of the geographic grid appear in full or by border registration on topographic sheets. The 1-minute lines of the geographic grid appear registered on some large-scale maps by border ticks and grid intersections. Geographic coordinates are used in designating positions in large indefinite areas, in unmapped areas, and on geographic (ungridded) maps.

a. To plot positions of point, geographical coordinates of which are given.—(1) Identify on the map the two lines of the geographic grid, both of latitude and longitude, which fall nearest to and on each side of the position to be plotted. This may be readily done by inspection of the map in comparison with the given coordinates. In case the lines of the grid do not appear in full on the map, draw in the lines by joining the border ticks and grid intersections. In either case the point sought falls somewhere within the quadrangle whose sides are lines (arcs) of known latitude and longitude. For a battle map (1: 20,000), this is a 1-minute quadrangle (60 seconds by 60 seconds). For a topographic sheet, this is a 5-minute quadrangle (300 seconds by 300 seconds).

(2) The problem then reduces itself to the mechanical operation of dividing the quadrangle into seconds of longitude and seconds of latitude, pointing off the seconds place required by each coordinate. One of these points will fall on the meridian of longitude which passes through the point sought. The other will fall on the parallel of latitude which passes through the point sought. The significant parallel of latitude and meridian of longitude are now struck in as guide lines. Their intersection is the point sought.

(3) Points on the significant parallel of latitude and meridian of longitude are readily located with the engineer's scale

used as a diagonal scale of proportional parts between the available grid lines. For the 1-minute grid the scale should be placed across the lines at any angle so that 60 convenient divisions span the distance. For the 5-minute grid 300 divisions of the scale should span the distance between lines. In each case each division of the scale indicates a second of latitude or longitude, depending upon which coordinate is being plotted.

(4) Figure 26 illustrates the location of a point *a*, the geographic coordinates of which are latitude 38°42′20″ N., longitude 77°13′30″ W.

b. To determine geographic coordinates of map positions.—(1) By inspection of the map, identify the grid quadrangle in which the point lies, drawing in the sides of the quadrangle when the grid appears registered only. The value in degrees and minutes of the meridians of longitude and parallels of latitude which form this quadrangle appears in print on the borders of the map. The problem, then, is to determine the position of the point within the quadrangle in seconds of latitude and seconds of longitude.

(2) Use the engineer's scale as a scale of proportional parts as described in *a*(3) above to establish the seconds lines within the significant quadrangle, except in each case (the two positions of the scale, one for latitude and one for longitude, respectively) the scale should pass through the point whose coordinates are desired. The number of seconds sought may now be read directly from the edge of the scale at the point in the direction of increasing grid values within the grid quadrangle. This added to the recorded value in degrees and minutes of the side of the significant quadrangle lowest in value yields the coordinate sought in degrees, minutes, and seconds.

■ 33. GRID COORDINATES.—*a. General.*—(1) In order to provide a standardized system of rectangular coordinates which are easy to read, the military grid is printed upon the map. The grid is composed of a set of parallel grid north and south lines showing distances in thousands of yards grid east of the origin, and a set of grid east and west lines showing distances in thousands of yards grid north of the origin of coordinates for the grid zone. The distance of any point grid east of the origin is called the *X*-coordinate. The distance

of any point north of the origin is called the *Y*-coordinate. In writing coordinates the *X*-coordinate is written first and the *Y*-coordinate last, with a dash between, and the whole inclosed within parentheses. Thus in figure 27 point *A* is located at (198–262). The coordinates are read in the same manner as they are written. In locating a point the key phrase "READ—RIGHT—UP" should be remembered.

(2) Coordinates are written and read to 1,000 yards and decimal parts thereof. In figure 27 the coordinates of point *B* are (197.8–263.7).

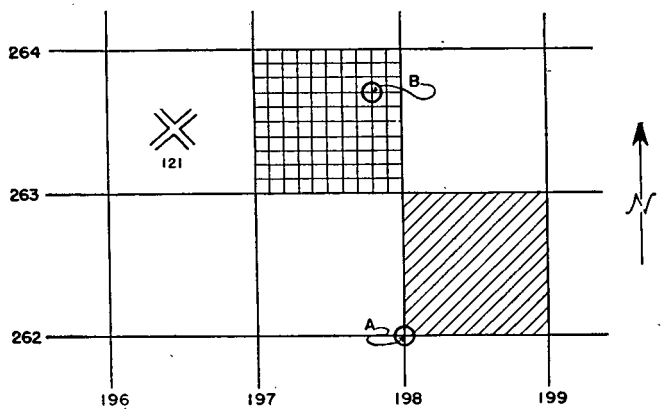

FIGURE 27.—Coordinates.

(3) It is customary to drop all but the last two digits; hence the coordinates of point *B* may be written or read (97.8–63.7).

(4) When a point is easily identified and only one of such exists within the grid square, it is necessary merely to refer to the southwest corner of the grid square in which it is located. For example, in figure 27 crossroads 121 could be designated as "CR 121 (96–63)."

b. Coordinate scale.—The use of the coordinate scale in reading or plotting the coordinates of a print on a map is explained in detail in FM 21–25.

c. Coordinates with engineer's scale.—The engineer's scale or any other suitably graduated scale may be used conveniently as a scale of proportional parts to plot a point within

the significant grid square. Let it be required, for instance, to plot a point *N*, the coordinates of which are (25.35–76.60) (fig. 28). Select any 10 equal subdivisions on the scale such that their total length is equal to or slightly greater than the grid interval on the map. Lay the scale on the map in position ① shown in figure 28 so that the zero is on the 25,000 grid line and the 10 is on the 26,000 grid line. Mark on the map the point *a* at 3.5 on the ruler. Slide the scale down to position ② and again mark on the map the point *a'* at 3.5 on the scale. Draw the line *aa'*. Now place the scale on the map in position ③ so that the zero is on the 76,000 line and

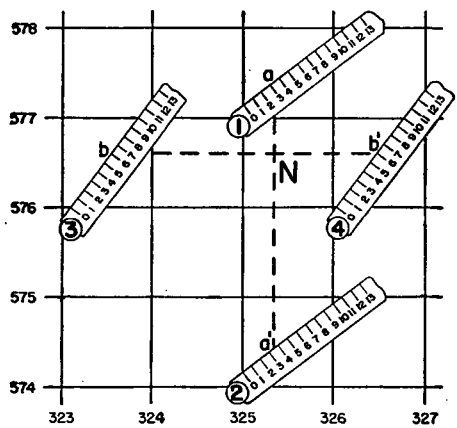

FIGURE 28.—To plot position of point (25.35–76.60) with engineer's scale on terrain map (1: 20,000) having 1,000-yard grid. (Not reproduced to scale.)

the 10 is on the 77,000 line. Mark on the map the point *b* at 6.0 on the scale. Slide the ruler to the right to position ④ and again mark on the map the position *b'* at 6.0 on the scale. Draw the line *bb'*. The intersection of the lines *aa'* and *bb'* is the plotted point *N* required. If desired, the subdivisions may be further subdivided into 10 equal parts, as on the engineer's scale, to give the position of the point by grid lines of 10-yard intervals. It can be seen that reading coordinates with the engineer's scale is accomplished in the same manner. (See fig. 29.)

■ 34. MILITARY GRID SYSTEM.—*a.* The standardized system of rectangular coordinates discussed in paragraph 33 is the grid system devised for use on military maps in order to avoid the difficulties and inconveniences inherent to the spherical grid. A rectangular grid superimposed on a polyconic projection of the whole continental United States would prove no more useful than a map on that projection and for the same reasons. Distances on the rectangular grid would vary prohibitively from true ground distances in the distorted areas near the edges of the map. However, by limiting the width of the projection to about 9° of longitude, the maximum distortion along the edge of the projection never exceeds 2.57 yards per 1,000 yards, or about ¼ of 1 percent, an error of

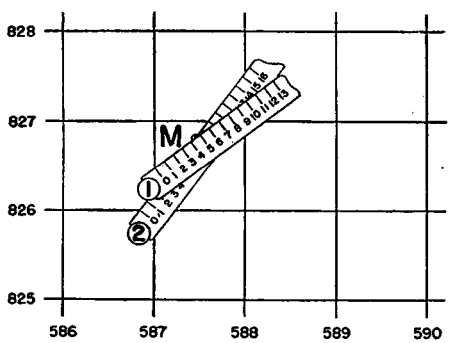

FIGURE 29.—To read grid coordinates of point (87.45–26.80), on terrain map (1: 20,000 scale) having 1,000-yard grid, with engineer's scale.

no military consequence, since the changes in dimensions of an ordinary map sheet due to weather conditions may exceed that amount.

b. For the purposes of superimposing the rectangular grid, the northern half of the continental Western Hemisphere has been divided into seven zones, each 9° of longitude wide. Each zone is a separate polyconic projection. When the military grid system was first established it extended from 28° N. latitude to 49° N. latitude. This system, known as the continental system, was sufficient for continental United States only. Later, in order to take care of Panama and the Caribbean area, the equatorial system, extending from

7° N. to 28° N., was set up. These two systems have different *Y* origins, and hence any point in this area will have the same *X*-coordinate in both systems but different *Y*-coordinates. All grids are identical in structure but each has a separate origin 8° of longitude distant from its neighbor.

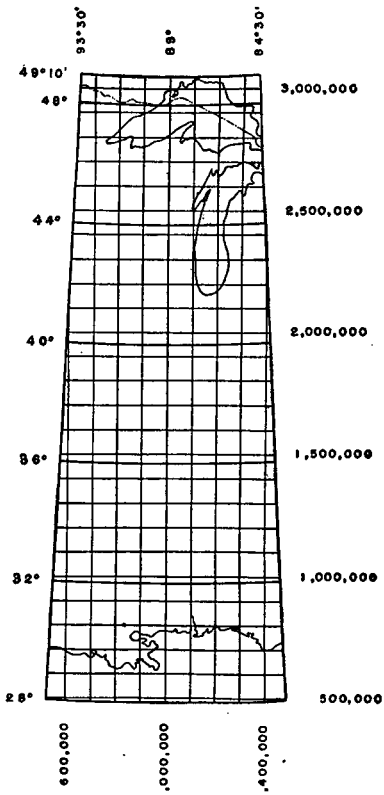

FIGURE 30.—Special military map of continental system grid zone C.

The grids therefore overlap 1° of longitude along the borders, with a net width of 8° of longitude between the central meridians of the overlaps. These zones are designated by a letter in accordance with the following table, that portion

TABLE III.—*Grid zone systems in northern half of continental Western Hemisphere*

Zone	Limiting meridian of zones	Origin of coordinates X	Grid values assigned to origin X yards	Equatorial system		Continental system	
				Origin of coordinates Y	Grid values assigned to origin Y yards	Origin of coordinates Y	Grid values assigned to origin Y yards
A	68°30′ W., 77°30′ W	73° W	1,000,000	Equator	Zero	40°30′ N	2,000,000
B	76°30′ W., 85°30′ W	81° W	1,000,000	do	do	40°30′ N	2,000,000
C	84°30′ W., 93°30′ W	89° W	1,000,000	do	do	40°30′ N	2,000,000
D	92°30′ W., 101°30′ W	97° W	1,000,000	do	do	40°30′ N	2,000,000
E	100°30′ W., 109°30′ W	105° W	1,000,000	do	do	40°30′ N	2,000,000
F	108°30′ W., 117°30′ W	113° W	1,000,000	do	do	40°30′ N	2,000,000
G	116°30′ W., 125°30′ W	121° W	1,000,000	do	do	40°30′ N	2,000,000

of the State of Maine falling to the east of longitude 68°30′ being included in zone A.

c. The limits of the grid zones are shown in table III and illustrated in figure 31. The zone letter appears on all maps containing grids. In designating points by grid coordinates,

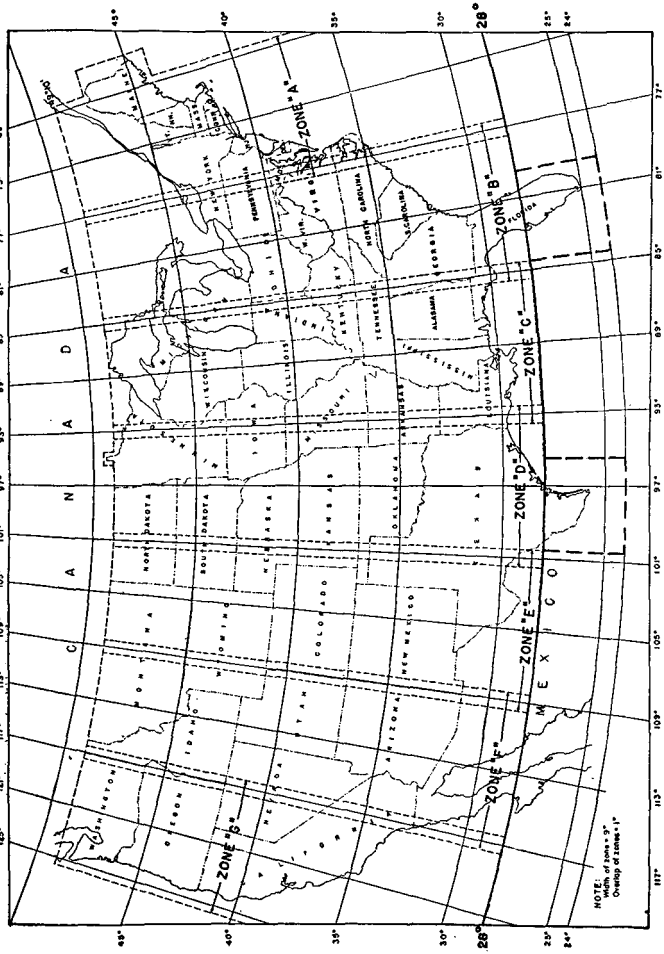

FIGURE 31.—Designation of military grid systems.

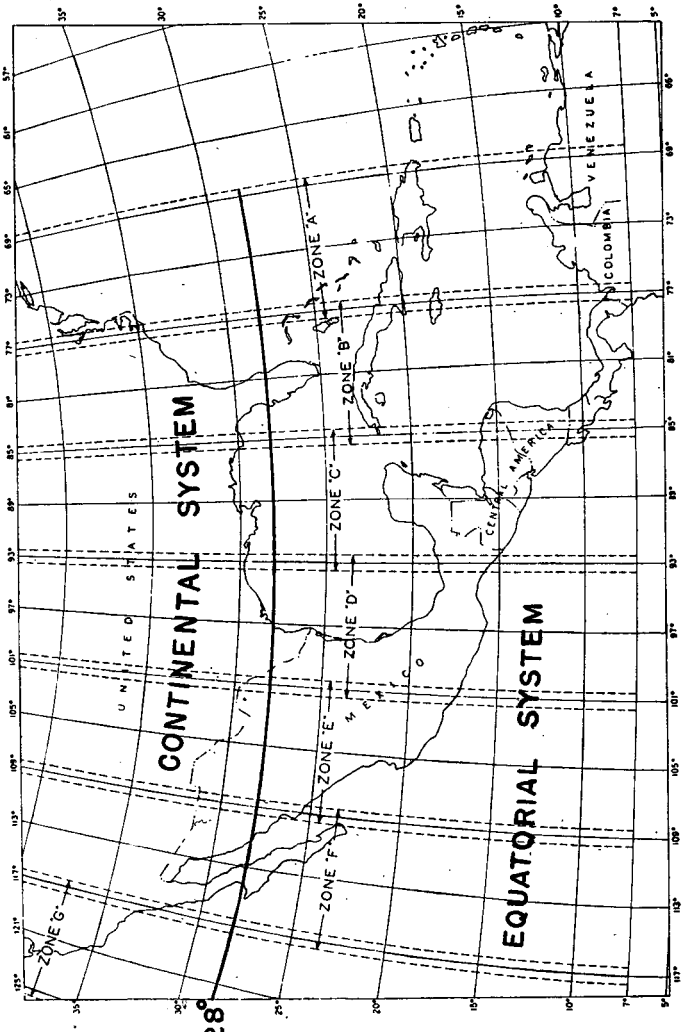

FIGURE 31.—Designation of military grid systems—Continued.

the name of the map sheet and not the zone letter should be used as primary reference.

■ 35. CONTINENTAL SYSTEM.—*a.* In each zone the intersection of its central meridian with the parallel of latitude 40°30′ is selected as the origin of coordinates designated by *O*. The central meridian is chosen as the *Y*-axis and a right line tangent to latitude 40°30′ at *O* is chosen as the *X*-axis. In terms of yards, the grid coordinates of all 5-minute intersections of latitude and longitude within the whole grid zone are computed with respect to these axes and the origin *O*. The coordinates of intersections in all other quadrants, except the first, involve some negative quantities which are undesirable for simplicity. In order to make positive all coordinates which appear on military maps embraced within the zone, the computed values are transferred to a new origin *O′* exactly 1,000,000 yards grid west and 2,000,000 yards grid south of the origin *O*. This is effected by simply adding 1,000,000 yards to all computed *X*-coordinates and 2,000,000 yards to all computed *Y*-coordinates. It is the point *O′* and axes *O′–X* and *O′–Y* to which all grids and grid values appearing on all military maps are related. The original origin *O* has no further significance. This scheme is shown in figure 30 and table III, and the rectangular grid system illustrated therein is referred to as the military grid system.

b. Since the grids for all zones are identical in structure, only one set of original computations suffices for all zones simply by changing in the tables the longitude values successively through 8°, 16°, 24°, etc., of longitude, respectively. (See Special Publication 59, U. S. Coast and Geodetic Survey.)

c. The military grid appears registered on gridded maps in two series of parallel lines at right angles to each other. On sheets of the terrain map (1: 20,000), these lines form 1,000-yard squares. On sheets of the tactical map (1: 62,500), these lines form 5,000-yard squares. The central meridian of the overlap between adjacent grid zones is the dividing line between the zones. Any map which falls within the 1° overlap between grid zones always shows in solid black lines the grid of the zone to which the map pertains. The grid of the adjacent overlapping zone may also appear registered by means of grid intersections (small crosses) on the face of the sheet and ticks around the border lines. The scheme is useful in effecting

transition of data from one zone to another. The lines of the overlapping zone when needed may be struck in by simply joining the registration points. Since the grid lines of each zone are all parallel to the central meridian of the zone and since meridians converge to the poles, the lines of overlapping grids will always cross at distinct angles.

d. The distance of each north and south grid line, grid east of the zero point or origin of coordinates, is marked in thousands of yards along the south border of a gridded map. The distance of each east and west grid line, grid north of the zero point or origin, is marked in thousands of yards along the west border of a gridded map. The numbers which identify the north and south grid line and the east and west grid line which intersect at or nearest to the southwest corner of a gridded map are written out in full in yards. In marking all other grid lines, the digits common to the sheet may be omitted. When the grid of an overlapping zone appears registered by ticks and grid intersection on a map, the ticks of the north and south and east and west grid lines, respectively, which intersect at or nearest to the southeast corner, are marked in full to yards. No other grid lines of the overlapping zone are marked.

e. By agreement with the War Department, sheets of the topographical atlas of the United States Geological Survey adopted as tactical maps will have the 5,000-yard grid registered by ticks along the borders.

NOTE.—The above methods of showing grids on a map are followed by the Corps of Engineers in the reproduction of all gridded maps. There are maps in common use for school purposes, such as the Gettysburg map, on which only a local grid system is used. The reader should not confuse such a grid with the military grid system.

■ 36. EQUATORIAL SYSTEM.—*a.* The equatorial system, using the same zones as the continental system, has the latitudinal origin at the Equator, and covers the area between the 7° N. and 28° N. parallels. The system is otherwise similar to the continental system. Tables and methods of computation for the equatorial system are found in Corps of Engineers publication "Grid System for Military Maps for 7° to 28° North Latitude."

b. In the overlapped areas below 28° N. in Texas and Florida, care must be taken not to confuse the two grid systems. In the absence of other data, it may be assumed

that the continental system is used within the limits shown on figure 31②.

■ 37. DETERMINATION OF UNKNOWN DIRECTIONS, DISTANCES, OR COORDINATES.—*a. To determine distance between two points, grid coordinates of which are given.*—(1) *Graphically.*—Plot

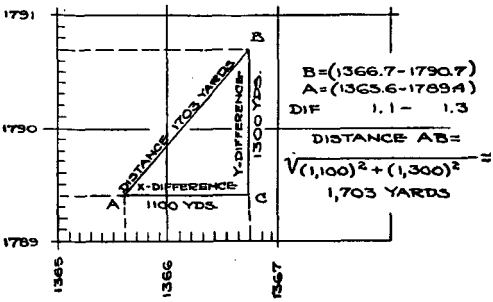

FIGURE 32.—Distance between two points on map by solution of right triangle.

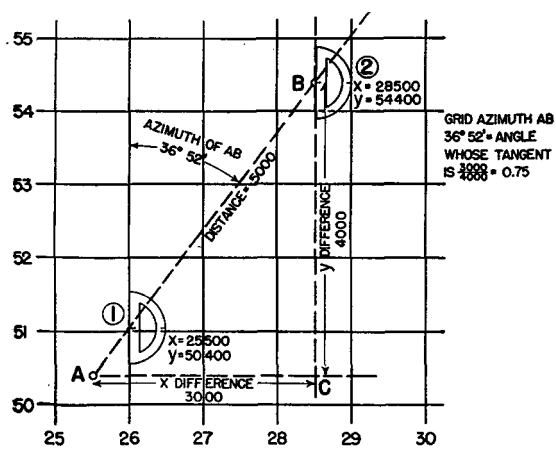

FIGURE 33.—Determination of grid azimuth of line on gridded map.

the positions of the two points on the map. If no map is available, plot the relative position of the points to scale on an improvised grid. In either case, scale directly the distance between the plotted points.

(2) *By solving right triangle* (fig. 32).—The distance between the two points is the hypotenuse of a right triangle whose legs are the differences, respectively, between the *X*- and *Y*-coordinates of the two points. The distance in yards is therefore the square root of the sum of the squares of *X* difference and *Y* difference. The method is completely illustrated in figure 32.

b. To determine grid azimuth of line between two points, grid coordinates of which are known (fig. 33).—(1) *From map.*—Plot the position of the two points *A* and *B* on the map or plot the relative position of the points on an improvised grid to scale as shown in figure 33. Join the plotted positions by a straight line and prolong if necessary to intersect a north-sound grid line. With a protractor, as shown in figure 33①, measure the angle from the north-south grid line clockwise to the straight line indicating the significant direction, bearing in mind that a line has two directions differing in azimuth by 180°.

(2) *By plotting right triangle.*—Plot to scale on plain or cross-section paper or the gridded map the right triangle whose legs are the *X*-difference and the *Y*-difference of the given coordinates of the respective points which may be represented by *A* and *B* in figure 33. In the triangle *ABC* so formed, *CB* is the base or grid north direction. With the protractor at *B* (fig. 33②), measure clockwise the angle from *CB* prolonged either to *AB* prolonged or to *BA*, depending upon which azimuth (differing by 180°) is required.

(3) *By trigonometric functions* (fig. 33).—(*a*) The grid azimuth sought is, by inspection of the figure, seen to be equal to the angle *ABC*, whose tangent is

$$AC/BC=\frac{X\text{-difference}}{Y\text{-difference}}=3{,}000/4{,}000=0.75$$

(*b*) From a table of natural tangents this corresponds to the angle 36° 52′, which is the grid azimuth of the line in the first quadrant.

(*c*) In the SE quadrant subtract this angle from 180°, in the SW quadrant add to 180°, and in the NW quadrant subtract from 360°.

(*d*) The method is useful when the points fall on separate sheets or the map is distorted.

c. Determination of coordinates of point when distance and directions are given from point with known grid coordinates.—

When the distance between two points is comparatively great or lie on sheets of a different scale, the coordinates of one are established mathematically from the one with known coordinates as follows:

(1) Convert direction into bearings using grid north (see par. 21).

(2) Look up sine and cosine of the angle and multiply by the distance.

(3) The sine multiplied by the distance will give the east or west distance to be added algebraically to the first coordinate given; an east bearing is plus; a west bearing is minus.

(4) The cosine multiplied by the distance will give north or south distance to be added algebraically to the last coordinate given; a north bearing is plus; a south bearing is minus.

(5) *Example* (fig. 34).

Given: Coordinates of point *a* (898–252).
Direction of line from *a* to *b*=magnetic azimuth 317° 28′.
Grid declination 9°31′.
Distance 9,720 yards.

Required: Coordinates of point *b*.

Solution: Grid azimuth=317°28′ plus 9°31′=326°59′.
Bearing=360° minus 326°59′=N. 33°01′ W.
From tables of natural trigonometric functions—
Sine 33°01′=0.54488.
Cosine 33°01′=0.83851.
0.54488 times 9,720=5,296 yards.
0.83851 times 9,720=8,150 yards.
Coordinates (898–252 mean 898,000 yards east of basic origin and 252,000 yards north of basic origin.
Since the bearing of the line is N. 33°01′ W. (IV or NW quadrant).
898,000—5,296=892,704 yards.
252,000+8,150=260,150 yards.
Hence coordinates of point *b* are (892.7–260.2).

d. To superimpose grid on map from point with known grid coordinates (fig. 35).—Establish, by some means previously

mentioned, the grid north on the map. Draw lines *N—S* and *E—W* through the known point. Along these lines scale off the desired grid spaces. Extreme care should be exercised in establishing a grid from one point to insure accuracy.

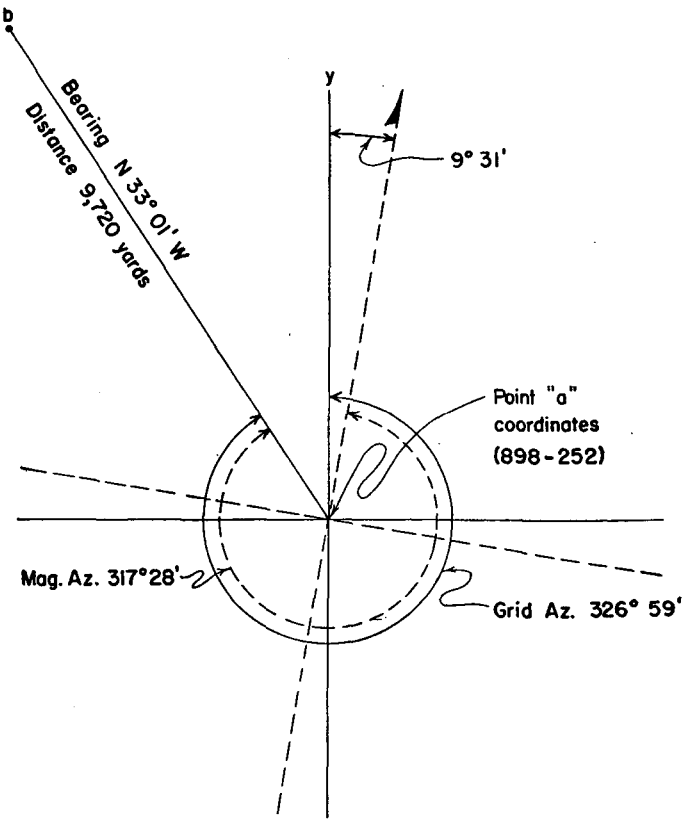

FIGURE 34.—Grid coordinates from known point.

When some other point of known coordinates exists on the map a check should be made with it.

■ 38. CONSTRUCTION OF MILITARY GRID FROM GEOGRAPHIC COORDINATES.—For transformation of geographic coordinates

to grid coordinates, or vice versa, see United States Coast and Geodetic Survey Special Publication No. 59 and "Grid System for Military Maps for 7° to 28° North Latitude"; paragraph 61, TM 5–230; and paragraph 117*f*, TM 5–235.

SECTION V

ELEVATION AND RELIEF

■ 39. ELEVATION.—Elevation is the measure of vertical distance from a known datum plane. For most maps the datum

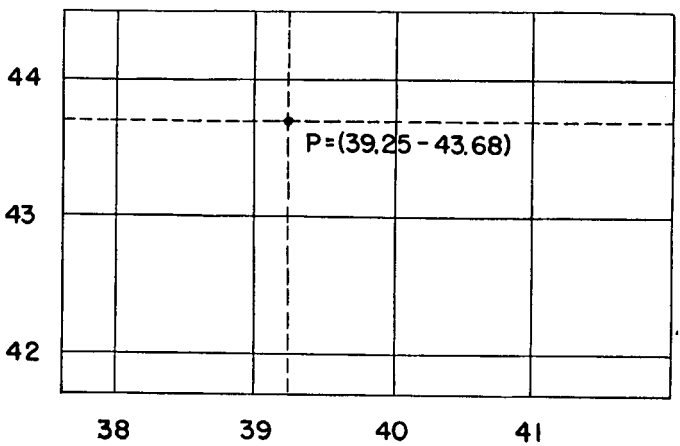

FIGURE 35.—To superimpose a grid on a map from a point with known coordinates.

is mean sea level and zero elevation. Elevation is expressed in feet above or below mean sea level. When above mean sea level, elevation is plus; when below mean sea level, elevation is minus. Where no indication is given the elevations are always taken as plus.

■ 40. RELIEF.—*a.* The variation in the height of the earth's surface, as ridges, valleys, etc., is termed "relief." As the exact nature of the terrain has a marked influence on military operations, it is important that the military commander of every unit familiarize himself with the "lay of the land" in which he is operating. This familiarity cannot always be

obtained by actual reconnaissance beforehand but often must be gained solely by study of topographic maps. The map, then, must convey to the map reader a definite impression of the ground forms. The ability to comprehend relief from the map requires an understanding of the way in which the various ground forms have been produced by nature.

b. There is a considerable degree of regularity and system in ground forms, due to erosion. Not all the water from heavy rains can seep into the soil; much of it runs off. At one point a little stream begins; as it flows downward another joins it; soon several unite into a fair-sized creek, which rushes along, carrying its burden of soil into the main valley, whence the river may carry it into the sea. This simple process, continued for ages, has sufficed to carve the surface of the earth into the form we find today.

c. Since most of our present ground forms are the result of erosion, it is evident that the drainage scheme of an area is the key to its topography. On maps where streams are indicated and on aerial photographs, this key is in evidence; converging streams show a general slope to a valley; diverging fingers of streams portray a crest or ridge. The drainage net and ridge lines constitute the "master lines" of the terrain. Points of change in horizontal or vertical direction of these lines are known as "critical points." Getting the "lay of the land" consists of grasping the significance of these master lines. The method adopted for showing relief on a map must be one which will convey to the map reader an immediate conception of the drainage and ridge lines of the system of relief.

■ 41. METHODS OF REPRESENTING RELIEF.—Since the map is flat, special conventional signs are necessary to show relief. The most common methods used on maps are as follows:

a. Hachures (fig. 36).—A method frequently used to indicate relief in a general way is by the use of hachures. It is particularly useful when the available data are inadequate for the more accurate representation of relief by contours, or when the purpose of the map does not justify the more complicated and time consuming methods. This method of representing relief has been adopted for the Strategic Map of the United States (scale 1:500,000) and will be frequently found on large as well as small scale foreign maps. Hachures

are short parallel or slightly divergent lines drawn in the direction of slopes, closely spaced on steep slopes, wide apart on gentle slopes, and convergent toward the tops of ridges and hills. The resulting shadow effect gives an excellent pictorial representation of hilltops, ridges, and valleys, and enables the map reader to gain a fair conception of the relative slopes of various parts of the terrain.

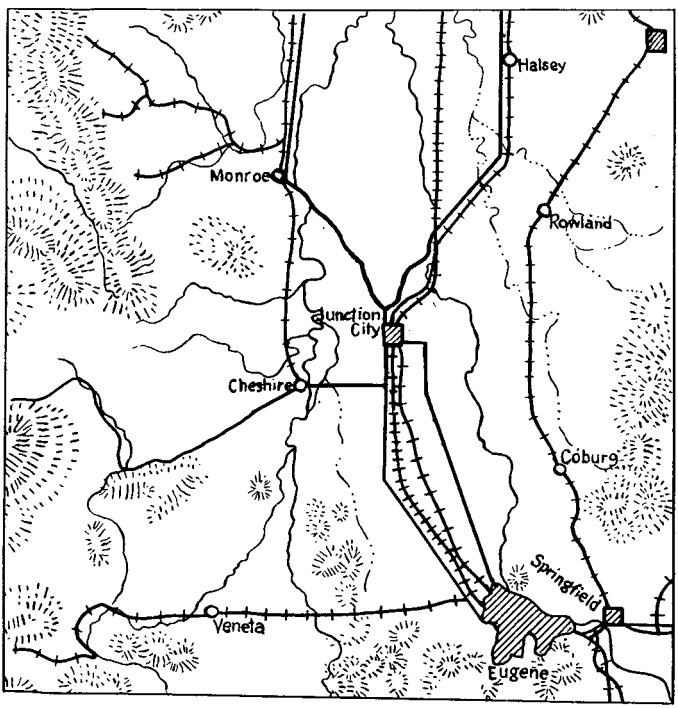

FIGURE 36.—Relief by hachures.

b. Color-layer system.—Color-layer systems of relief representation consist of using different colors or different tones of the same color to distinguish different zones of elevation. These resulting color bands are bounded by contours which are usually shown on the map. Contours falling within color zones are usually omitted. A key to the color system showing

the succession of colors and the elevation zones to which they pertain is given on the map margin. The colors of the elevation gradient should be selected to produce a harmonious effect but there should be sufficient contrast between the colors to insure ease of reading. This method is used on aerial navigation charts published by the Army. The color gradient used on these maps is shown in FM 21–30.

c. Contours.—A contour line represents an imaginary line on the ground, every part of which is at the same elevation usually applied to mean sea level. Such a line could be drawn at any altitude but in mapping only the contours at regular intervals of altitude are shown. The line of the seacoast itself is on the zero contour line if mean sea level is assumed to be the zero datum plane. If the sea should rise 20 feet above mean sea level, the new seacoast line would then be on the 20-foot contour line. Contour lines show the shapes of the hills, mountains, and valleys, as well as their altitudes. Successive contour lines that are far apart on the map indicate a gentle slope; lines that are close together indicate a steep slope; and lines that run together indicate a cliff. Contour lines never cross except in the case of an overhanging cliff. The sketch in figure 37① represents a river valley that lies between two hills. In the foreground is the sea, with a bay that is partly inclosed by a hooked sand bar. On each side of the valley is a terrace into which small streams have cut narrow gullies. The hill on the right has a rounded summit and gently sloping spurs separated by ravines. The spurs are truncated at their lower ends by a sea cliff. The hill at the left terminates abruptly at the valley in a steep scarp from which it slopes gradually away and forms an inclined tableland that is traversed by a few shallow gullies. The manner in which contour lines express altitude, form, and grade is shown in figure 37②. Each feature shown in figure 37① is represented on the contour map (fig. 37②) directly beneath its position in figure 37①.

d. Depth curves.—A contour showing points of equal elevation below the level of any body of water is called a depth curve. These curves will indicate depths below a certain datum, usually mean low water level for the body of water concerned. The vertical interval is frequently expressed in fathoms (6 feet).

■ 42. CHARACTERISTICS OF CONTOURS.—In order to appreciate the representation of relief and elevation differences by contours, study must be given to the basic characteristics of them. FM 21–25 describes very thoroughly these characteristics. Briefly, it may be observed that contours on a map—

a. Are wavy in appearance.

b. Are usually V-shaped in narrow valleys and U-shaped on noses of hills.

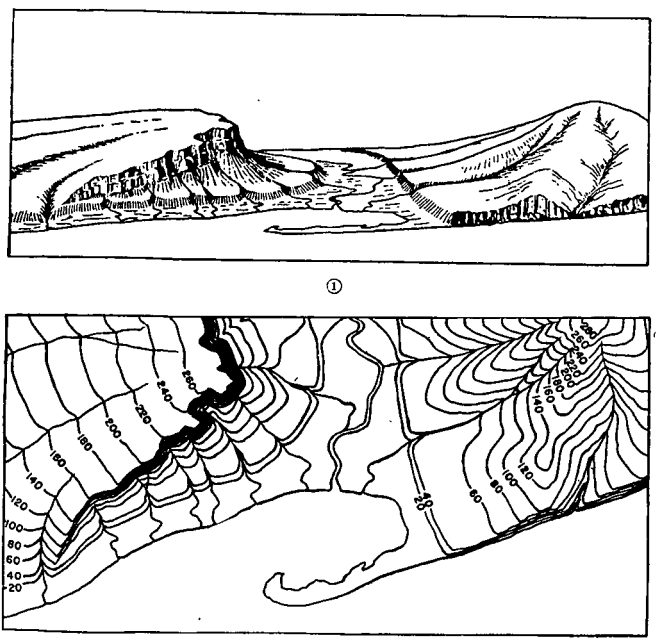

FIGURE 37.—Relief by contours.

c. Always close, on or off the map.

d. Are at right angles to the lines of steepest slope.

e. Are spaced directly as the variation of the slope; close on steep slopes, far apart on gentle slopes.

f. Are roughly parallel to the adjacent contour lines. Figure 38 shows the relation of profile to contours.

■ 43. CONTOUR INTERVAL.—*a.* The contour interval, or the vertical distance in feet between one contour and the next, is stated as marginal information, usually under the scale, at the bottom of each map. This interval differs according to the topography of the area mapped and the scale of the

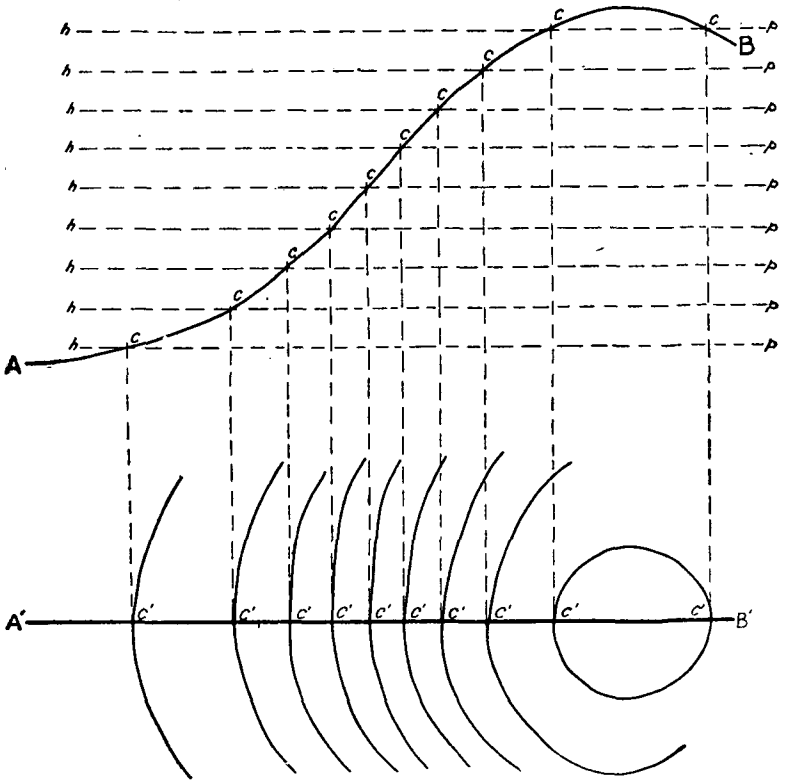

FIGURE 38.—Relation of profile to contours.

map; in a flat country it may be as small as 1 foot; in a mountainous region it may be as great as 250 feet.

b. For military use it is necessary that the various sheets of a map of any given area have a common scale and contour interval or intervals that match. In order that peacetime

practice throughout the United States be consistent, the War Department (AR 300–15) and the United States Geological Survey have adopted the following contour intervals for standard quadrangle maps. The intervals in general conform to contour intervals found on most existing topographic maps.

(1) Contour intervals of 5, 25, 50, or 100 feet in the States which lie all or mostly west of longitude 103° as follows: Washington, Oregon, California, Idaho, Nevada, Utah, Arizona, Montana, Wyoming, Colorado and New Mexico.

(2) Contour intervals of 5, 10, 20, 40, or 100 feet in the States which lie all or mostly east of longitude 103°. The 5-foot contour interval is used only on large-scale maps of limited areas.

c. On most maps every fifth contour line is made heavier than the others and is accompanied by figures showing the altitude at convenient intervals.

■ 44. ELEVATIONS OF IMPORTANT FEATURES.—The elevations of important features such as road junctions, summits, and surfaces of lakes, called spot heights, and those of bench marks are given on the map in figures to the nearest foot. More exact altitudes of bench marks are published in bulletins that are issued by the Geological Survey and the Coast and Geodetic Survey. On coastal charts the datum is mean low water.

■ 45. INTERPRETATION OF RELIEF BY CONTOURS AND MARKED POINTS OF ELEVATION.—*a.* Further understanding of the means of representing and interpreting relief and elevation on maps may be obtained from a study of the sketch represented in figure 39. This shows a section of a map contoured with a vertical interval of 20 feet.

b. The numbers along the edge of the sketch represent the respective elevations of the contours above mean sea level. By following the several contours across the sketch the elevations of various points may be determined. By study of the contour net as a whole the relief of the ground may be interpreted quickly by the practiced map reader. Thus the closed contours at points *X*, *Y*, and *Z* indicate hilltops. The numbers indicate that these hills are at elevations of 1,110, 1,130, and 1,105 feet, respectively. In speaking of unnamed hills on a topographical map, they are referred to by use of

their elevation; for example, hills *Y* and *Z* would be designated hill 1,130 and hill 1,105, respectively.

c. A further study of the sketch will indicate how the various terrain features are recognized. Point *K* represents a saddle between hills *X* and *Y*. It is also the watershed between the head of the stream system at *P* and the slope toward the bottom of the sketch from point *A*. The elevation of point *K* is approximately 1,030 feet (being between the 1,020- and 1,040-foot contours). Point *N* between hills *Y* and *Z* represents a saddle at an approximate elevation of 1,090

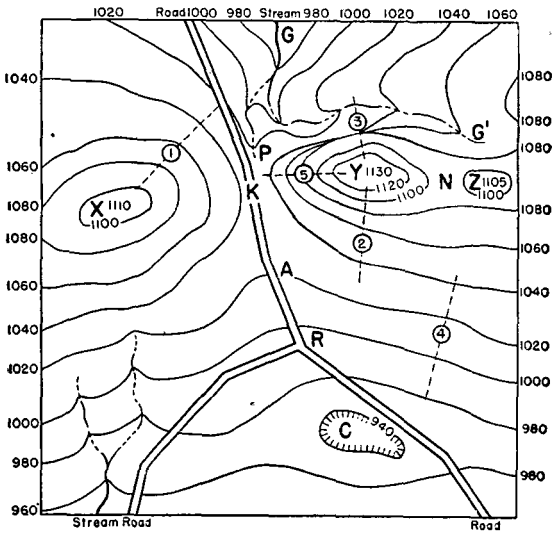

FIGURE 39.—Interpretation of relief.

feet. Along the dotted line ①, the uniform spacing of the contours and their distance apart indicate a uniform, gentle slope. Along the dotted line ②, the spacing of the contours is irregular, indicating varying slopes. Along the dotted line ③, the slope is steep, terminating in a cliff where the contour lines meet each other. Along the dotted line ④, the contours, being almost straight, nearly parallel and quite far apart, represent a very gently sloping plane surface. Along the nose indicated by the dotted line ⑤, the contours

are U-shaped with the botton of each U pointing down hill. Where the contours cross the stream valley G–G', they run up the valley on one side of the stream, turn in a sharp V and run back down on the other side; the bottom of the V formed at the stream crossing points up stream in contradistinction to the U's of the contours on the shoulder of the ridge at ⑤.

d. Since on maps, road junctions usually are given a number corresponding to their elevations above sea level, the road junction at *R*, about halfway between contours 980 and 1,000, would be designated *RJ* (road junction) 990. Crossroads are designated *CR* (followed by the elevation in the same way).

■ 46. APPROXIMATE CONTOURS AND FORM LINES.—*a. Approximate contours.*—When it has not been possible for the topographer to locate accurately contours for a map, they are shown to be approximate only by the use of broken lines.

b. Form lines.—Form lines are similar to contours in that they are drawn at right angles to the direction of steepest slope. However, form lines have no fixed interval and do not indicate elevations. Their purpose is to show the configuration of the ground.

■ 47. LOGICAL CONTOURING.—*a.* In mapping, contouring may be done by the topographer in the field by one of several methods:

(1) He may actually run out the location of the contours on the ground. This method is applicable to large-scale maps when great accuracy is desired and the expenditure of time and labor is economically justified.

(2) He may run out enough contours to define the ground forms and interpolate between them by eye.

(3) He may run out only stream and ridge lines, getting elevations on these lines at each change of slope or ground form. Such elevations defining the ground forms are known as "critical elevations." The contours may then be sketched in the field by eye between critical elevations. This method is the cheapest, quickest, and most commonly used.

b. Logical contouring may best be explained by an illustrative example. In figure 40① critical elevations have been measured by the topographer. The problem is to interpolate

10-foot contours so that the ground forms depicted will be logical.

(1) First, along the main stream, interpolate the elevations of all stream junctions not shown by assuming that the stream has a uniform slope between critical points. For example, there is a stream junction of unknown elevation

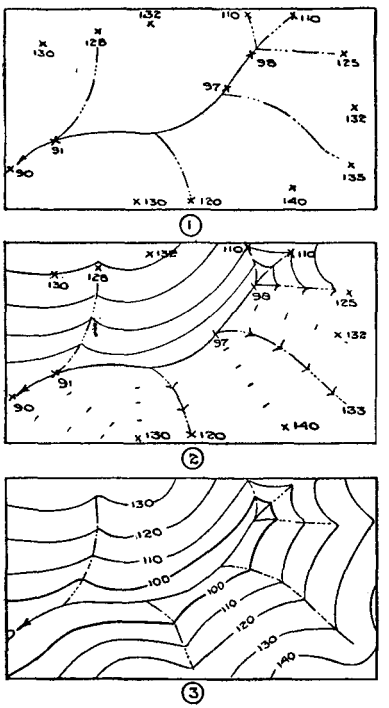

FIGURE 40.—Method of drawing contours by interpolation on drainage net where elevations are given.

between elevations of the stream of 91 and 97 feet, respectively. Between these two points the stream rises 6 feet. Because the stream junction, the elevation of which is sought, is approximately half the distance measured along the stream between elevations 91 and 97, it is assumed that the stream

has risen to that point only one-half of 6, or 3 feet. The elevation sought is therefore 94 feet.

(2) In this way, interpolate elevations which are multiples of 10 feet on all the streams. These are the points where contours cross the stream and are shown as V-shaped marks pointed upstream as in figure 40②.

(3) By interpolation between critical elevations determine where 10-foot contours round the ridges and indicate by lightly drawn U's. Since hills are normally rounded at top and slope off gradually at the bottom with the steepest rise on the slope of the hill (fig. 38), contours will have slightly closer spacing on the rise than at the crest or bottom.

(4) By building up one ground form at a time, connect the V's and U's with smooth contours as shown in figure 40③. Each spur between two streams in the illustration should be drawn in separately.

(5) Every fifth contour (starting from 0) should be made heavier than the rest and should have the elevation written on it.

c. The contours should be sketched while in the field. However, if enemy action or other cause makes this impossible, contours may be interpolated in the office, preferably with the aid of aerial photographs and a stereoscope, provided that critical points have been adequately determined.

■ 48. DETERMINATION OF ELEVATION.—*a.* In the discussion in paragraph 45, approximate elevations of specific points on the map were determined roughly by inspection. Where more accurate elevations are desired, some means of interpolation between contours becomes necessary. In the following procedure the refinement is for theoretical purposes only. Any interpolation from contours is an approximation upon which undue refinement may be misleading.

b. Refer to the margin of the map. To determine the elevation of any specific point, proceed as follows (fig. 41):

(1) If the point falls on a heavy contour, it is only necessary to follow that contour until the elevation appears and read it. For example, the elevation of the point *B* in the figure is read directly as 1,300 feet.

(2) If the point falls on a light contour, the elevation is found by reference to the adjacent heavy numbered contour

lines and interpolating. For example, the elevation of the point *A* is 1,260 feet.

(3) When the point lies between two contours as at *C* in figure 41—

(*a*) Find the elevation of the nearest contour line.

(*b*) Measure the shortest distance between the two adjacent contours along a line passing through the point *C*.

(*c*) Measure the distance along this line from the point in question to the nearest contour.

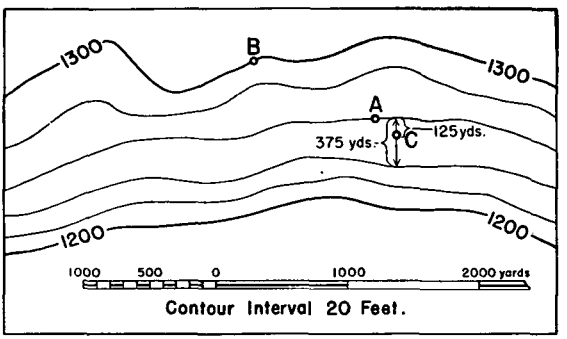

FIGURE 41.—Determination of elevation on contoured map.

(*d*) Solve the following equation:

$$\frac{\text{Distance from point to nearest contour}}{\text{Distance between contours}} \times \text{contour interval} = \text{difference in elevation between point in question and the nearest contour.}$$

Since the distance between adjacent contours at this place is 375 yards and since *C* is 125 yards from the nearest contour (the 1,260 contour), entering the equation given above,

$$\frac{125}{375} \times 20 \text{ feet} = 6\tfrac{2}{3} \text{ feet.}$$

Taking the nearest whole number of feet (7), the elevation at point *C* is 7 feet less than the elevation of the nearest contour, or 1,260—7=1,253 feet. If the nearest contour is of lower elevation than the point in question, the difference in elevation must of course be added.

(4) When a point, the elevation of which is required, lies within a closed contour forming the top of a hill or the bottom of a depression, only an approximation of its actual elevation is possible.

SECTION VI

SLOPE, PROFILE, AND VISIBILITY

■ 49. SLOPE.—The inclination of the land surface relative to a horizontal plane is the slope, and slope is a function of two factors—horizontal distance and vertical distance. Two points are therefore necessary to determine these factors. The vertical distance is the difference in elevation of the points and on a contoured map may be interpolated from the contours. The horizontal distance is scaled from the face of the map. Along a straight line it is the scaled length of the straight line. Along a meandering stream, irregular road, or broken line, it is the scaled length of the meander line or other irregular distance under consideration. Both horizontal and vertical distance must be expressed by the same units, preferably feet. Slope may be computed or measured and expressed in terms of percent, mils, degrees, or as gradient. The slope of roads, railroads, embankments, and cuts is referred to as grade. While the most commonly used method of expressing slope is by percent, the advanced map reader should be familiar with other methods.

■ 50. SLOPE IN PERCENT.—Percent is the most convenient and commonly used method of expressing slope. A slope of 1 percent is a slope which rises vertically a distance of one unit in a horizontal distance of 100 units or one which has this rate of rise (fig. 43). A 2-percent slope rises two units, a 3-percent slope rises three units, and so on, in a horizontal distance of 100 units. The value in percent of any slope is the number of units which it rises vertically in a horizontal distance of 100 units. Thus a rise of 26.8 feet in a horizontal distance of 100 feet is a slope of 26.8 percent (fig. 42).

■ 51. SLOPE IN MILS.—The mil is a unit of angular measurement. A true mil is an angle which subtends an arc of unity at a radius of 1,000 units (fig. 43). A 2-mil slope subtends an arc of two units, a 3-mil slope subtends an arc of three units, and so on, at a 1,000-unit radius. The value of slope in mils

is therefore a function of the angle of slope. The vertical rise of a mil slope is not exactly equal to the subtended arc, the vertical rise of a slope of 2 mils is not exactly twice the vertical rise of a slope of 1 mil, and the variation increases with the angle of slope. However, for slopes up to 350 mils,

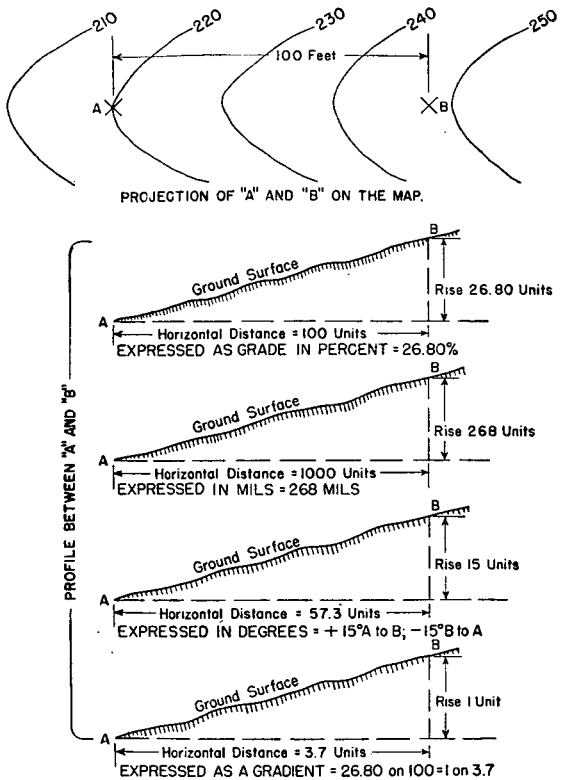

FIGURE 42.—Determination and expression of slope between two points *A* and *B* on map.

the variations are inappreciable and may be disregarded for average purposes. Thus a slope which rises 268 units in a horizontal distance of 1,000 units is a slope of 268 mils (fig. 42). Slopes may be measured with instruments graduated

in the arbitrary mil which is $\frac{1}{6400}$ of a circle. For ordinary slopes the results would not differ appreciably from the value in true mils, of which the circle contains approximately 6,283.

■ 52. SLOPE IN DEGREES.—Many instruments for measuring slope are graduated in degrees. The degree is a unit of angular measurement and is $\frac{1}{360}$ of the circle. A degree is an angle which subtends an arc of unity at a radius of approximately 57.3 units (fig. 43). A 2° slope subtends an arc of two units, a 3° slope subtends an arc of three units, and so on, at a 57.3-unit radius. The value of slope expressed in degrees is therefore a function of the angle of slope (fig. 42). The vertical rise of a degree slope is not exactly equal to the subtended arc, a slope of 2° is not exactly twice the vertical rise of a 1° slope, and the variation increases with the angle of slope. However, for slopes up to 20° the variations are negligible and may be disregarded.

■ 53. GRADIENT.—The gradient is the unit usually used in the measurement of steep slopes. It is the ratio of vertical to horizontal or of horizontal to vertical distance (fig. 42). The manner of expressing this ratio has not been standardized. Two methods are in common use as follows: A gradient of 1 on 3.7 and a gradient of 3.7 to 1.

■ 54. SLOPE BETWEEN TWO POINTS ON MAP.—*a.* Subtract the elevation of the initial point from the elevation of second point to determine the difference in elevation or vertical rise.

b. Scale from the map the horizontal distance between the two points along the line whose slope is to be determined and express in the same units of measurement, preferably feet.

c. Compute the value of slope from the appropriate one of the following formulas:

(1) Percent $= \frac{\text{difference in elevation} \times 100}{\text{horizontal distance}}$

(2) Mils $= \frac{\text{difference in elevation} \times 1{,}000}{\text{horizontal distance}}$

(3) Degrees $= \frac{\text{difference in elevation} \times 57.3}{\text{horizontal distance}}$

(4) Gradient $= \frac{\text{difference in elevation}}{\text{horizontal distance}}$ expressed as a fraction reduced to simplest terms.

■ 55. CONVERSION OF SLOPE EXPRESSION UNITS.—*a*. Unit degree, percent, and mil slopes are illustrated in figure 43. If arc and tangent are assumed to be equal, it is apparent that the relation may be expressed as follows:

$$\text{Degree: percent: mil: } \frac{1}{57.3} : \frac{1}{100} : \frac{1}{1{,}000}$$

or,

$$57.3° = 100 \text{ percent} = 1{,}000 \text{ mils}$$

Hence,

(1) $1° = 100/57.3 = 1.75$ percent, or
$1{,}000/57.3 = 17.5$ mils.

(2) 1 percent $= 57.3/100 = 0.57°$, or
$1{,}000/100 = 10$ mils.

(3) 1 mil $= 57.3/1{,}000 = 0.057°$, or
$100/1{,}000 = 0.1$ percent.

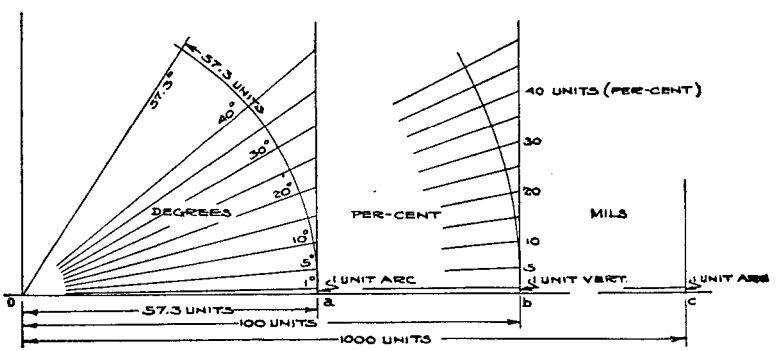

FIGURE 43.—Relation of units of slope.

b. The relations thus expressed, while suitable for conversion of angles up to 20°, are decreasingly accurate as the angle of slope increases, due to the fact that the assumption of equality of arc and tangent becomes increasingly erroneous as the angle increases. The amount of error inherent in this method of conversion for various slope angles is shown as follows:

Angle of slope		Actual percent of slope	Percent of slope computed by conversion factor
Degrees	Mils		
1	17.5	1.75	1.75
5	87.3	8.75	8.73
10	174.5	17.63	17.45
20	349	36.40	34.90
30	523.5	57.74	52.35
45	785	100.00	78.53
57.3	1,000	155.77	100.00

■ 56. AVERAGE SLOPES.—In determining slopes by the methods and formulas described, it should be remembered that the result expresses the slope of an inclined plane surface, whereas the actual surface of the intervening ground may vary quite irregularly up and down. It is therefore customary to refer to slopes thus determined between points over broken terrain or irregular surfaces as "average slopes."

■ 57. PROFILE.—The most satisfactory way of showing the slope of the ground is by making a profile. A profile is a cross section of a specific slope or hill cut by the intersection of the earth's surface by an imaginary vertical plane (fig. 38).

a. Profile from contoured map.—Figure 44① represents a portion of a contoured map. It is desired to construct the profile of the ground represented by the map between the points *A* and *B*. Proceed as follows:

(1) Connect the points *A* and *B* by a straight line and assume that a vertical plane is passed through the line *AB*.

(2) Use a piece of ruled paper which has parallel lines equally spaced; cut or fold the paper along one of these lines.

(3) Refer to the map and determine the highest and lowest elevation along the line *AB*; number the lines on the paper to correspond with the elevations on the map beginning with the highest elevation near the top edge of the paper (fig. 44②).

(4) Place the top edge of the paper along the line *AB* and, where the edge intersects each contour, drop a perpendicular to the horizontal line on the paper corresponding to the elevation of the contour being considered. Proceed in the same

manner with each contour. The profile is then formed by drawing a line between the points of intersection of the perpendiculars with the horizontal lines on the paper. Or, use another piece of paper having a straight edge. Place the straightedge along the line *AB* and make tick marks along the edge of the paper where it intersects each contour. Draw a vertical control line on the first piece of paper which has horizontal ruled lines. Move the paper with tick marks up

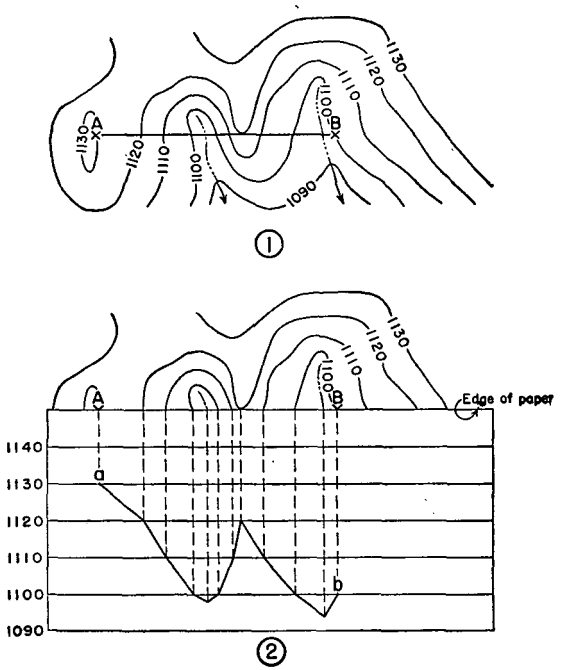

FIGURE 44.—Construction of profile.

and down the vertical control line, keeping the same tick mark on the control line. Place a point on each horizontal line where the tick mark with corresponding elevation intersects it. The profile is then formed by drawing a line between these points. The profile is then complete except between adjacent contours of the same elevation which require the determination of intermediate elevations.

(5) When the line crosses spurs or valleys, examine the map on both sides of the line, estimate the length of the crestline connecting the two adjacent contours and estimate the ratio of this line which lies on each side of the profile line. Compute the desired elevation, using the ratio of these two lengths to the contour interval. Where the line crosses a contour "circle" which forms a knob or depression, an elevation is sometimes found in this area which is of assistance in completing the profile.

(6) If a profile is desired of an irregular line on the map, such as a road or trench, divide the line into a series of sections approximately straight and plot as directed above, turning the paper at each angle to make a continuous profile.

b. Exaggeration.—For the purpose of clarity, profiles are usually exaggerated vertically in comparison with the horizontal, which for convenience is ordinarily the same as that of the map used (fig. 44②). Any selected horizontal or vertical scale may be used depending upon the material on hand and the information desired. In figure 44②, the horizontal profile lines represent 10-foot intervals; they could represent 5-foot intervals, thus further exaggerating the profile. The use of cross section paper will be found most convenient for constructing profiles, as the vertical lines aid in dropping perpendiculars to the horizontal lines.

■ 58. VISIBILITY.—A contoured map can be used to determine whether or not a point, a route of travel, or an area is visible from a given point. Because of inaccuracies inherent to map construction, it is unsafe to conclude that one given point can be seen from another given point if a profile, made from a map and between the points, shows the objective point to be only barely visible. One of the important uses made of maps by a military commander is to conceal lines of march or troop positions from an enemy's observation station. He and his staff officers are thus solving problems of visibility; by inspection of the shape, location, and elevation of map contours, they are determining approximately whether or not certain points can be seen from other points shown on the map. To be a successful troop leader, every officer and noncommissioned officer should be able to solve map visibility problems with reasonable accuracy and rapidity. Frequently the desired information can be obtained by inspection, but when

this is not possible some graphical or mathematical method should be used. The most common are the profile, similar triangle, and graphical methods. The profile method is more laborious than the others, but it is the best because of the completeness and clarity of its results, especially in determining visible areas. The similar triangle method can be used to abbreviate the profile method in many cases, especially in determining the visibility of points, short lines, and small

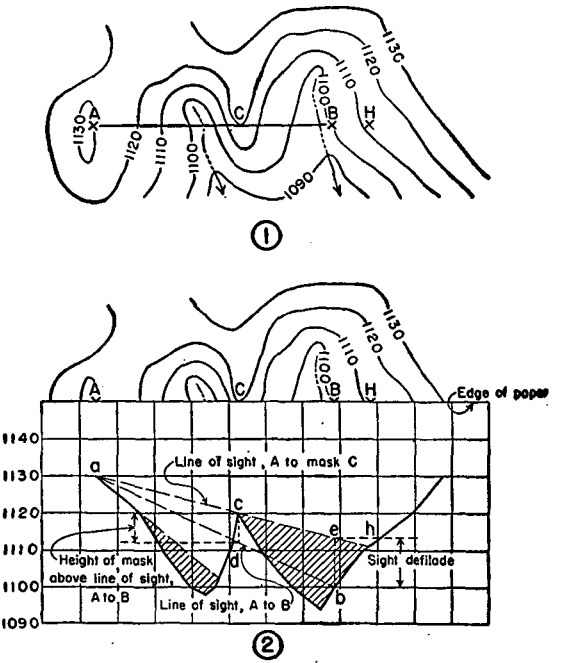

FIGURE 45.—Determination of visibility by profile method.

areas. The graphical method is convenient for checking up visibility along a line without drawing a profile. The extent to which visibility may be determined from a map depends upon the contour interval. The unrepresented variations in relief are of minor character if the contour interval is small. If the contour interval is large, unrepresented ground features may have an important influence.

a. Inspection method.—The following rules may be helpfully applied in determining by inspection the intervisibility of two points shown on a map:

(1) The points, if on opposite sides of a valley and located well above the intervening ground, are intervisible.

(2) If between two points there is a feature represented higher than both, they are not intervisible.

(3) If between the two points a feature is represented which is higher than one of the points, the points may or may not be intervisible.

(4) If the slope of the ground between the two points is convex, they are not intervisible.

(5) If the slope of the ground between the two points is concave, they are probably intervisible.

(6) When the ground between the two points is level, their intervisibility depends upon the presence of vegetation and works of man.

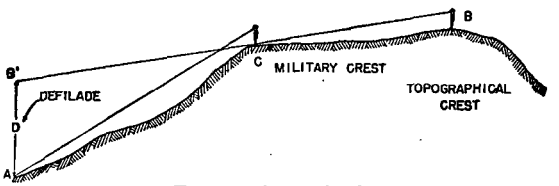

FIGURE 46.—Defilade.

b. Profile method.—(1) Figure 45① represents a portion of a contoured map. It is desired to determine whether or not *B* is visible from *A*. By use of cross section paper, construct a profile along the line *AB* as described in paragraph 57 (fig. 45②). Draw a line *ac* representing the line of sight from *A* tangent to the crest at *C*. This line strikes the ground at *h*. Therefore that portion of the ground between *C* and *H*, including *B*, is not visible from *A*.

(2) It may be noted that in the above example points *A* and *B* were both selected at ground level. Had it been desired to determine whether a man at *A*, eyes 5 feet above the ground, could see a truck 8 feet high at *B*, it would have been necessary to plot *a* in the profile (fig. 45②) with an elevation of 1,135 feet and *b* with an elevation of 1,108 feet. The result would be similar to that illustrated in figure 46. However the map reader will seldom be concerned with

the eye level of a man in a standing position. In combat the available map will probably be uncontoured or of such a scale that 5 feet would make little difference. Also the observer near combat operations will probably observe from as near ground level as possible.

c. Defilade.—In figure 46, *B* represents the topographical crest, that is, the highest crest of a hill; and *C* represents the military crest, that is, the highest crest from which the entire lower part of the hill can be observed. If an observer at *B* is unable to see an object at *A*, due to an intervening hill, spur, wood, or other terrain feature, the object at *A* is said to be "sight defiladed." The intervening defilading feature is called the "mask." In figure 46, the crest at *C* interferes with the view of the foreground from the top of the hill; thus the military crest forms a mask for the topographical crest. The amount which the foreground at *A* is defiladed is equal to the vertical distance *AB'* from *A* to the prolongation of the line "observer-mask." Thus in figure 45, the distance *be*, which scales 13 feet, represents the defilade at *B* caused by the mask *C* when viewed from *A*. The term "height of mask" means the height of a mask above the line of sight between two objects at that point. In figure 45, *cd*, which scales 8 feet, represents the height of mask. Defilade problems like visibility problems may also be solved by a number of graphical and analytical methods.

d. Hasty profile.—The elementary example of defilade above may be mentally expanded to cover many cases of visibility. In a war of movement and aerial observation, terrestrial or captive balloon observation, the consequent visibility problems tend to decrease in importance. The advanced map reader may make some type of hasty profile based on the method employed in figure 47 showing the observer at *A*.

e. Defiladed areas.—From any point as an origin, a line on a map can be extended in any given direction. A profile or partial profile of the terrain passed over by this line can be drawn. Such a profile makes it possible for us to ascertain just what portions of the terrain over which the line passes are visible and just what portions are not visible from the point from which our line was extended. Carrying this factor further and by making a number of profiles, each corresponding to one of a number of lines radiating from a given point, we are able to calculate just what portions (areas) of the

terrain are and are not visible from any given point. Suppose *X* (fig. 48①) represents the plotted location on a contoured map of an observation station. It is desired to determine the areas to the east of *X* that can be observed and the areas that are defiladed. To solve this problem, first draw from *X* a number of radiating lines such as *XY*, *XY*^{1}, *XY*^{2}, and *XY*^{5}, so that the lines cover or include as much of the area in front of *X* as is desired. Afterward, construct a profile corresponding to each of these lines. Three such profiles, *XY*, *XY*^{2}, and *XY*^{5}, are shown in figure 48②. Next, determine on the

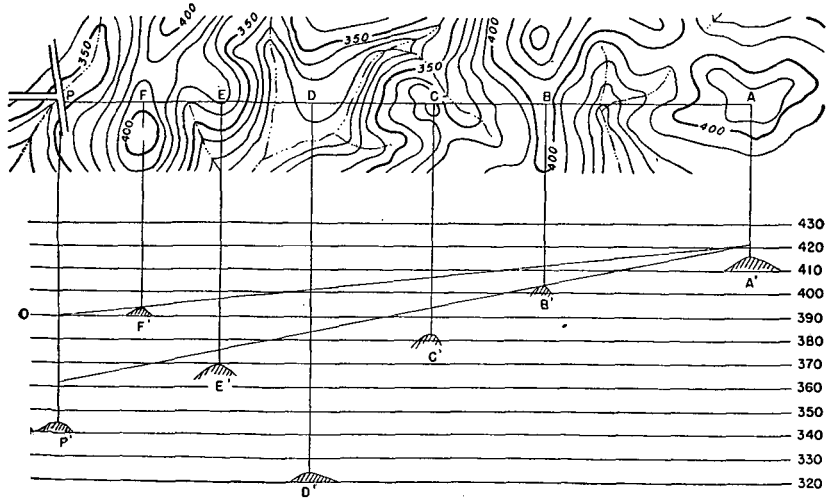

FIGURE 47.—Determination of visibility by hasty profile method.

profiles the parts of each that are defiladed. This may be done by simply drawing lines from *X* to the various crests indicated on the profiles; as in figure 48② *Y*, we see, by prolonging lines from *X* which just touch the tops of the various crests in front of *X*, that those parts of the line *XY* between *a* and *b* and between *e* and *f* are defiladed; similarly, in figure 48② *Y*^{2}, that $a^2 b^2$, $c^2 d^2$, and $e^2 f^2$ are defiladed; also in figure 48② *Y*^{5}, that $a^5 b^5$, $c^5 d^5$, and $e^5 f^5$ are defiladed. If, after solving a number of these profiles, we now plot on

our map the exact locations of the limiting points of the defiladed positions of each line and then afterward join these points as in figure 48①, we can connect up areas such as those shown by the shaded lines in figure 48①. It is then known that all shaded areas, such as those shown in this figure, are not visible from the observation point at *X*.

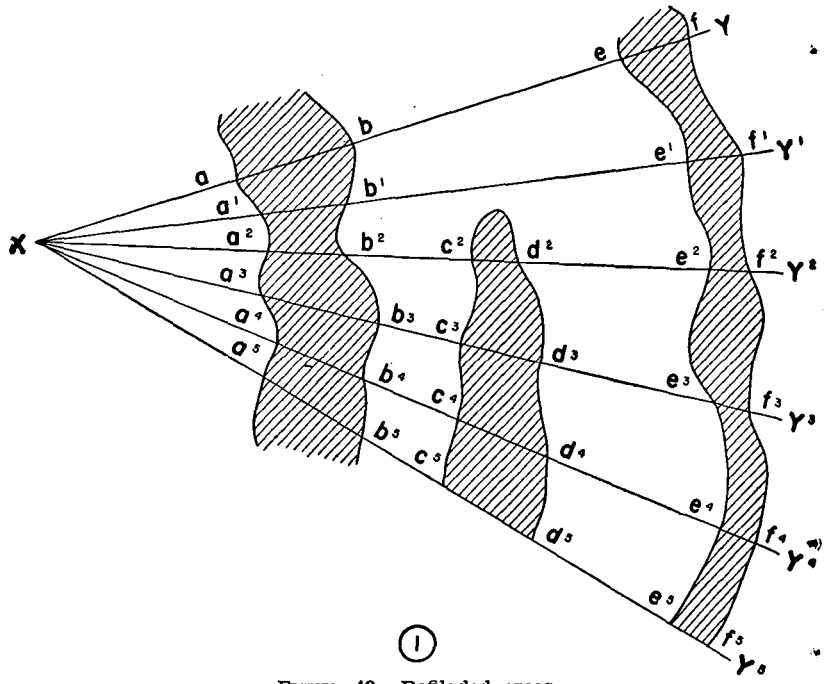

FIGURE 48.—Defiladed areas.

f. Foliage.—In solving problems of visibility, there often appears an intervening woods that may or may not interfere with the visibility. Any group of trees that may possibly defilade one object from another must be carefully considered.

■ 59. VISIBILITY DIAGRAMS (fig. 49).—Visibility diagrams indicate which portions of the ground are visible and which are invisible to an observer at some definite observation post. They

are also a practical aid in identifiying objects from an observation post when a good map is available. The determination by means of a map of the visibility of areas from a given point has been explained in paragraph 58, but personal reconnaissance is also necessary, because trees, hedges, and other objects not shown on the map may considerably affect the view. In constructing a visibility diagram, one should identify on the map the observation post and select a reference object. A line should be drawn joining the two and marked 0°. Lines are then set off at about 10° intervals on both sides of the

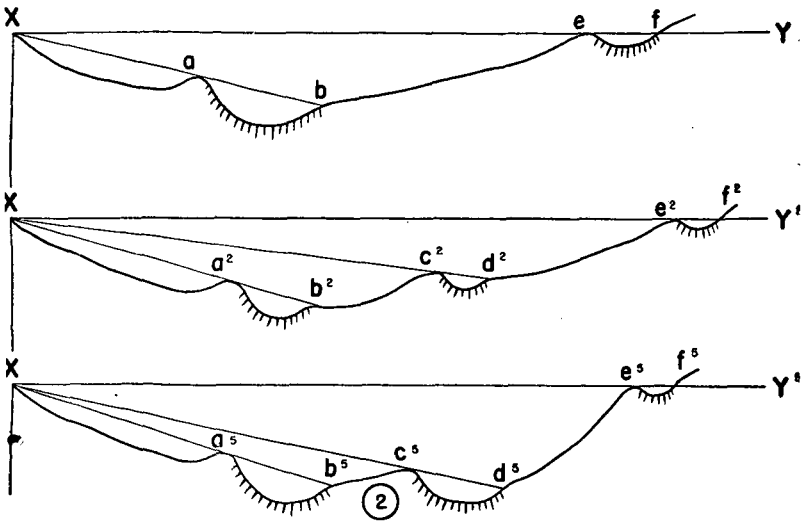

FIGURE 48.—Defiladed areas—Continued.

zero line radiating from the observation post. These serve as lines of sight to be investigated. Next study the features, mark on the map those which interfere with the view, and then determine those areas which are invisible from the observer's position.

■ 60. CURVATURE AND REFRACTION.—In computing intervisibility of points on a map by the methods described herein, the ground is assumed to be flat like the map and the light rays undeflected. Errors resulting from these assumptions are

negligible in average problems on local terrain. However, the earth is a spheroid, and distant light rays are bent from their path by passage through the atmosphere near the earth. The

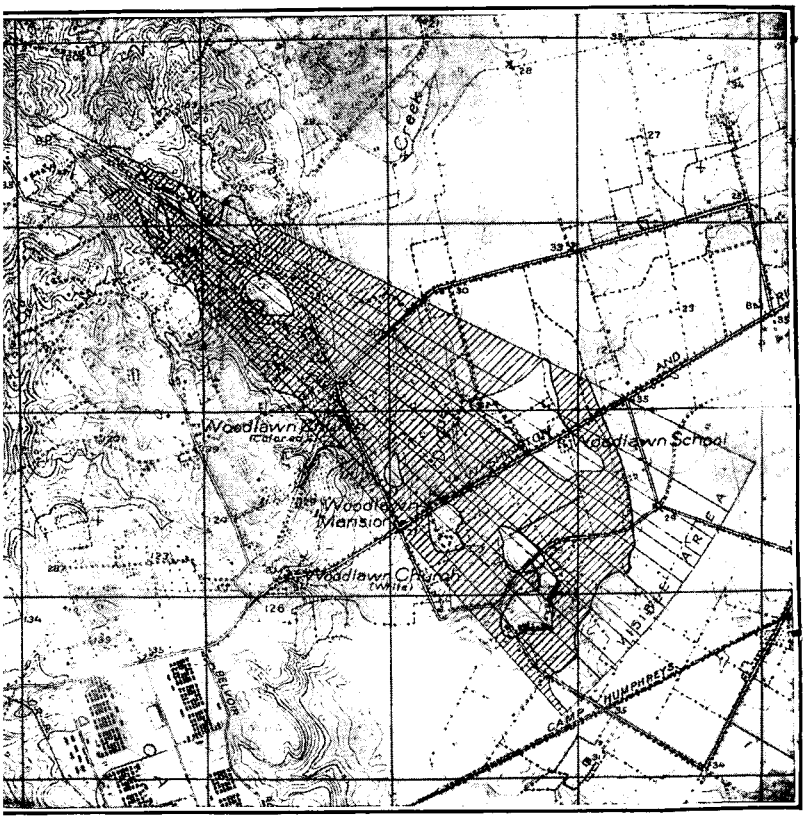

FIGURE 49.—Visibility diagram.

combined effects of curvature and refraction become appreciable at distances greater than 1 or 2 miles and should be duly considered when accurate results are desired.

SECTION VII

AERIAL PHOTOGRAPHS

■ **61. AERIAL PHOTOGRAPHS.**—*a.* An aerial photograph is a perspective picture, with either a vertical or an oblique viewpoint, taken from any kind of an aircraft. Except for color values and a certain capacity of the eyes to perceive differences in relief, the aerial photograph conveys the same impression in image as received by the human eye from the same viewpoint. Since the average person is unaccustomed to the vertical viewpoint, the images of familiar objects on photographs may at first appear strange and unassociated with the objects represented. The difficulties presented in interpretation of vertical aerial photographs appear to be no greater than those ordinarily encountered in learning to read conventional military maps and are overcome in the same way.

b. The vertical aerial photograph is a valuable instrument for conveying topographic information for the following reasons:

(1) It possesses in pictorial effect a wealth of detail which no map can equal.

(2) It possesses accuracy of form.

(3) With freedom of flight, an aerial photograph may be prepared in a short time.

(4) It may be reproduced in quantity by lithography.

(5) It may be made of an area otherwise inaccessible because of either physical or military reasons.

c. The vertical photograph is inferior to a map in respect to the following features:

(1) Important military features which are emphasized on a map are sometimes obscured or hidden by the other detail.

(2) Neither absolute position nor absolute elevation can be obtained.

(3) Relative relief is not readily apparent.

(4) Displacements of position caused by relief and camera tilt usually do not permit the accurate determination of either distance or direction.

(5) Because of a lack of contrast in tone, it is difficult to read in poor light.

(6) Marginal data furnished on maps are generally lacking.

d. A large portion of the area of the United States has never been mapped. Of the area mapped, a large percentage is considered inadequately mapped because of having been mapped more than 40 years ago or to scales unsuitable for military use. The preparation of military maps under service conditions involves factors of both time and space. In consequence, it may require a period of some length before a satisfactory map can be prepared covering territory which has not been adequately mapped. On the other hand, a film may be exposed in an aerial camera over either enemy or friendly territory, the negative developed, and the photograph printed in the course of a few hours. In consequence, the value of the aerial photograph as a means for supplying topographic information before maps can be made available, or before existing maps can be revised, is readily apparent. However, because of its limitations, the aerial photograph does not constitute an ideal map, and its best use is either as a map substitute or as a map supplement. The ideal situation would include the availability of the most accurate topographic map possible, supplemented by the most recent aerial photographs.

■ 62. TYPES OF AERIAL PHOTOGRAPHS.—*a.* Aerial photographs used for military purposes are made with the Air Corps cameras listed in the following table:

TABLE IV.—*Characteristics of photographs made with U. S. Army Air Corps cameras*

Camera	Focal length in inches	Photograph size in inches	Width covered by single photograph in miles at scales of—			Flying altitudes in feet for scales of—			Flight line spacing in miles to give an overlap equivalent to 50-percent overlap on 7- x 9-inch photograph			Purpose
			1:10,000	1:20,000	1:40,000	1:10,000	1:20,000	1:40,000	1:10,000	1:20,000	1:40,000	
K-3B	8.25	7 x 9 or 9 x 9	1.42	2.84	5.68	6,875	13,750	[1] 27,500	0.71	1.42	2.84	A fully automatic aircraft camera for reconnaissance, photographic mapping, and spotting missions.
K-3B	12	7 x 9 or 9 x 9	1.42	2.84	5.68	10,000	20,000	[1] 40,000	.71	1.42	2.84	Do.
K-7C	24	9 x 18	2.84	5.68	11.36	20,000	[1] 40,000	[1] 80,000	1.42	2.84	5.68	An aircraft camera for high altitude, large-scale, spotting and reconnaissance mapping.
K-12	13.5	8 x 10	1.58	3.6	6.32	11,250	22,500	[1] 45,000	0.79	1.58	3.16	An aircraft camera, single lens, with between-lens shutter to take aerial photographs at night.

[1] Impractical flying altitudes due to airplane limits or bumpy air.

TABLE IV.—*Characteristics of photographs made with U. S. Army Air Corps cameras*—Continued

Camera	Focal length in inches	Photograph size in inches	Width covered by single photograph in miles at scales of—			Flying altitudes in feet for scales of—			Flight line spacing in miles to give an overlap equivalent to 50-percent overlap on 7-x 9-inch photograph			Purpose
			1:10,000	1:20,000	1:40,000	1:10,000	1:20,000	1:40,000	1:10,000	1:20,000	1:40,000	
T-3A (five lens).	5.9	Center, 5.4 x 5.4; composite, 32 x 32, approximately.	5.1	10.2	20.4	4,920	9,840	19,680	4.05	8.11	16.22	An aircraft five-lens camera covering a total included angle of 140° for tactical reconnaissance, mapping survey, and rough mosaics.
T-5	6	9 x 9	1.42	2.84	5.68	5,000	10,000	20,000	0.71	1.42	2.84	An aircraft camera designed for precise topographic surveying and to be used with photogrammetric equipment.

b. The photographs made with the cameras listed in *a* above are classified as follows:

(1) *Plain verticals* (fig 50).—(*a*) The term "plain vertical photograph" is applied to all those obtained by pointing a single-lens camera at time of exposure so that the optical axis is as nearly vertical as possible. Plain verticals are made with Air Corps K-type cameras. Since the camera film is practically horizontal, features on the ground are registered on a vertical photograph in perspective with little or no distortion in

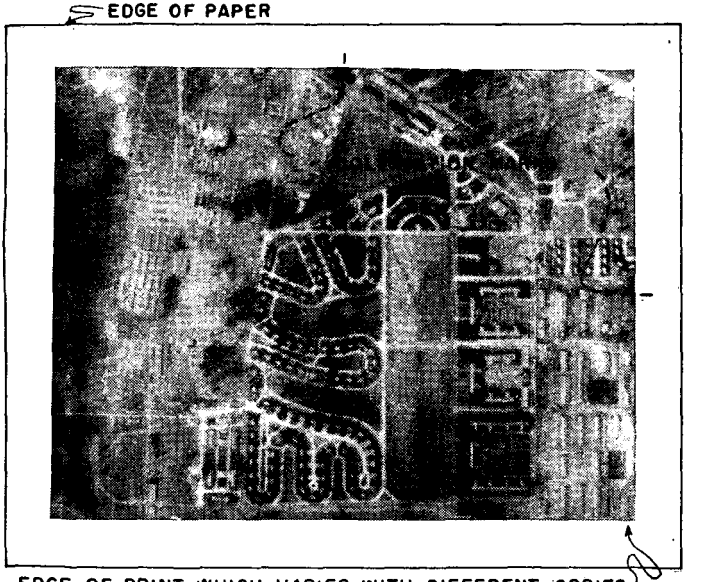

FIGURE 50.—Plain vertical made with Air Corps K-type camera.

their relative shapes and sizes. This is the most useful type of photograph for general military purposes and is the one commonly referred to as an aerial photograph.

(*b*) The neat lines as shown on the vertical in figure 50 are not always the same on photographs made from the same negative. In order to facilitate accurate location of points on vertical photographs, ticks or collimation marks are registered in the center of the four sides of the negative at the time

of exposure by means of a templet in the camera. The method of measuring from these collimation marks is given in paragraph 104*b*.

(2) *Obliques.*—Oblique aerial photographs are obtained by intentionally tilting the optical axis of the camera from the vertical. The oblique photograph is a rectangle, while the area of ground photographed is a trapezoid (fig. 51).
In making obliques the optical axis of the camera is usually held inclined about 30° to the horizontal (fig. 51) at a comparatively low altitude and such obliques are termed "low obliques." Those exposed so as to include the image of the

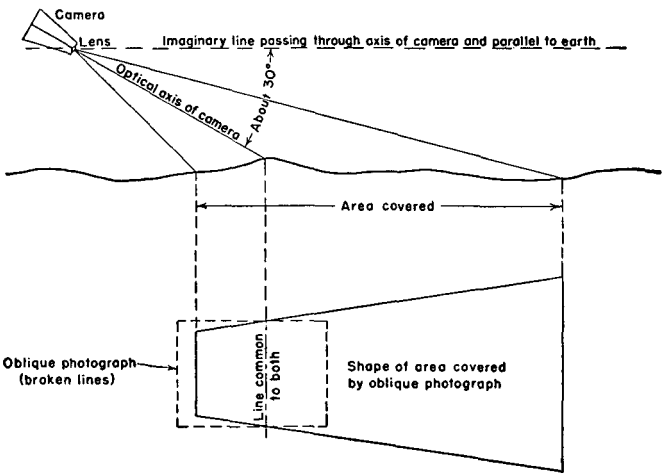

FIGURE 51.—Relative shape of area covered by oblique photograph compared to photograph itself.

horizon are termed "high obliques." Obliques are useful in emphasizing ground forms, in studying vertical dimensions of terrain features or works of man, or in interpreting detail not easily distinguished on vertical photographs when the clarity of perspective is desirable. Obliques cannot be accurately scaled. An oblique may be regarded as a highly improved and economical substitute for a panoramic sketch.

(3) *Composites.*—A composite photograph is one made by joining several photographs transformed to a common plane which have been taken at a single-camera position. Vertical

composites are made with the Air Corps T–3A type multiple-lens camera. This camera has one central chamber, the optical axis of which is held in a vertical position at exposure, and four peripheral chambers, the lenses of which

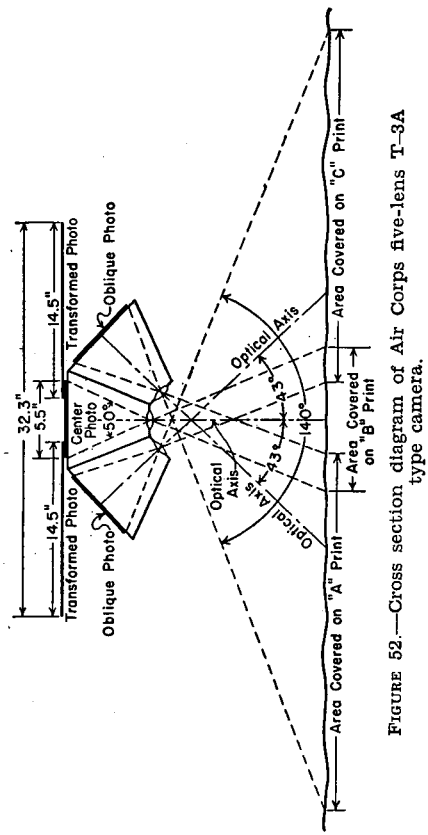

FIGURE 52.—Cross section diagram of Air Corps five-lens T–3A type camera.

are inclined at an angle of 43° with the central lens (fig. 52). The camera has a focal length of 150 millimeters (approximately 6 inches). The result of a single exposure with this camera is one plain vertical photograph which trims to 5.4 by 5.4 inches and four obliques (called wing photographs)

which are transformed to the plane of the center photograph, joined to it, and mounted to produce a single photograph in the shape of a Maltese cross approximately 32 by 32 inches (fig. 53). The transformation of the wing photographs to the plane of the center photograph is effected by means of a transforming printer which projects the wing negatives

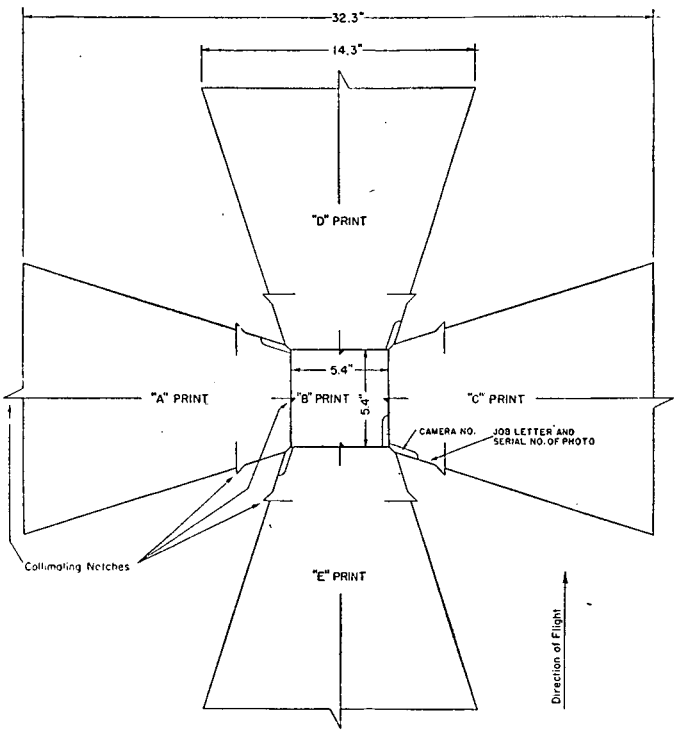

FIGURE 53.—Diagram of composite photograph made with Air Corps five-lens T-3A type camera.

to print paper which is inclined at an angle corresponding to the lens inclination in the T-3A camera (fig. 91). The term "contact prints" applies to photographs made from negatives before their transformation. Thus the contact prints of all five chambers of the T-3A camera measure 5.5

by 5.5 inches. Due to the wide angular scope of 140° and the short focal length of the T–3A camera, a single photograph from a relatively low altitude will cover an area of great width. For example, a single picture at 18,000 feet altitude gives a picture approximately 18 by 18 miles in dimension. It is this feature which makes this camera particularly adaptable to military mapping and to exploiting the detail of a large expanse of terrain from a single photograph. It has also been found possible to make a nine-lens composite (fig. 93) by taking two pictures with T–3A cameras with the vertical axis of the pictures skewed at 45° in respect to one another, thus using the wing photographs of one composite to fill the voids of the other. A photograph of a large area can be produced much more quickly by this method than by the construction of a mosaic.

■ 63. PIN POINTS.—Two or more stereoscopic photographs of an isolated object or spot constitute a pin point. Airdromes, supply depots, dumps, road crossings, bridges, or other bottlenecks on lines of communication requiring detailed study are suitable objects for pin point photographs.

■ 64. STRIPS (fig. 54).—Successive overlapping photographs made from an airplane flying a selected course line or direction constitute a photographic strip. Vertical photographs are usually taken in such strips with a constant overlap of approximately 60 percent between successive pictures forming the strip. A strip made in order to secure information regarding the condition of, or activity along, a more or less extended but narrow section of terrain, such as along a road, a railroad, a stream, an avenue of approach, a zone of action, or a stabilized front line, is called a "reconnaissance strip." When the several photographs of a single strip are joined together or mounted to form a mosaic, the result is a "strip mosaic." Strip mosaics may be either controlled or uncontrolled.

■ 65. MOSAICS.—*a. Uncontrolled mosaic.*—A mosaic is formed by joining several overlapping vertical photographs taken at different camera positions. When several photographs are oriented by matching the detail along their borders, the result is an "uncontrolled mosaic," which gives a good pictorial effect of the ground but will contain serious errors of scale

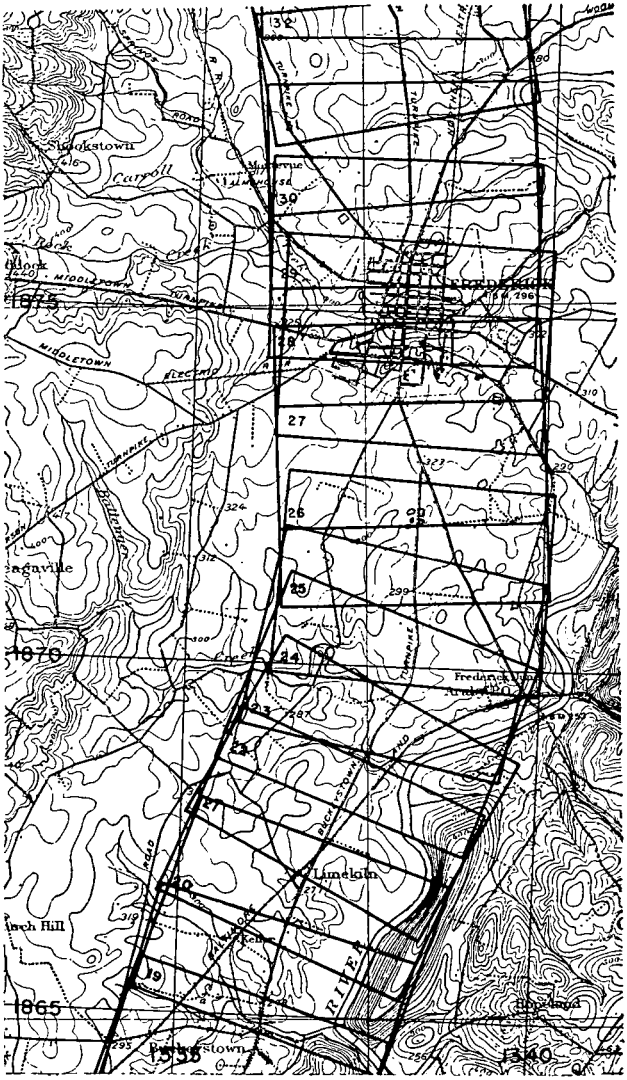

FIGURE 54.—Section of index map showing strip of K-type aerial photographs plotted on map of 1: 62,500 scale.

and azimuth. While care in matching the photographs will assist in approaching accuracy, the only way that scale accuracy can be obtained is by having recognizable control on the ground.

b. Controlled mosaics.—By adjustment of vertical photographs to plotted portions of ground control points and by various other modifications of the photographs as obtained directly from the camera, errors of scale and direction inherent to single photographs and uncontrolled mosaics may be greatly reduced. If the individual prints are prepared by contact printing directly from the aerial camera negatives, they may vary considerably in over-all or average scale due to changes in plane altitude and ground elevation between successive photographs. In the preparation of controlled mosaics from such prints it is customary to determine the average scale of all the photographs by reference to ground control data and to assemble the mosaic on a control plot prepared at that scale. The technique of this operation is described in paragraph 101, TM 5–230. The variation in scale of the individual prints from the average scale of all the prints used, as well as local scale errors caused by camera tilt, will result in mismatching of detail where the prints are joined. The controlled mosaic, therefore, is frequently less pleasing in appearance than the uncontrolled mosaic; however, it is much more reliable for the measurement of distances and direction. If equipment and time are available the individual prints may be reduced or enlarged to the same scale and, in addition, the tilt errors partially or completely removed. These processes are referred to as ratioing and rectifying. If sufficient data as to ground elevation are available, local scale errors caused by variation of ground elevation within the scope of each individual print may be reduced by rephotographing each print in two or more sections. This process is called "pyramiding." Mosaics which are prepared from ratioed, rectified, and pyramided prints approach the accuracy of the best maps in representation of distances and directions. Because of the time involved in these processes as well as the necessity of obtaining extensive ground control data, the highly accurate controlled mosaic will seldom be encountered during initial stages of combat.

■ 66. PRINT PAPER.—Photographs may be printed on either glossy, matte, or semimatte paper of single or double weight. Unfortunately print paper shrinks in the processes of development, sometimes to a most disconcerting extent. Glossy paper gives clearest definition of detail but will receive marks or notations only in ink. Light matte paper shrinks badly and lacks sharpness of detail but will receive either pencil or ink marks. Doubleweight semimatte paper of best quality has low shrinkage, will receive pencil marks, may be used unmounted, and has clearer definition of detail than matte paper of the same weight. Changes in temperature and moisture cause glazed print paper to curl up and become refractory. In general, all prints intended for extensive use should be mounted on manila or similar paper with rubber cement. Photographs used on mapping projects are mounted on heavy cardboard or on thin metal sheets in order to reduce their shrinkage.

■ 67. PICTURE POINTS.—In studying one or more aerial photographs it is sometimes desirable that one be able to identify readily selected points of detail. Points thus chosen are marked on the photographs by small circles about 0.2 inch in diameter. They are known as "picture points." By marking points in this manner adjacent detail is not obscured.

■ 68. OVERLAYS.—Not only is it difficult to mark on the face of a glossy photograph, but marks on the face of any photograph tend to clutter it up, obscure important detail, and diminish its usefulness. Yet it is sometimes desirable that positions of objects be emphasized or that military information such as that representing the disposition of troops, organization of ground, enemy or friendly works, supply and circulation activities, and other information shown graphically on special military maps be recorded by some means without unnecessarily damaging the print. This has been satisfactorily solved by means of overlays of high-transparency paper. A light, tough, almost colorless tracing vellum is most suitable for this work, yet any kind of transparent tracing paper which will take pencil and ink marks will answer the purpose. The tracing should be cut to fit the photograph and then carefully registered to the photograph (fig. 55). This may be done by tracing in the neat line in full or only

at the four corners, by tracing in the border ticks and the center cross, or by any convenient combination of these. The serial number of the photograph should always be traced in. Significant marginal information on the photograph should also appear on the margin of the overlay as far as consistent. The overlay should be fastened to the photograph along one edge by a little mucilage or, better still, by means of two ordinary paper clips. This will enable the overlay to be lifted at one edge for direct examination of detail without disturbing the relation of the overlay to photograph. (All

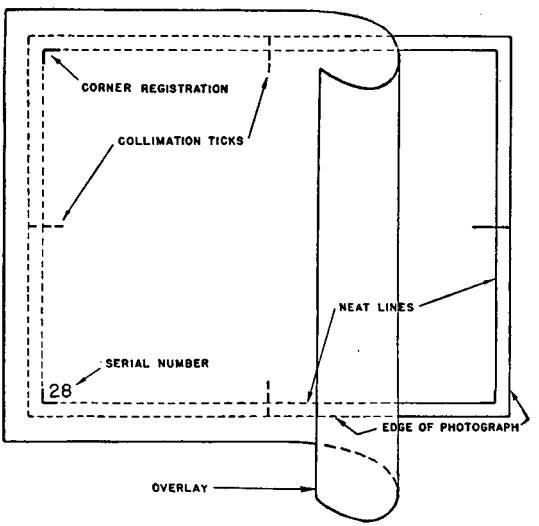

FIGURE 55.—Registered overlay.

photographs destined for extensive use should first be mounted with rubber cement on a sheet of stiff manila or similar paper cut slightly larger than the photograph and the overlay tacked to the mount as described above.)

■ 69. CONVERSION TO LINE MAP.—*a. Methods.*—It is sometimes desirable to convert a photograph to a line map. By doing so, unnecessary detail can be eliminated on the one hand and on the other hand important military features can be emphasized through their representation by conventional map symbols.

This can be done in two ways: either by tracing on a sheet of transparent overlay the topographical detail desired, or by bleaching the photograph. The latter method is seldom used.

b. Tracings.—A tracing of the detail of a good vertical photograph of average terrain in which the features are represented by map symbols in the conventional way and supplemented by useful marginal information, such as the magnetic north point and scale, becomes for practical military purposes an uncontoured map of the area photographed at the scale of the photograph. In this way every detail on the face of a photograph is preserved unblemished and yet the information recorded stands out emphatically. The original tracing may be used as a map or the tracing may be used to reproduce the map in quantity by any of the authorized reproduction processes.

■ 70. To Index and Plot.—On receipt of one or more photographs of an area of which some sort of a map is available, examination and study of the photographs are facilitated by first outlining on the map the area or areas covered by the photograph or photographs as indicated in figure 54. This is best done by determining the scale of the photographs and using the relation to scale of map to construct a templet of tracing paper or other suitable transparent material which represents the dimensions of the photograph to the scale of the map. Thus a templet outlining the ground covered in a photograph having a scope of 7,000 by 9,000 feet on a map having an RF of 1: 20,000 would measure

$$\frac{7{,}000\times 12}{20{,}000} \text{ by } \frac{9{,}000\times 12}{20{,}000} \text{ or } 4.2 \text{ by } 5.4 \text{ inches.}$$

If transparent material is not available, the templet may be made from opaque material by constructing a frame inclosing a cut-out area having the scope of the photograph to the scale of the map. The templet is placed on the map and shifted about until its outline includes the details shown on the photograph. The area covered on the map is then outlined by marking around the templet. The serial number of the photograph is entered in the outline. The process is repeated for any number of photographs in hand. The result is an index sheet of the photographs showing com-

prehensively the relation of the photographs to one another and to the area.

■ 71. CARE OF AERIAL PHOTOGRAPHS.—Unmounted aerial photographs should always be filed flat and kept weighted down when exposed to changes in temperature. Never place them near a radiator, stove, or other heating device, as the photographs will curl up tightly and set in that shape. Never roll up the photographs for any purpose. When in the field, protect them from moisture as much as practicable. A heavy manila envelope is suitable for this purpose and is a convenient container.

■ 72. SOURCES OF ERROR.—Were it possible to photograph an area of perfectly flat terrain from a perfectly level plat-

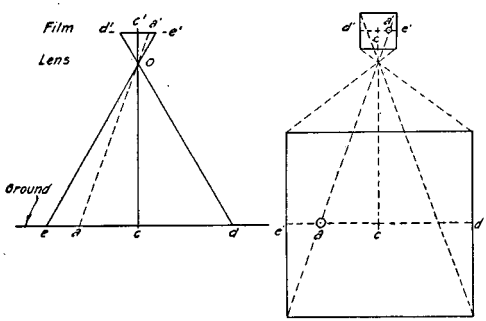

FIGURE 56.—Relation of image on photograph to object on ground under ideal conditions of level ground and camera.

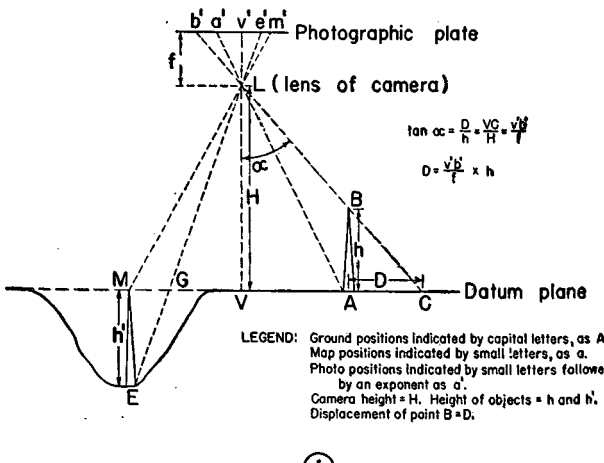
form at a desired elevation, the result would be a perfect map in all planimetric detail, assuming the camera registered a true image. This may be verified by examination of figure 56. Any image *a'* would appear on the negative in the same relation to all other images on the photograph as the object *a* on the ground bears to all other objects on the ground, and similar relation would obtain between the lines *d'e' and de.* The ground is seldom, if ever, perfectly level, and it is impracticable to fly an airplane continuously in any selected horizontal plane. Air currents and variations of air density cause the airplane to tilt about either axis and rise and fall in elevation. Distortions are also caused

by the camera lens, the shutter speed in a rapidly moving airplane, the roughness of the film, the departure of the film from the focal plane (warping of the film), and temperature and moisture changes of the film and the print paper, which may result in errors in the photographic record of the terrain. By careful photography, with good instruments and good materials at elevations of 5,000 feet or higher, all errors of sources other than tilt and relief may be neglected in practical military uses of aerial photographs. At elevations lower than 5,000 feet the aggregate effect of such errors may be very material.



①

FIGURE 57.—Diagram showing displacement of position on aerial photographs caused by relief.

■ 73. EFFECT OF RELIEF.—*a.* In making a map, all topographic detail is in effect projected vertically upon a horizontal plane. This results in such detail being relatively correctly located so as to permit accurate measurements of direction and distance. Reference to figure 56 will indicate that only one point *c* is projected vertically from the earth to the photograph. The remainder of the photograph is a conic rather than a vertical projection. The effect of such a conic projection is illustrated in figure 57①. In this figure, *L* represents a camera lens with

the negative of a plain vertical photograph the focal distance f above it. The line LV is vertical to the earth at point V, therefore the image of V or v' is called the plumb point of

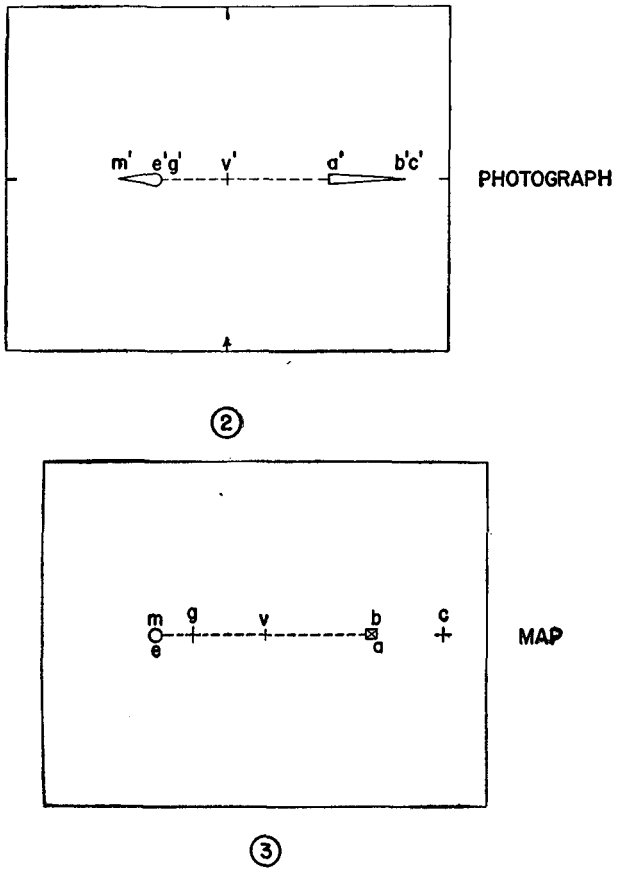


FIGURE 57.—Diagram showing displacement of position on aerial photographs caused by relief—Continued.

the negative. Since in this case the optical axis of the camera is assumed to be held truly vertical, v' is also the principal point of the negative as well as the plumb point. The dis-

tance *LV* is equal to the height of the camera lens above the ground and is designated *H*. If we consider the monument *AB* having its base in the datum plane passing through the point *V* and having a height of *h*, it is apparent from the rays of the camera, indicated by broken lines, that whereas the base of the monument point *A* will appear at *a'* on the negative, the top point *B* will appear at *b'* or in the same position on the negative that the point *C* in the datum plane of *V* would appear. The apparent displacement of *B* is in consequence the distance *D*. The displacement on the negative is the distance *a'b'* and is outward from the plumb point *v'*. In the same figure it may be observed that the image of the point *E*, which is below the datum plane passing through the point *V*, is displaced inward toward *v'* to *e'*. Errors due to relief are present to some extent in all photographs of natural terrain. They cannot be eliminated by rephotographic processes and remain present in all reductions, enlargements, or transformations. In figure 57② is shown in full scale the resulting photograph of the objects shown in figure 57①, and in figure 57③, for the purpose of comparison, their vertical projection as they would be represented upon a map.

b. In figure 57① the triangles *LVC*, *BAC*, and *Lv'b'* are similar right triangles. Consequently the following equations obtain:

$$\tan \alpha = \frac{VC}{H} = \frac{D}{h} = \frac{v'b'}{f} \qquad (1)$$

Therefore

$$D = h \tan \alpha \qquad (2)$$

and

$$D = h\frac{v'b'}{f} \qquad (3)$$

c. From the above discussion it is apparent that—

(1) All displacements due to the elevation of a point above or below the datum plane are radial from the plumb point *v'*.

(2) Since tan α increases as the horizontal distance of the observed point from the point *V* increases, from equation (2), we know that displacements are greater at the outer edges of the photograph.

(3) Similarly since tan α increases as the elevation of the camera above the ground decreases, from equation (2), we know that displacements increase as the camera lens height *H* is decreased. For this reason it is usual when photographs

are to be used as a map to photograph terrain of average relief from heights of not less than 10,000 feet.

(4) Since in figure 57① displacements are radial from the plumb point v', the directions of only those lines which pass through that point can be accurately measured. Errors in

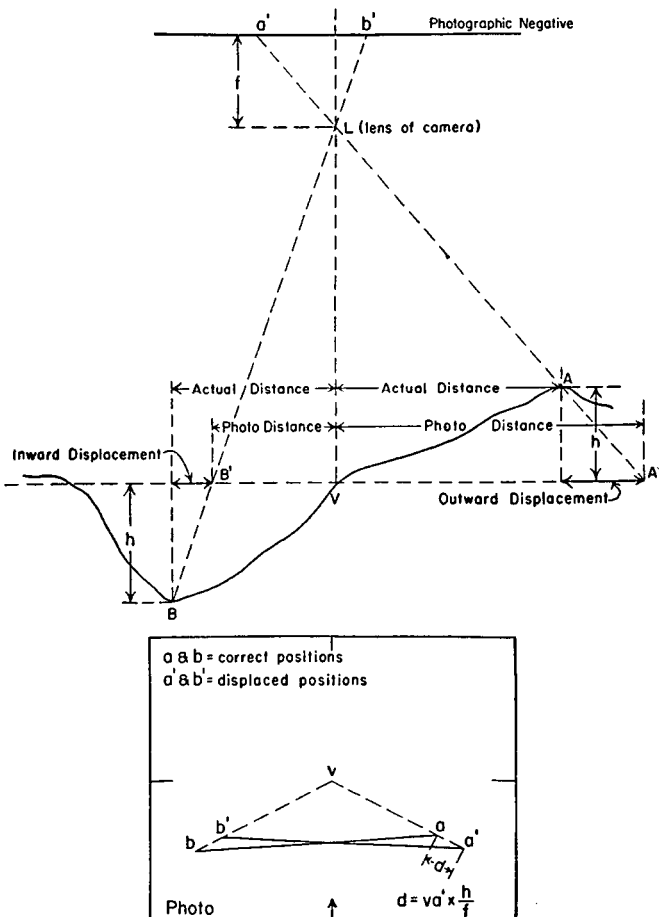

FIGURE 58.—Diagram showing errors in direction caused by relief.

the direction of other lines on the photograph can be caused by relief as illustrated in figure 58. The points *A* and *B* shown in this figure in profile are shown on the photograph (not to scale) displaced to *a'* and *b'*, respectively, because of relief, their true positions being plotted at *a* and *b*, respec-

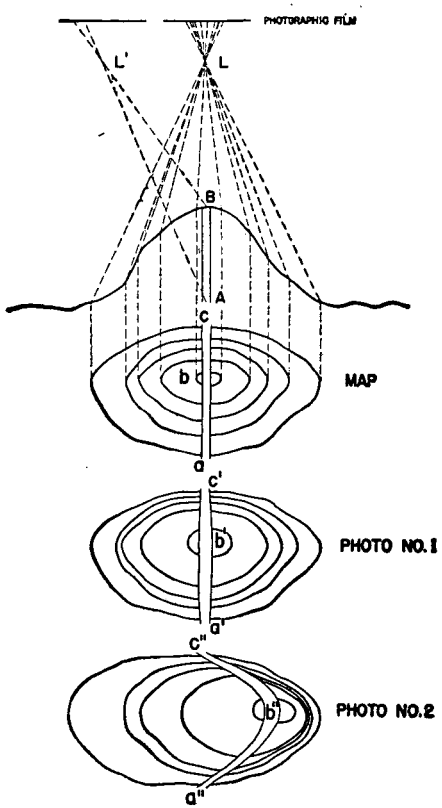

FIGURE 59.—Diagram showing effect of relief upon scale.

tively. The direction line between *A* and *B* (or *ab*) is therefore incorrectly shown on the photograph as *a'b'*.

(5) In figure 57① while *h* equals *h'* and *MV* equals *VA*, *e'm'* does not equal *a'b'*. It can therefore be stated that the scale

of all parts of a photograph of terrain having relief will not be the same. Those objects or features on high ground will be shown at a larger scale than those on lower ground. This is illustrated in figure 59 which shows the appearances of a hill when represented by a vertical projection on a map (Map), when photographed from directly above (Photo No. 1) and when photographed from a point to one side (Photo No. 2). The lens positions L and L' may be considered to be consecutive positions and the hill to appear in the overlap of the two pictures of the same strip. The difference in the appearance of the road *ca* is shown. Obviously such images in the overlap of successive photographs cannot be "matched" successfully as, for example, in the preparation of a mosaic. Since the images of two objects in the overlap area of successive photographs of rolling country are displaced in different degree and almost opposite direction, two photographs of such terrain cannot be accurately oriented by merely matching detail.

d. Since the distance $v'b'$ (fig. 57①) and f (the focal length of the camera) are known or measurable, the actual displacement of an object such as point B in figure 57① may be determined from formula (3), *b* above, when its height h above the datum plane passing through the point V is known.

■ 74. EFFECT OF TILT.—*a*. Because of the instability of an airplane, so far no means have been discovered of maintaining the camera in a truly vertical position at the instant of exposure. Level bubbles are used to indicate the tilt of the camera both in the direction of flight (sometimes defined as tip) and in the transverse direction. However, the bubbles are affected by centrifugal force as well as by gravity when the airplane is skidding, and their reactions are too slow to record sudden deviations from the horizontal. The effect of tilt is illustrated in figure 60. In this figure a section of theoretically level terrain is represented as being photographed with a camera having its lens position at L. The camera, instead of being truly vertical with its axis as the line vLV and the negative in a horizontal position, is tilted about L by an amount equal to the angle θ, and the camera axis takes the position $p'LP$. The principal or center point of the tilted negative is p'. The line from the lens vertical to the ground LV when extended upward intersects the tilted negative at

v', the plumb point. The plumb point of the untilted negative *v* is also its principal or center point. The plane of the tilted negative passes through the plane of the untilted negative along a trace called the "axis of tilt." The middle point of the axis of tilt, point *i'*, is called the "isocenter." Since both *Lp' and Lv* equal the focal length of the camera, triangles *Lp'i'* and *Lvi'* are similar right triangles. If the angle θ is a small angle, *i'v* may be said to equal *i'v'* in length. Consequently *p'i* is equal to *i'v'* and the isocenter *i'* is midway between the plumb point *v'* and the principal point *p'*. Assume that points *A* and *B* are points on the ground forming two of the four corners of a rectangle. Their images appear on the tilted negative at *a'* and *b'*, respectively, and on the untilted negative at *a* and *b*, respectively. On the depressed side of the negative the image of the point *A* is displaced inwardly to *a'* along a line passing through the isocenter *i'*. On the elevated side of the negative the image of the point *B* is displaced outwardly along a line passing through the isocenter *i'*. Thus the area *abcd* registered on the untilted negative as a rectangle is registered on the tilted negative as the trapezoid *a'b'c'd'*. It may be noted that the axis of tilt is common to both the tilted and the untilted negatives. It is the line of unchanged scale on the tilted negative. It is obvious that as the angle of tilt θ decreases, points *p'*, *i'*, and *v'* approach coincidence. When the tlit is slight the distances *p'i' and v'i'* become inappreciable at the scale of the negative. This same relation holds true for the corresponding photograph which is shown by a broken line at the same focal distance below the lens *L*. However, in the photograph the point *A* would be registered on the elevated side, for which the angle of tilt θ is given a positive (+) value. On the other side of the photograph the tilt would be considered negative in sign.

b. It is also to be observed that the angles at *i'* formed by the lines radiating from *i'* to *a*, *b*, *c*, and *d*, respectively, remain unchanged by tilt. The scale of a tilted negative decreases progressively from *i'* outwardly in the direction of tilt on the depressed side and increases progressively outwardly in the direction of tilt on the elevated side. Therefore, lines parallel to the axis of tilt are lines of uniform scale but the scales of no two such lines are the same. For the

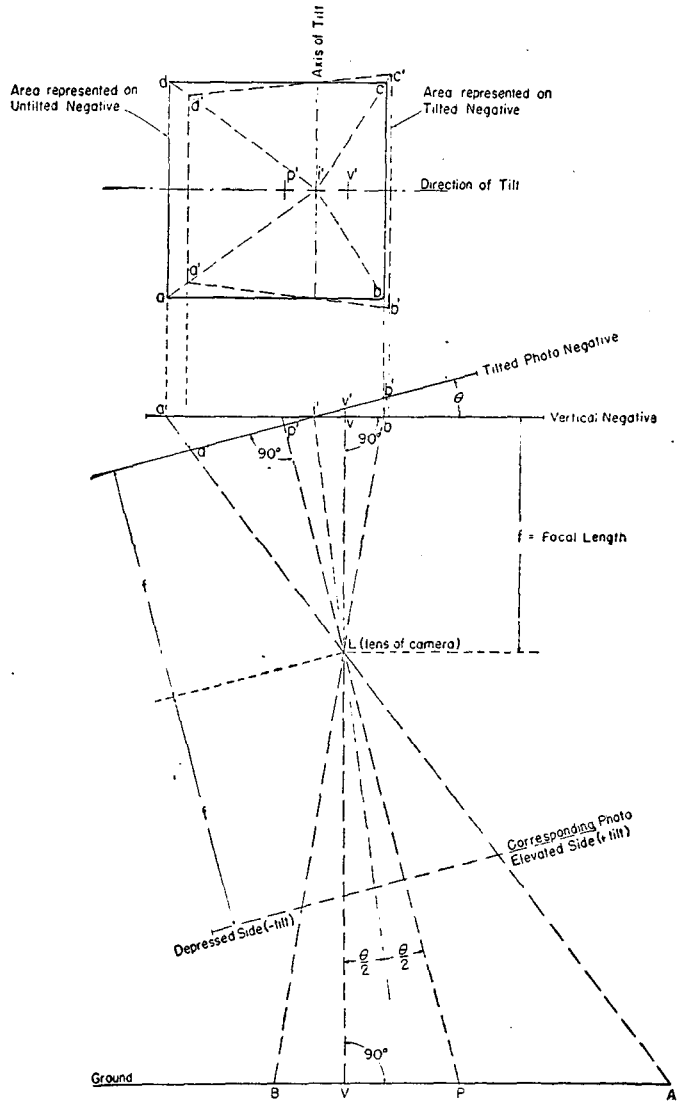

FIGURE 60.—Diagram showing effect of tilt.

same reason diagonal lines joining points unequally distant from *i'* are not lines of uniform scale and do not represent true direction.

c. The displacement due to tilt of casual points and directions is illustrated in figure 61. The images of the ground points *W*, *X*, *Y*, and *Z* are registered at *w'*, *x'*, *y'*, and *z'*, respectively, on the tilted photograph negative, whereas the correct positions of the points would have been shown on an untilted photograph at *w*, *x*, *y*, and *z*, respectively. The displacements of position and direction are apparent.

■ 75. COMBINED EFFECT OF RELIEF AND TILT.—Many puzzling discrepancies are sometimes found on close examination between the map and the vertical photograph, but when understood they will rarely present insuperable difficulties to the map and photograph reader. It has been seen that taken separately the effects of tilt and relief follow simple rules. However, it is their combined effect which is the cause of errors appearing on aerial photographs. These may be cumulative (fig. 62) or may be compensating. The displacements due to relief are radial along a line passing through the plumb point, and those due to tilt are radial along a line passing through the isocenter. The correction of the combined effect is simplified, however, in that these two points approach coincidence at the principal or center point of the photograph with decrease in the angle of tilt. It is therefore possible to assume in the case of slightly tilted photographs that for all practical purposes both displacements are radial along a line passing through the principal or center point. This assumption is made use of in the radial line method of restitution explained in paragraph 113. It does not obtain when the amount of tilt exceeds 3°. However, extensive tests have indicated that few photographs made by experienced aviators in favorable weather are tilted in excess of 3° and that the majority of the photographs are tilted less than 1°. In plain vertical photographs of average tilt taken over gently rolling or fairly flat terrain, the combined effect of errors of relief and tilt over the center half is negligible for ordinary use as a map substitute (precise measurements excepted) and is rarely prohibitive in the marginal portion. Such photographs if tilted in excess of 5° or containing a relief range in excess of 500 feet are

unsuitable for general use as contemplated herein because distances and angles measured on the photograph, as is ordinarily done on a map, will be appreciably inaccurate.

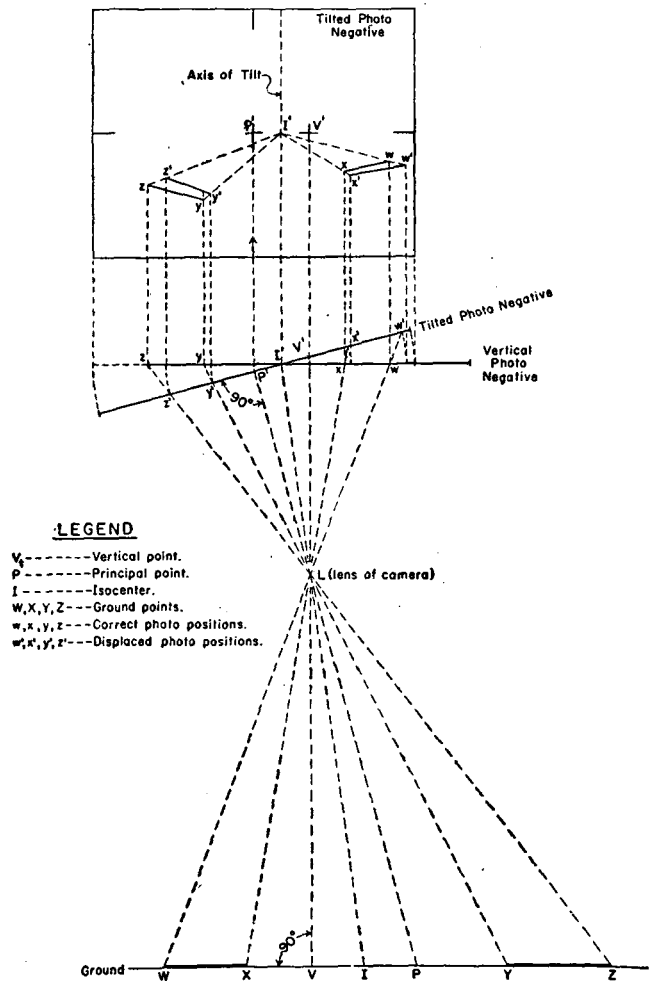

FIGURE 61.—Diagram showing displacement of position on aerial photographs caused by tilt.

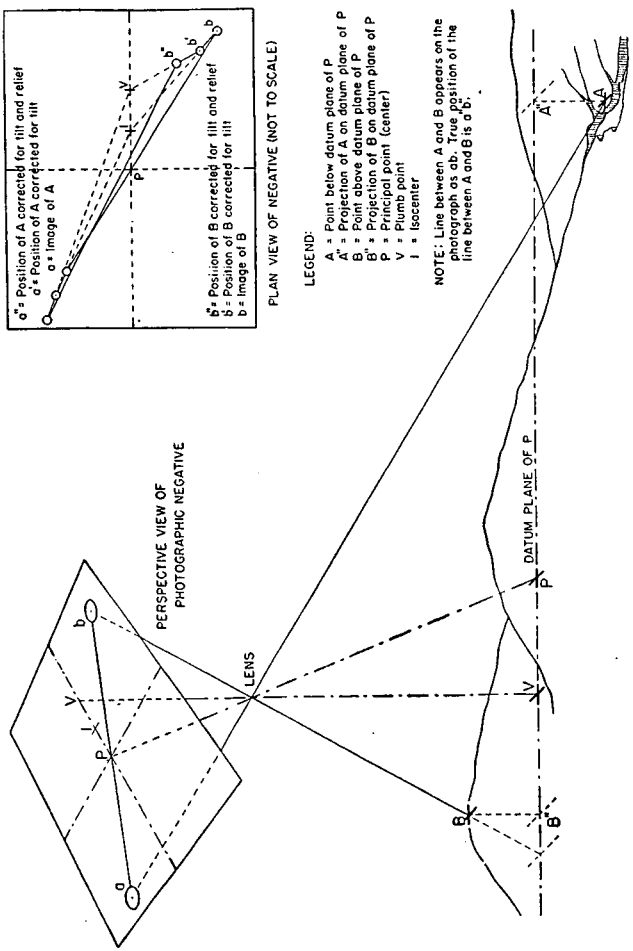

FIGURE 62.—Diagram showing displacement of position on aerial photographs caused by combined effect of relief and tilt.

SECTION VIII

IDENTIFICATION OF TERRAIN FEATURES ON SINGLE PHOTOGRAPH

■ 76. GENERAL.—*a. Topographical identification.*—Topographical identification is the art of identifying visible features of terrain from their images on a photograph, or in deducing the existence of hidden features by their characteristic effects on images of visible features. For instance, roads, railroads, houses, woods, brush, orchards, cultivated lands, etc., are easily identified, and in general closely resemble the conventional signs by which they are represented on maps. On the other hand, the existence of a small stream in heavy woods is inferred by the irregular variation in the density of the woods and association with visible parts of the local drainage net. Likewise, the existence of an invisible stream may be inferred by the narrow irregular band of brush or trees through cultivated lands, or the existence of a fence or land subdivision from a straight hedge line. Successful identification implies familiarity with the characteristics of vertical images and intelligent association of visible effects with hidden causes.

b. Tactical interpretation.—Tactical interpretation of aerial photographs is an art highly developed by the staff intelligence personnel of all armies during the World War. It is properly a specialty of the intelligence sections of staffs; is an advanced phase of aerial photograph reading; and implies tactical experience and knowledge. For treatment of this subject, see FM 30–21.

■ 77. MARGINAL DATA.—As aids in reading and use, aerial photographs to be used individually will have information along the black strip at the bottom, reading from left to right as follows:

a. An arrow ½ inch in length in the lower left corner of the negative indicating north, with letter N superimposed over the center of the shaft.

b. Name of locality or nearest locality.

c. Approximate military grid coordinates of the center of the photograph.

d. Scale of the photograph expressed as a representative fraction, in case of a vertical; altitude above the ground in feet and focal length of camera, in case of an oblique.

e. Hour.

f. Date arranged in the following order: day, in figures; month, in letters; and year, in figures.

g. Designation of squadron.

h. Serial number of negative. For example, the following is the legend on a vertical:

Saranac, N. Y.–(321–437)–1:20,000–(2:00 PM)–(24–Aug–40)–97th–M5.

■ 78. ORIENTATION.—The pictorial effect of an aerial photograph is influenced by shadow. In order that this effect will aid rather than hinder the interpretation of the photograph, the lighting conditions as they occurred in nature at the time that the photograph was taken should be simulated. To do this the photograph should be oriented so that the rays of light from a window or an artificial source strike the photograph from the same general direction as did the sun's rays on the ground. If this is not done, the effect of the light is contrary to that of nature and high ground appears to be a depression and vice versa, to the confusion of the interpreter (fig. 63).

■ 79. IDENTIFICATION OF OBJECTS.—The identification of objects on an aerial photograph or a mosaic is effected through four means as follows:

a. Shape of object.

b. Relative size of object.

c. Tone, or shade of gray, in which object appears.

d. Shadow which object casts.

■ 80. SHAPE.—On a photograph taken from the ground or on an oblique, objects appear in profile as is customary for the eye to view them. On a vertical photograph they appear in plan. A knowledge of their characteristic appearance is best gained by comparison of the photographic image with the object on the ground or with the map symbol representing it.

■ 81. RELATIVE SIZE.—The relative size of an object is a valuable aid in reading photographs. A truck on a road

gives an idea of the road width; outlying residential houses may be compared to warehouses, etc.; and in many parts where farming is intensive, the size of farm blocks offer a means for comparing sizes of objects.

■ 82. TONE.—The shade of gray in which an object appears is known as the tone of the image. It is due almost entirely to the amount of light which is reflected by the object to the camera. The more light reflected by the surface of an object toward the camera, the whiter it appears on the photograph. A surface which reflects no light toward the camera appears black on the photograph. The amount of light reflected depends on the nature and texture of the surface and the angle at which it reflects light toward the camera. Therefore the tone of an object on two consecutive photographs of a strip will vary because the reflection of the sun's rays on the two photographs will not be at the same angle. Because of the preponderant effect of texture, the tone of objects will often appear much lighter or darker than the color would appear to warrant. The following tone effects should be understood:

a. A smooth surface is a good reflector of light and appears white when the camera is in that position which catches the reflected rays of the sun. However if the light is not reflected to the camera, a smooth surface will be dark. The image of smooth water, which is an example of such a surface, is found sometimes to appear to be light and sometimes dark depending upon the angle at which the sun's rays fall upon it.

b. The majority of natural surfaces reflect light in all directions and appear intermediate in tone because some of the reflected light finds its way to the camera.

c. Since not all reflecting surfaces, for example, roofs and sides of slopes, are level, there may be some, no matter what the position of the sun, which will reflect the light and appear white.

d. Rough surfaces reflect light at many different angles in an amount depending upon the nature of the object. Their tone is usually an intermediate one. Roads, unless tarred or oiled, are by nature good reflectors of light and possess a surface sufficiently rough in texture to reflect light through a wide range in position of the sun. As a result, roads almost invariably show as a light line.

e. Any change in the texture of a portion of an object is evident on an aerial photograph through a resulting difference in tone when compared with the other portions. Thus the trampling of a field of grass by walking across it alters the reflection of light and registers a difference in tone on a photograph.

①

FIGURE. 63.—Effect of shadow upon perception of relief. The two illustrations are an identical photograph differing by 180° in orientation.

■ 83. SHADOW.—The effect of shadow is a most important consideration in the interpretation of vertical aerial photographs and mosaics. The shape of an object is often more discernible by the shadow it casts than by either its image or its tone. This is because its vertical dimensions shown by the shadow may be more characteristic than its horizontal

dimensions which are shown by the image; or its tone may blend into the surrounding landscape while its shadow may stand out in contrast. The effect of shadow is an index to valuable military information such as the approximate height, the number of spans and type of a bridge, the height of trees, the shape and height of buildings, and the depth of cuts,

②

FIGURE 63.—Effect of shadow upon perception of relief. The two illustrations are an identical photograph differing by 180° in orientation—Continued.

pits, and quarries. A shadow will sometimes make the general character of relief discernible but, as has already been mentioned, if the photograph is not held so that the direction of the shadows coincides with the observer's sense of direction of the source of the light, the effect is reversed and a depression will appear to be an elevation. This is illustrated in figure 63.

① Summer.

FIGURE 64.—Effect of season.

② Winter.

FIGURE 64.—Effect of season—Continued.

■ 84. PHOTOGRAPHY.—In order to reduce the length of shadows, photography is usually undertaken when the sun is 3 hours or more above the horizon. Light may be diffused by excessive moisture or dust in the atmosphere, resulting in lack of definition in the prints. Intense light produces sharp definition of detail and sharp shadow contrasts. The high-angle sun around noon produces the least shadow effect, and photographs taken around noon are best suited for study of detail through forest canopies and for depicting exact outlines. The low-angle sun, morning or afternoon, produces the greatest shadow effect. Low-lying solid cloud masses effectively prohibit high-altitude photography, and broken clouds seriously interfere by producing white spots on pictures and cloud shadows on the terrain.

■ 85. EFFECT OF SEASON (fig. 64 ① and ②).—Seasonal changes produce corresponding characteristic changes in the physical appearance of terrain on aerial photographs. In summer, deciduous forests show impenetrable expanses of luxuriant treetops, resembling the effect produced by the conventional signs used on some topographical maps. Lesser detail of the terrain is largely hidden. The line of demarcation between forest and open areas is sharply and exactly defined. In winter, deciduous forests on large-scale photographs show a confusion of tree skeletons through which the light penetrates to reveal roads, trails, drainage, and relief with good effect. The line of demarcation between forested and open terrain is not so clear, however, as on small-scale photographs; the tangle of tree trunks and limbs imparts a blurred appearance to the terrain. The appearance of grass and farm land on aerial photographs changes with the seasonal state of culture. Streams in the wet season are broad and may cover extensive back-water areas in flood. The same streams in the dry season may show dry beds or insignificant threads of water. Snow in winter may completely blanket an area which is normally rich in detail.

■ 86. TOPOGRAPHICAL FEATURES.—*a.* Woods on aerial photographs appear as dark masses of irregular outline. The exact shape, size, and density are much more clearly and accurately shown than on the average topographical map. The seasonal characteristics are reflected in the photographs.

In winter photographs of deciduous forests, the leafy canopy is absent, exposing substantially all ground detail which would be wholly or partially obscured in summer photographs of the same forests. Evergreen forests show dark and dense in all seasons (fig. 65 ① and ③).

① Woods, improved and unimproved roads, gravel (or borrow) pit in left foreground.

FIGURE 65.

b. Brush appears similar to light woods but may be distinguished by its sparse character and lack of height (fig. 65②).

c. Bodies of water have a characteristic appearance appreciably lighter or darker than the surrounding land, de-

pending upon the amount of reflection from the surface when the photograph was made (fig. 65③).

d. Streams appear in characteristic wavy traces and show presence of water by darker or lighter lines. In woods, the exact location of small streams may be difficult if not im-

③ Stream partly obscured by woods.

FIGURE 65—Continued.

possible to determine except by reference to a map or inspection of the ground. The visible evidences of such streams are breaks or variations in density of the forest canopy (fig. 65②, ⑤, and ⑦).

e. Cultivated fields show clearly as rectangles or irregular figures of definite shapes and shades. The nature of the

crop usually cannot be determined from the face of small-scale photographs but may be recognized on large-scale photographs. Grain in shocks is conspicuously shown by regularly spaced dots in a lighter background. Fields from which crops have been harvested show light areas. Fields

③ Cultivated fields, woods, orchard, and river.
FIGURE 65—Continued.

with heavy standing crops and grasslands show dark areas. On large-scale photographs they present rough surface appearances. Plowed fields show distinct shading (fig. 65③ and ④).

f. Fences, on large-scale photographs, are distinguished by shadows of the fence posts. On small-scale photographs,

fences are inferred from hedge lines, section lines, outlines of cultivated lands, and the characteristics of paths, trails, and roads (fig. 65⑥).

g. Roads show up in general as light lines or narrow bands—the more used the lighter the appearance. Improved roads

⑥ Railroad, including main line, branch line, siding, and railroad cut.

FIGURE 65—Continued.

show regularity in width, long tangents, and easy curves. The hard surface is clean-cut in outline and may show dark along the middle from the oil drips of automobiles, and light along each edge. Unimproved roads are of irregular width and trace, and may contain sharp turns. Evidence of condi-

tion of road surface is usually apparent from blemishes, shadows, and color variations (fig. 65① and ⑦).

h. Railroads show straighter, darker traces than highways, have fewer changes of direction, long easy curves, and heavy cuts and fills (fig. 65④ and ⑤).

⑤ Railroad bridge over a small stream (at left), overpass (at right).

FIGURE 65—Continued.

i. Small bridges may be looked for at all lesser stream crossings and may be identified by the narrowing of roadbed and shadows cast.

j. Buildings show as indistinct roof images and are sometimes difficult to distinguish from blemishes on prints. The

decisive evidence of the presence of a building is provided by its shadow. Groups of buildings may be blurred by the collective shadow effect. The shape of the shadow is an index of the type and size of the building. The building site is usually the terminus of a road or path (fig. 65③ and ⑥).

⑥ Improved and unimproved roads, trails, and paths.

FIGURE 65—Continued.

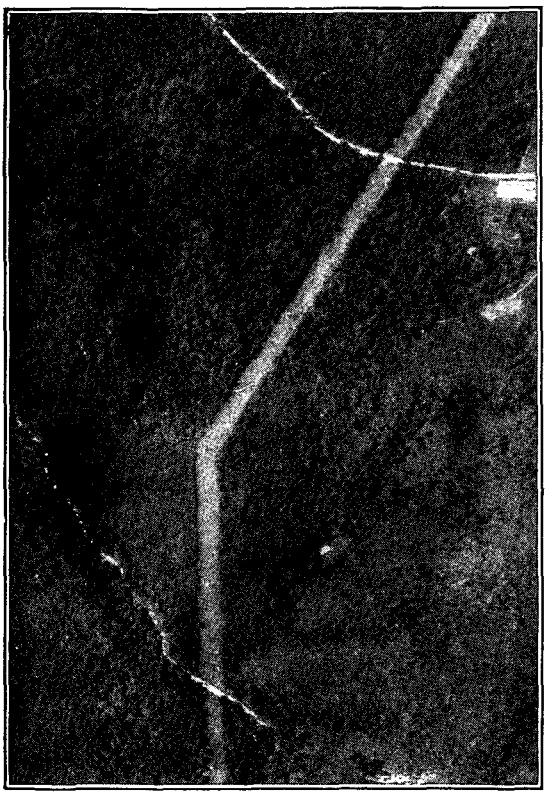
k. Villages and towns are easily distinguished and appear much the same as they do on maps.

l. Trails and paths appear as irregular white bands, lightness and width indicating degree of use (fig. 65⑥).

m. Works of man appear in straight lines, in geometrical form, in unnatural regularity, and relation (fig. 65⑦).

n. Natural features occur in irregular lines, without precision of form and relation.

■ 87. MILITARY FEATURES.—Military works and activities produce characteristic images and terrain effects which make aerial photographs one of the most important sources of



© Slashing for high tension electric power line, stream, and road.

FIGURE 65—Continued.

combat intelligence. FM 30–21 covers this highly important subject.

■ 88. RELIEF.—Single vertical photographs afford only certain clues in regard to relief. Figure 66 represents an untrimmed

vertical photograph from the B (central) chamber of a T–3A camera. Compare this photograph with a sketch of the same area shown in figure 67. The most important clues are those afforded by streams and ponds which indicate low ground. Other clues indicating relief are the alinement

FIGURE 66.—Photograph made with B (central) chamber of Air Corps five-lens T–3A type camera.

and grading of roads and the shadows cast on and by slopes; these, especially the latter, may be very misleading. Direct evidence of relief can be obtained only by stereo examination of an overlapping pair of aerial photographs.

SECTION IX

STEREOVISION AND EXAMINATION

■ 89. STEREOVISION.—*a. General.*—The ordinary vertical photograph has a flat appearance, which makes it difficult to distinguish between hills and valleys. If two overlapping vertical photographs are viewed either with the naked eyes or

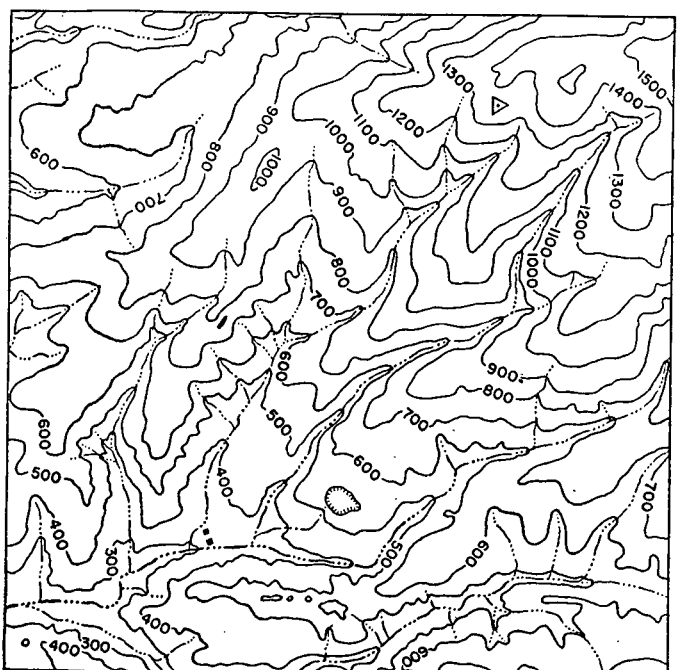


FIGURE 67.—Sketch of area shown in figure 66, representing relief (other detail omitted).

with some type of stereoscopic instrument, the observer will get the effect of depth or relief. This type of study gives valuable training in the understanding and reading of single vertical photographs and photomaps. There are several methods which will assist in acquiring this ability and each individual should experiment until he finds the method which

gives the best results. This ability comes very quickly to most men; others will have to use patience and perseverance to obtain it. Experience with large groups of men reveals that anyone with eyes good enough to be in the Army can acquire the ability to see stereoscopically. Stereo studies properly done put no strain on the eyes, and some oculists even prescribe similar exercises to strengthen the eyes. However, when magnifying spectacles are used, they should be removed from the eyes before looking up from the photographs.

b. Stereogram.—A pair of small pictures, geometric figures, or portions of two overlapping aerial photographs arranged for stereovision is called a stereogram. Figure 68 shows four simple stereograms; figures 69 and 70 show portions of aerial photographs arranged as stereograms.

c. Stereo-pair.—Two vertical photographs of an object or group of objects taken from the same elevation from two different camera positions and with an overlap of not less than 60 percent nor more than 75 percent are known as a stereo-pair (see fig. 72).

d. Stereo-triplet.—Three verticals such that the entire area of the center picture is overlapped by the other two is called a stereo-triplet. For methods of mounting, tilting, marking, etc., see FM 30–21.

e. Anaglyph.—An anaglyph is a form of stereogram on which a picture is formed by almost superimposing an image in red over one in blue to secure stereo or perspective effect when observed through an anaglyphoscope—spectacles with one blue and one red lens. Several methods of indicating perspective relief of the terrain are in use. With aerial photographs available, the simplest method is the overprinting in two colors of a stereo-pair. Another method, the anaglyph of the contoured map, is the result of an expensive and time-consuming process. The polaroid anaglyph is still another form of portraying three dimensions. The anaglyph, as a rule, gives less detail than a stereo-pair of the same scale. However, the anaglyph is of great value in stereo instruction. For an illustration of an anaglyph, see TM 5–230.

■ 90. STEREOVISION EXERCISES.—*a. Preliminary exercises.*—Experience has shown that the best method of quickly ac-

quiring the ability to see photographs stereoscopically either with the naked eyes or with an instrument is to practice certain preliminary exercises. Figure 71 illustrates a simple device which can be quickly and easily prepared by the student for use in these exercises. Cut two pieces of white cardboard each 5 inches long by 3 inches wide. At the exact center of each piece of cardboard describe a circle exactly 1½ inches in diameter. Number these pieces of cardboard 1 and 2, respectively. On card No. 2 draw a smaller circle exactly ⅜ of an inch in diameter, with its center 1⅛ inches to the left of the center of the large circle. Draw a cross ⅜ by ⅜ inch with its intersection 1⅛ inches to the right of the center of the large circle. Label the reverse of card No. 1 as No. 4, and the reverse of card No. 2 as No. 3, and draw a line on each as illustrated in figure 71. Now cut out the large circle from each card. Do *not* cut out the small circle on card No. 2. Sit in a chair and look across the room at a fairly distant wall. Hold card No. 1 about 6 inches in front of the eyes, with the hole directly in front of the bridge of the nose. Look at the wall, through the hole, with both eyes open. Note that there are apparently two distinct holes in the card. This is the first step of stereovision. Take card No. 2. This card is like No. 1 except that it has a circle printed on one side of the hole and a cross on the other side. The method of using this card is exactly the same as No. 1. However, when you see the two holes you will also see between them the circle with the cross inside. Concentrate your eyes on the image. Twist the card and notice how the cross moves with relation to the circle. You will note that if the cross moves up, the circle moves down and vice versa. The holes may appear to be slightly overlapping at some times; at other times the circle and the hole may appear to be floating in the holes entirely off the card. Try holding a strip of paper between the two holes with the images of the circle and the cross on the strip. While you are seeing the hole double, move the paper nearer and farther from the eyes. Watch what happens to the image. When you can see these images, and thus see double, you have accomplished the necessary muscular control to read a stereogram. Practice with this card until you can see these images without effort. When you have acquired skill with No. 2, go on to Nos. 3 and 4. These are used together, No. 3 on the left, No. 4 on the right.

Place the two cards together with the black lines matched and hold them against the nose with the holes in the same position as if they were glasses. The holes should be the same distance apart as your eyes. The distance is normally about 2.6 inches, center to center. Looking through the holes, focus on a distant object. Now move the cards in the direction of this object until they are about a foot from the eyes. You will now see three holes with the object viewed in the center hole. Remember during this that the eyes *must* remain focused on the distant object. When the three holes are seen, the eyes are in the proper position for stereovision. The images of the three holes appear although you are not looking at them. You are looking at the distant object. This is similar to lining up your sights on the target range. You are focusing at the front sight but you see both the bull's-eye and rear sight. Practice at this exercise will enable the three holes to be seen without first focusing on a distant object. This means that you have acquired sufficient muscular control over your eyes to see stereoscopically.

b. Fusion exercises.—The next step is practice in fusing two pictures. In figure 68 the drawings can be fused as follows. Focus the eyes on a distant object. Without changing the focus, bring figure 68 in front of the eyes and about 6 to 10 inches away. As you continue to gaze at the drawing the dots will merge until apparently you have one dot on one figure. You will still get three images but the center one is the important one on which you should fix your attention disregarding the other two outside images. Now see what effect you get with the pair of dots below on figure 68.

c. Exercises for perception of relief.—Figure 68 shows two views each of two geometric figures. Using the same methods as in *b* above, fuse the first pair of drawings, which should cause you to see a square pit with a pyramid sticking up out of the bottom. In other words, instead of a flat geometric drawing, you are seeing a three-dimensional picture. Fuse the other pair of drawings and observe the results.

d. Study of stereograms.—Figures 69 and 70 are stereograms. To see these properly, use the same methods as prescribed above. First, fuse the square points marked *A* in figure 69. You will again get three images, but the center one is the one on which to focus, and is the one on which relief will be visible. If you have difficulty seeing this center image clearly,

hold a piece of cardboard vertically up to the nose so that it is perpendicular to the pictures and one edge of the cardboard lies on the line dividing the two pictures of the stereogram. This will eliminate the two outside images and leave only the center image. Focus on this, and the trees and buildings will appear to stand up high above the page. Practice with figures 69 and 70.

e. Cross-eyed stereovision. — While the great majority of people can see stereoscopically by the method described above, there are a few who may be able to see better by using another method. The difference lies in the fact that in the parallel vision system described above, the right eye looks at the right picture and the left eye at the left picture. In this second method, the right eye looks at the left picture and the left eye at the right picture or in other words with the eyes crossed. In using the stereograms, the relief will be reversed with this method. The hills will look like valleys and the valleys like hills. Therefore, for study of overlapping pairs, the right and left pictures should be placed on the left and right, respectively. This will give the stereo observer using the cross-eyed method the proper effect of relief.

■ 91. STEREOSCOPES.—*a. Types.*—The stereoscopes used for the interpretation of aerial photographs may be classified as mirror, lens, or prism types. The mirror stereoscope (fig. 74) possesses the advantage of a large field of view and is considered to be the most adaptable for general military use. The lens stereoscope (fig. 75), although affording only a limited field of view, has the advantage of permitting the introduction of magnification. The prism stereoscope (fig. 76), which is larger and more expensive than either of the other two types, possesses the advantage of permitting a wide separation of the two overlapping photographs and is therefore particularly suitable for examining T–3A photographs. The instrument illustrated has a magnification of 2 power.

b. Improvised stereoscopes.—A suitable stereoscope for interpreting detail on aerial photographs may be improvised by means of two magnifying glasses of equal power (fig. 77). One glass may be held in each hand and stereoscopic fusion obtained by looking through the inner half of each lens. For more prolonged inspection the glasses may either be

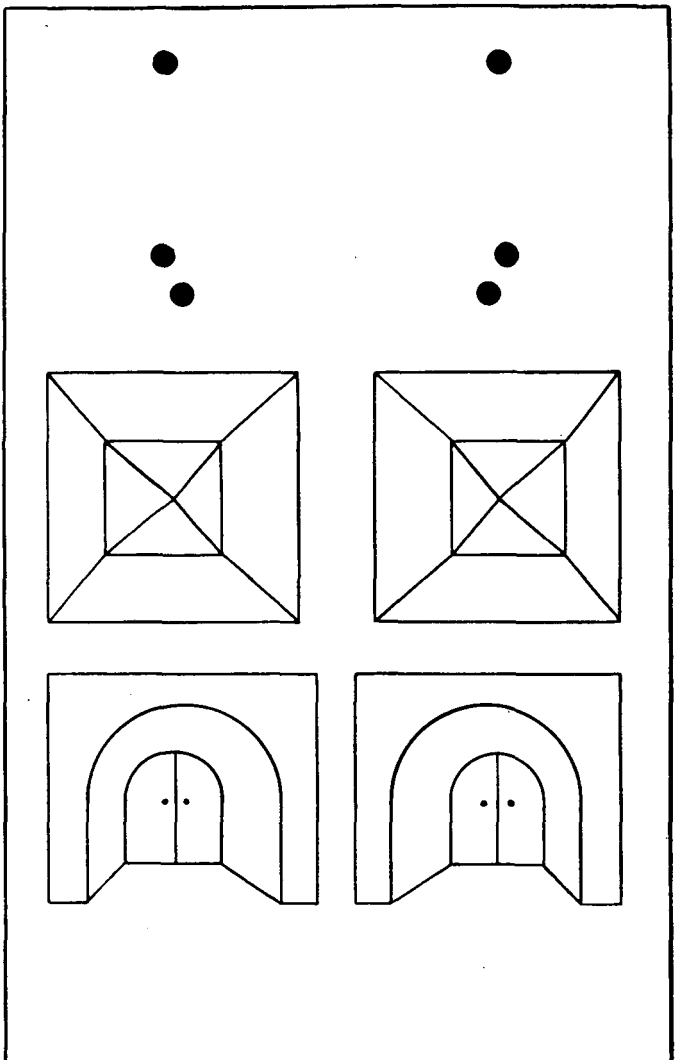

FIGURE 68.—Simple stereograms.

supported on an improvised stand or, if of appropriate size, may be mounted in a spectacle frame. Cellulose tape may be used to hold the glasses to the frame. A pair of strong

FIGURE 69.—Stereogram.

reading glasses will serve as a spectacle stereoscope but will permit only a small separation of the pair of photographs with a corresponding reduction of the effective overlap area.

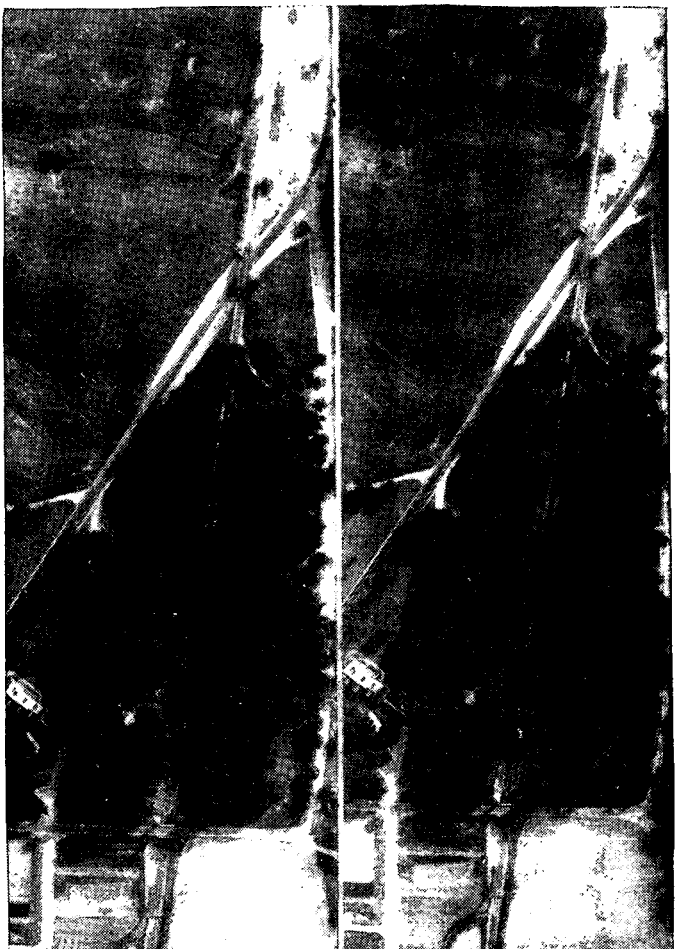

FIGURE 70.—Another view of a stereogram.

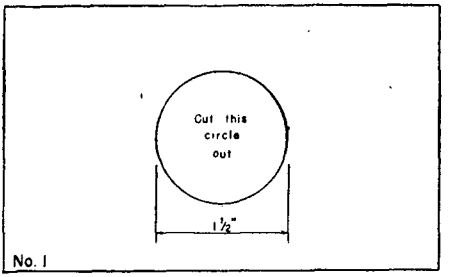

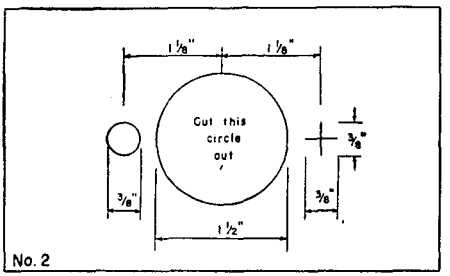

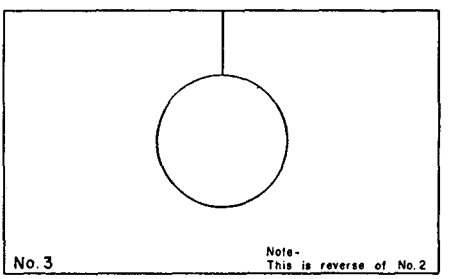

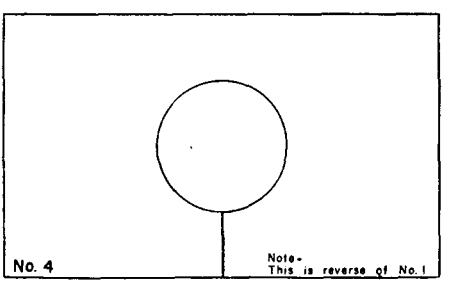

FIGURE 71.—Illustration of cards for use in stereovision exercises.

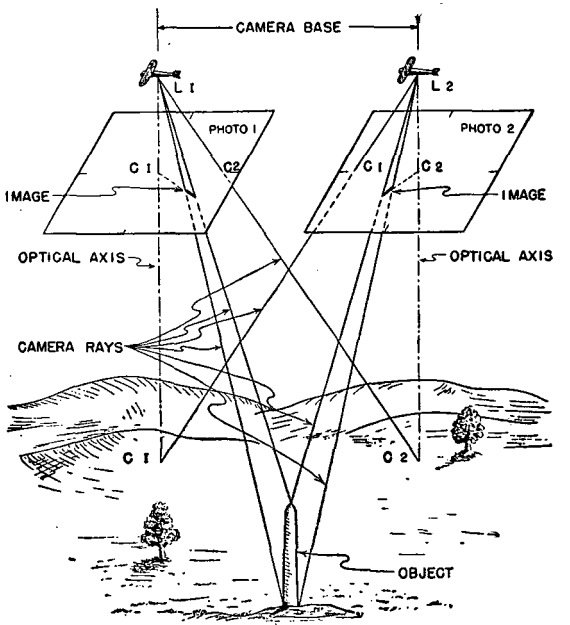

FIGURE 72.—Diagram of a stereo-pair of aerial photographs.

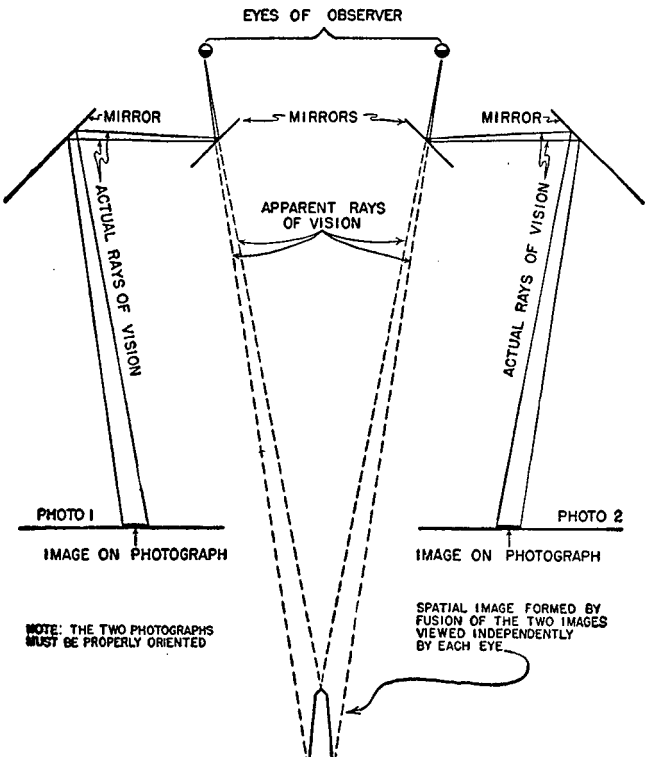

FIGURE 73.—Diagram showing stereo perception.

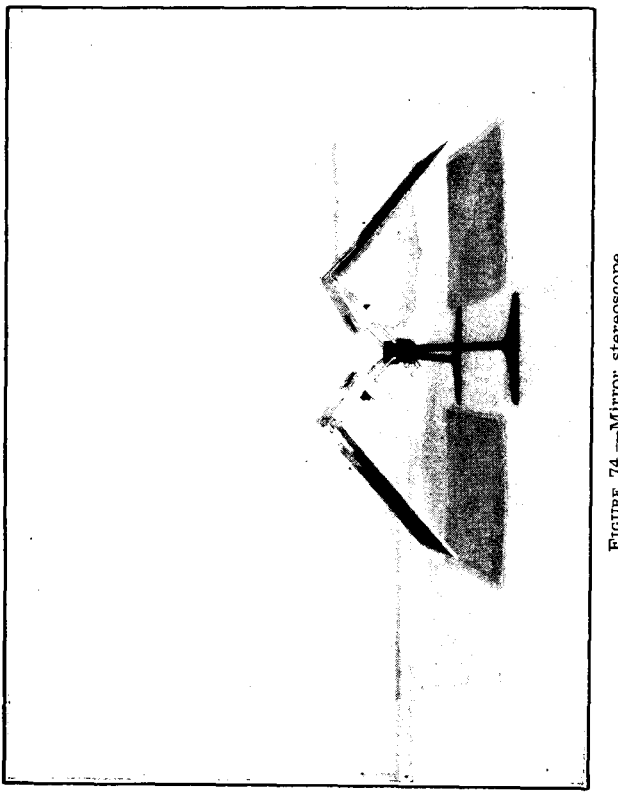

FIGURE 74.—Mirror stereoscope.

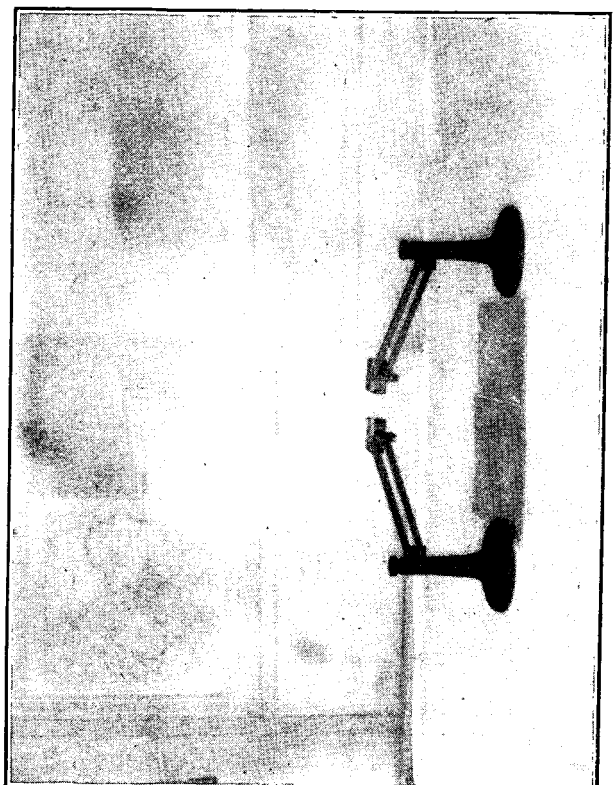

FIGURE 75.—Lens stereoscope.

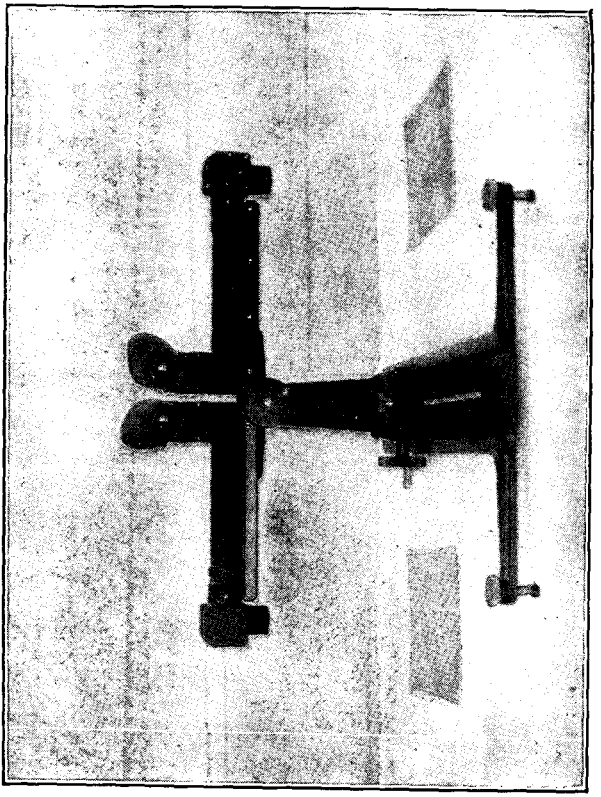

FIGURE 76.—Prism stereoscope.

■ 92. STEREO EXAMINATION OF AERIAL PHOTOGRAPH.—*a. General.*—(1) Appreciation of relative distances is based fundamentally on the slightly different view of various objects presented by each of the two eyes. A person with one eye or a person with only one eye open cannot perceive relative distance any more than a person can perceive depth looking at a single vertical photograph. Under such conditions, distance is sensed only through experience.

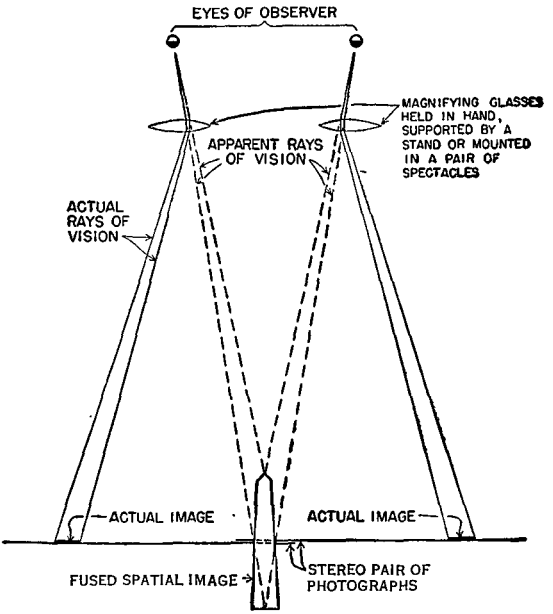

FIGURE 77.—Diagram showing stereo examination by means of improvised lens stereoscope.

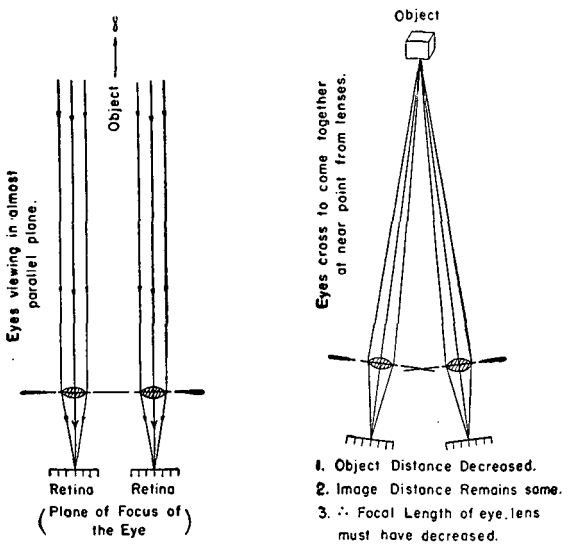
(2) Unaided eyes viewing a distant object (fig. 78①) have their lines of vision almost parallel. As the object comes nearer (fig. 78②), the focal length of the eyelens decreases and depth perception is better. If each eye looks straight ahead with line of vision parallel, and the eyelenses are kept at a short focal length, the two images (fig. 78③) will fuse, the result being the same as in figure 78②. This latter

process usually requires training of the eyes, while with little training stereovision can be obtained with the use of spectacles (fig. 78④).

(3) If two vertical photographs of an object or a group of objects are taken to the same scale from two different camera positions as in figure 72, and each picture is viewed by one eye to the exclusion of the other but both pictures viewed simultaneously (fig. 73), the appreciation of distance is then possible because a different view is presented to each



① Unaided eyes viewing distant object.

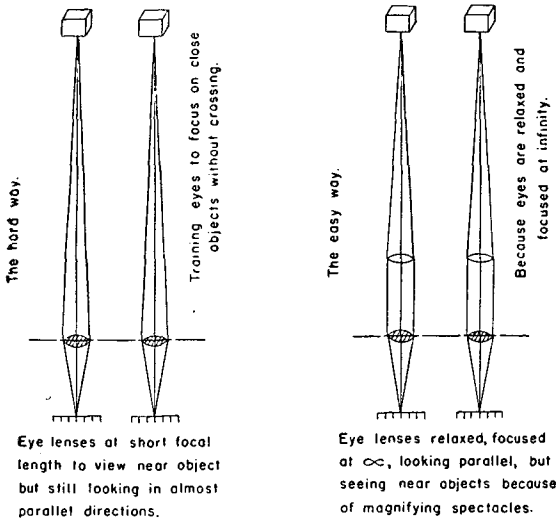
② Unaided eyes viewing very near object.

FIGURE 78.—Stereovision.

of the two eyes as is the case in ordinary vision. In order that a combined or "fused" image may be obtained, certain conditions must be satisfied in the arrangement and in the viewing of the two photographs. These are briefly as follows:

(*a*) Both eyes of the observer should be of equal power or corrected by optical aids, and the two photographs should be equally distinct and equally illuminated.

(*b*) The pictures should be so arranged with respect to each other and to the eyes of the observer that exposure conditions are restored. The distance between the centers of the two photographs corresponds to the base between camera positions, and the positions of the eyes correspond to the positions of the camera lens. The eyes must be parallel not only to the line joining the centers of the photo-



③ Stereoscopic viewing—training to see stereoscopically with unaided eye.

④ Stereoscopic viewing—training to see stereoscopically with spectacles which decrease focal length of eyelens.

FIGURE 78.—Stereovision—Continued.

graphs but also to a line on each photograph drawn between points of detail marking the two corresponding center points. The stereograms shown in figures 69 and 70 are the overlapping portions of two such vertical photographs. They have been mounted side by side in the proper relation with each other to secure stereovision. Any pair of overlapping vertical photos (taken at approximately the same elevation), if arranged in this same manner, can be read stereoscopically.

b. Method.—(1) Place one photo on top of the other so that overlapping detail common to both roughly coincides (fig. 79).

(2) Next note the position of an imaginary line joining their approximate centers. The eye base of the observer must be parallel to this line of centers. Turn the photographs as a unit until the condition is satisfied.

(3) Now separate the photos along the line joining the centers (fig. 80), moving the one on the right to the right and viewing it with the right eye, and the one on the left toward the left and viewing it with the left eye. The exact orientation of the photographs with respect to each other can be obtained by keeping detail, such as roads or streams, which appear in the overlap area parallel to each other. For example, take a road that appears on both photographs. Rotate one photo until the image of the road on this photo is parallel to its image on the other photo. The distance that two objects appearing in the overlap area have to be separated depends on whether the photos are to be examined by the naked eye or by some stereoscopic instrument. For beginners with the unaided eye, this separation of detail should be not more than 1¾ inches. With practice after the steroscopic effect is obtained, the photographs can be gradually separated until a large portion of the overlapping area can be seen. If the study is made first with the right-hand photograph overlapped on top of the left and then with the left-hand photograph placed on top of the right, the entire overlapping area of a 9- by 9-inch stereo-pair with 60 percent overlap can be studied stereoscopically with the unaided eye.

c. Procedure of using stereoscope.—The following procedure should be observed when making a stereo examination of aerial photographs (see also sec. VII, TM 5–230):

(1) Orient the stereo-pair in the direction of flight so that the overlapping detail common to both is roughly in coincidence (fig. 79).

(2) Place the photographs under the stereoscope so that the left print (taken by the camera on the left of the overlap area) is observed by the left eye and the right print by the right eye.

(3) Shift the photographs so as to bring an imaginary line drawn between the center points parallel to the eye base and

in prolongation with one another in the center of the field of view of the stereoscope.

(4) Without changing the relative position of the imaginary lines drawn through the center points, bring together or separate the photographs until stereo conditions of fusion are best fulfilled (fig. 80).

■ 93. FAULTY STEREO EFFECTS.—*a. Faulty stereo orientation.*— Faulty orientation of a stereo-pair with respect to the eye base introduces false parallax difference and lack of correspondence. These make it difficult to fuse detail and cause a diminution of relief.

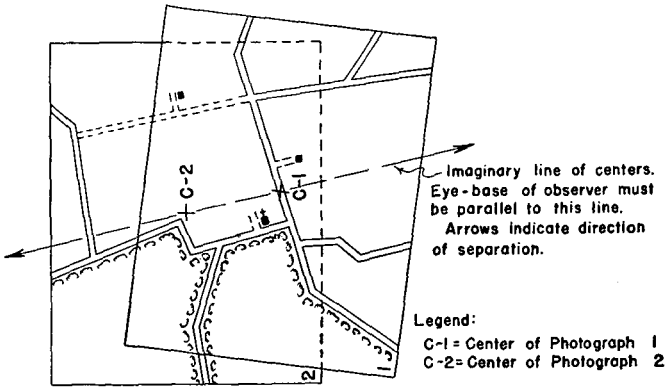


FIGURE 79.—First step in arranging photographs for stereo study (detail in overlap area matched).

b. Tilted photographs.—Photographs which are tilted cannot be brought into accurate correspondence as described in paragraph 92 and sometimes must be shifted as the field of view of the observer is moved from point to point. Distortion of relief results from such a condition.

c. Pseudoscopic effect.—If the position of two photographs forming a stereo-pair is reversed so that the left print (taken by the camera on the left side of the overlap) is viewed by the right eye and the right print by the left eye, the impression of relief is reversed; that is, the point of lowest elevation is reconstructed nearest to the eye and appears to be of high-

est elevation. Practical use may be made of this factor in that drainage lines may be traced by making them appear as ridge lines.

SECTION X

PREPARATION OF AERIAL PHOTOGRAPHS FOR USE AS MAP SUBSTITUTE

■ 94. GENERAL.—In order to make a photograph or groups of photographs sufficiently accurate and detailed for most efficient use, certain mechanical operations must be effected. Certain inaccuracies inherent in a single photograph may

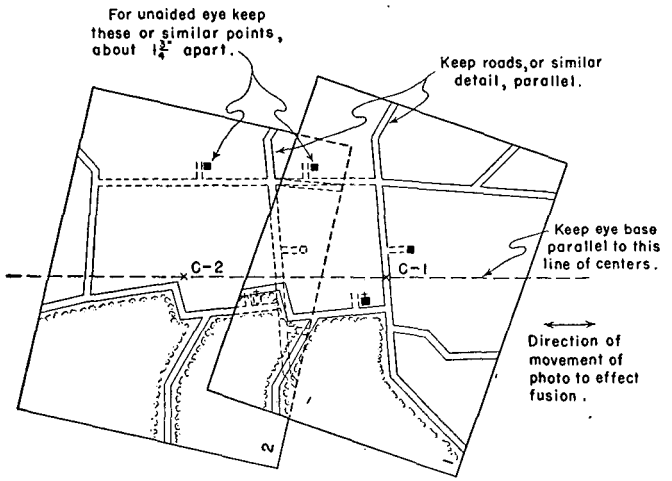

FIGURE 80.—Photographs arranged for stereo study.

be overcome in the compilation and finishing of a group, and with the aid of machines, stereo-pairs may be accurately contoured. By these processes the value of photographs as map substitutes or photomaps is greatly enhanced.

■ 95. SCALE.—An important difference between military maps and vertical photographs used as maps lies in the choice of scales. Military maps conform to a prescribed range of standard scales expressing the relation of ground to map in simple terms. The horizontal scale is uniform throughout the map. On the other hand, the scales of vertical photo-

graphs are dependent principally upon the variable and uncertain factors of lens height, camera tilt, and relief of the ground in the photographic field at the moment of exposure. The scale of a vertical photograph, therefore, not only changes on the several photographs of an overlapping series but is also not uniform on a single photograph. If the degree of scale variation is small the resulting errors become inappreciable, and probably no greater than those which result from average measurements made on a map in the field with the relatively crude instruments used in map reading.

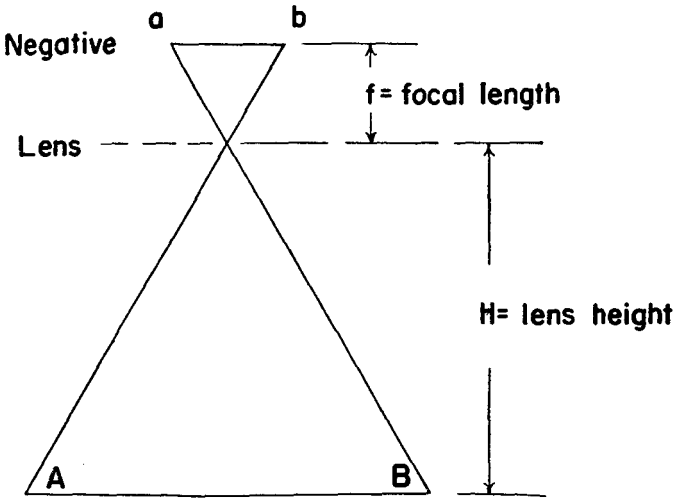

FIGURE 81.—Determination of scale from height.

■ 96. DETERMINATION OF SCALE.—*a. By lens height.*—By inspection of figure 81 it may be seen that, if the ground is assumed to be a plane surface, any distance on the negative, such as *ab*, bears a relation to the corresponding distance on the ground *AB* equal to f/H where f is the focal length of the camera and H is the height of the camera lens above the ground (both f and H being expressed in the same unit of measurement). Hence:

$$RF = \frac{f}{H}$$

Since the altimeter of the airplane usually expresses the elevation above sea level in place of H, the expression H_α—E may be substituted, H_α being the altimeter elevation above

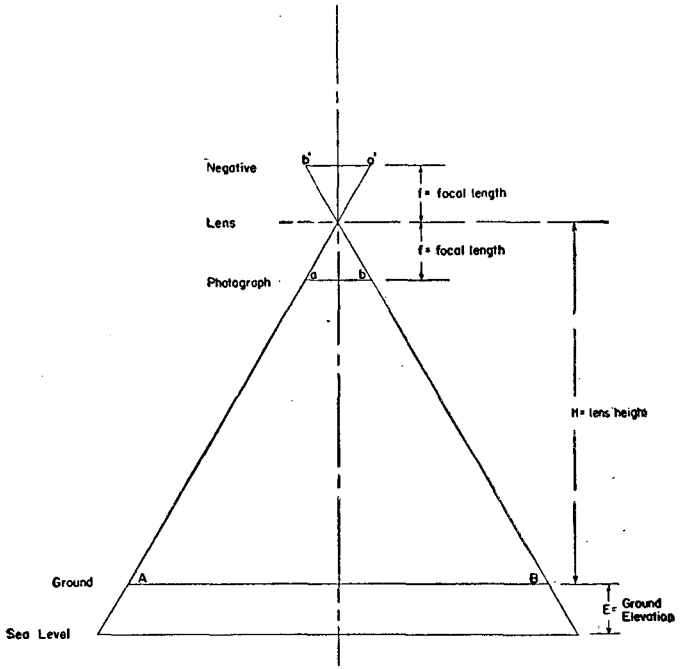

FIGURE 82.—Diagram showing relation of scale, focal length, and lens height.

sea level and E the average elevation of the terrain shown in the photograph (fig. 82). We may accordingly write

$$RF = \frac{f \text{ in feet}}{H_\alpha \text{ in feet} - E \text{ in feet}}$$

Example:

Focal length of camera is 6 inches or $\frac{6}{12}$ feet.
Altitude of the airplane is 10,000 feet above sea level.
Elevation of the ground is 1,000 feet above sea level.

$$RF = \frac{\frac{6}{12}}{10{,}000 - 1{,}000} = \frac{1}{18{,}000}$$

It is usual for a request for aerial photographs to state the scale desired. The flying altitude of the airplane is determined from this formula.

b. By comparison with map or ground.—(1) In *a* above it was stated that the scale of an aerial photograph is equal to the quotient of the focal length of the camera divided by the height of the camera lens. The scale determined by this formula would be the true scale of the entire photograph under the conditions of absolutely accurate altimeter records, complete absence of tilt, and perfectly level terrain. However, altimeter records are often appreciably affected by local

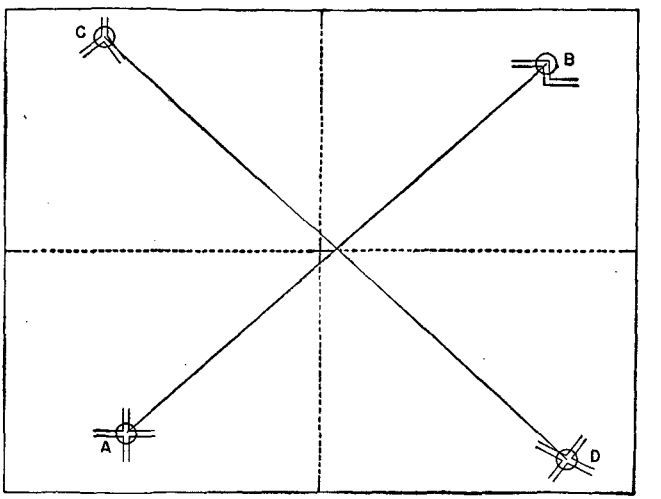

FIGURE 83.—Diagram showing proper location of scale lines.

atmospheric conditions, and the effects of tilt and relief will usually cause some scale variation within the limits of the photograph. For this reason, scale can be determined more accurately by comparing distances measured on the photograph with corresponding distances either on a map or on the ground. Such distances should be between points which are well defined both on the photograph and on the map (or ground). When it is desired to apply the scale to the entire photograph, the distances measured on the photo-

graph should represent the average scale of the photograph. In the discussion which follows, the selected distances are termed "scale lines."

(2) In order to represent the average scale of the photograph, a scale line should extend well across the face of the photograph (fig. 83). Since the effect of tilt is assumed to be radial along a line passing through the center of the photograph and because of its effect in compensating on opposite sides of the photograph, the scale line should pass near to its center. In order that the scale determination will not be affected unduly by relief, care should be taken that there is not a pronounced difference in relief between the points at the ends of the scale line. With the scale line thus determined, its RF can be solved in the same manner as given for maps in paragraph 14; the RF of the scale line being roughly the RF of the photograph.

(3) *Ground.*—The distance between the identified points is measured. Then:

$$\text{RF of the scale line} = \frac{\text{photo distance in inches}}{\text{ground distance in inches}}$$

Ordinarily it should prove convenient and satisfactory to select two points on a straight stretch of a highway and use the distance along the highway as the scale line in the computation of the RF of the photograph.

(4) *Map.*—(*a*) The most simple method of determining the RF of a scale line from a map of known RF is by converting the distance on the map to the equivalent distance on the ground and proceeding as in (3) above.

(*b*) A more rapid method of determining the RF of a scale line is by the direct formula:

$$\text{RF of scale line} = \frac{\text{photo distance in inches}}{\text{map distance in inches}} \times \text{RF of map}$$

(*c*) Although for terrain of low relief one such well-chosen scale line will often suffice, it is preferable that the average scale of the photograph be determined from two or more scale lines, the value assigned to the denominator of the RF of the photograph being the average of the denominators of the computed RF's of each scale line. Thus we may write

$$\text{Average RF of the photo} = \frac{1}{\text{mean of the denominators of the RF's of the scale lines}}$$

Example:

Distance *AB* on photo=8 inches
Distance *AB* on map=6 inches
Distance *CD* on photo=9 inches
Distance *CD* on map=6.65 inches
RF of map is 1:20,000

Using scale line *AB*

$$\text{RF}=\frac{8}{6\times 20{,}000}=\frac{1}{15{,}000}$$

Using scale line *CD*

$$\text{RF}=\frac{9}{6.65\times 20{,}000}=\frac{1}{14{,}778}$$

Average RF of the photo $=\frac{1}{\frac{1}{2}(15{,}000+14{,}778)}=\frac{1}{14{,}889}$

For ordinary purposes a 1:15,000 scale will serve in measuring distances on the photograph.

■ 97. SCOPE.—The area covered by an aerial photograph can be calculated readily by either of the following methods:

a. By the ratio $\frac{\text{ground distance}}{\text{photo distance}}=\frac{H}{f}$ (*H* and *f* being expressed in the same units of length)

Therefore the ground scope of any photograph $=w\frac{H}{f}\times l\frac{H}{f}$

where w=width of the photograph
l=length of the photograph
H=height of camera lens
f=focal length of camera

For K–3B type photographs (f=12 inches, w=7 inches, l=9 inches)

$$\text{Scope}=\frac{7}{12}\times\frac{12}{12}\times H\times\frac{9}{12}\times\frac{12}{12}\times H=\frac{7}{12}H\times\frac{9}{12}H \text{ square feet}$$

For T–3 type photographs (f=6 inches, l=w=32 inches)

$$\text{Scope}=\frac{32}{12}\times\frac{12H}{6}\times\frac{32}{12}\times\frac{12H}{6}=\frac{16}{3}H\times\frac{16}{3}H \text{ square feet}$$

Thus at a height of 12,000 feet the scope of these photographs is as follows:

For the K–3B type, scope $=\frac{7}{12}12{,}000\times\frac{9}{12}12{,}000=7{,}000\times 9{,}000$ square feet=2.26 square miles.

For the T–3A type, scope=64,000×64,000 square feet=146.9 square miles (overall).

b. By the ratio, $RF=\frac{\text{photo distance}}{\text{ground distance}}$

Therefore scope$=\frac{w}{RF}\times\frac{l}{RF}$

where w=width of the photograph
l=length of the photograph

Example:

For a K–3B photograph having an RF of $\frac{1}{12,000}$

$$\text{Scope}=\frac{7\ (12,000)}{12}\times\frac{9\ (12,000)}{12}$$

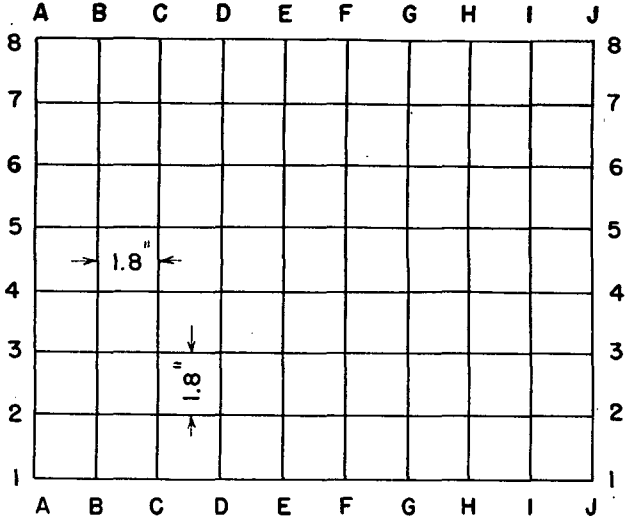
$$=7,000\times9,000 \text{ square feet}=2.26 \text{ square miles}$$

■ 98. GRAPHIC SCALE.—The preparation of a photograph for use as a map may include the construction of a graphic scale in yards or other appropriate units. When given, or having determined, the RF of the photograph, the graphic scale is constructed by the methods employed in constructing such scales for maps or sketches (see sec. II). On mounted photographs the scale so constructed should be placed on the lower margin of the mount, and if desired may extend entirely across the mount. On unmounted photographs, it should usually be placed on the back of the print in order not to obscure unnecessarily the detail on the face of the print. See paragraph 105 for the atlas grid.

■ 99. TO TRANSFER DETAIL OR CHANGE SCALE.—*a. By photography.*—Photographs may be enlarged or reduced by rephotographing when the necessary facilities are available. The resulting prints are usually not as good as the originals, and enlargements lose definition of detail.

b. By rectangular grid (fig. 84).—For average military purposes the detail of a vertical photograph may be roughly enlarged, reduced, or transferred by means of a special rectangular grid on the photograph. To transfer by this method at a changed scale proceed as follows:

(1) Fit a transparent overlay to the photograph and lay out on it a rectangular grid to a scale which is some fractional part of 1.8 inches (atlas grid, par. 105).



ENLARGEMENT
Scale 1:10,000

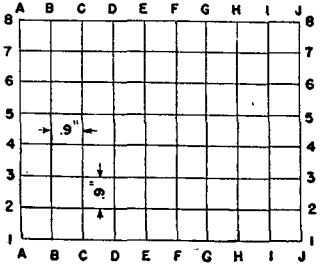


PHOTO
Scale 1:20,000

FIGURE 84.—Change of scale by rectangular grid method.

(2) Trace through on the overlay the topographical detail which it is desired to transfer.

(3) Lay out the atlas grid on a suitable sheet of paper at the new selected scale.

(4) Copy from the photograph overlay to the changed scale overlay (or map), square by square, the detail appearing therein in its proper relation to the square.

(5) For more accurate detail, construct a grid card for each scale. With these cards, important features may be much more accurately located.

Caution: It is to be understood that the above methods for changing scale merely result in copying or reproducing the detail as it appears on the photograph and in no sense should be considered as methods of rectification or elimination of inherent errors.

■ 100. DISTANCE.—Having determined the RF of a vertical photograph intended for use as a map and having constructed a graphical scale of yards for use on it, the photograph reader is ready to scale distances as required. The methods used in the measurement of horizontal distances on maps explained in section II or some elementary text, are also applicable to vertical photographs used as maps. It should suffice to state that the paper strip and graphic scale method is probably the most universal and satisfactory general method. The engineer's scale and the map measurer each serve in their respective fields of usefulness.

■ 101. DIRECTION.—*a.* It has been stated that in a vertical photograph which is of average rolling or fairly flat terrain and which has a small angle of tilt, the combined effect of errors over the center half of the photograph is entirely negligible for ordinary use as a map and is rarely prohibitive even in the marginal areas. Therefore, for normal military uses, direction angles and azimuths on a photograph have the same significance as they do on maps, and may be measured and laid out with the protractor exactly as is done with maps. The methods of measuring angles and directions on maps in section III apply.

b. In order to lay out or measure directions on a photograph with the facility with which this can be done on a map, it is obviously necessary to equip the photograph with

the magnetic north, true north, or grid north line. When practicable and desirable, all three of these are shown. Magnetic north, however, is the most suitable base direction for

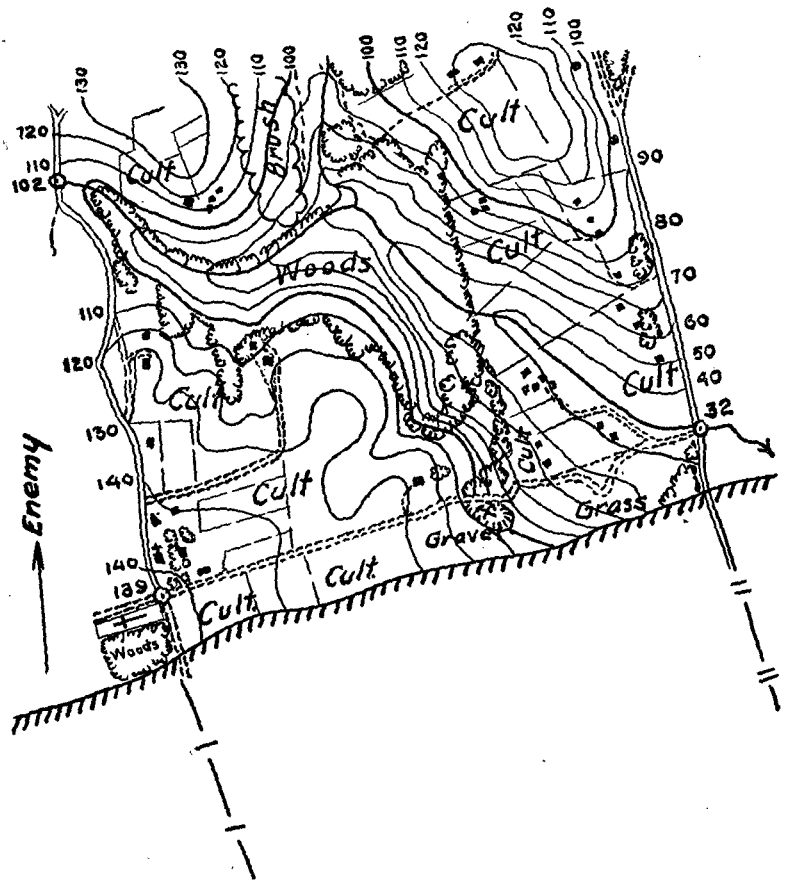


FIGURE 85.—Overlay of section of contoured aerial photograph.

photographs intended as substitutes for military maps and is the most available base direction for photographs of unmapped country. The magnetic north line may be traced

on the photograph negative with a stylus to print in black lines for reproduction in quantity.

■ 102. ELEVATION.—The determination of elevations by the use of a formula such as was developed in paragraph 73*b* is theoretically possible. The accuracy of results secured from the use of such a formula is dependent upon the accuracy of measurements on the face of the photographs, the reliability of corresponding map and ground positions, the determination of the lens height and elevation of the ground plumb point, and the assumption that the effect of tilt is negligible. Possible error introduced from these sources cannot be discounted in the evaluation of the character of the results. The most practical method of determining elevations is by trigonometric leveling. In order that elevations may be determined accurately direct from aerial photographs, photogrammetric equipment must be employed.

■ 103. CONTOURS.—*a.* In unusual situations it may be desired to contour a photograph in the field. This may be done by copying contours onto the photograph from an existing contoured map of the area, or by interpolating logical contours from selected spot elevations determined on the ground. Contouring should be done with the aid of a stereoscope.

b. To contour accurately an aerial photograph it is necessary to have numerous ground control points, and the drawing of the contour lines must be done with the aid of a stereo-comparagraph or some similar instrument. When these and other photogrammetric instruments are used, contouring is done by trained personnel. Engineer topographic organizations prepare accurate large-scale topographic maps, solely from photographs taken on planned flights over large areas upon which ground control has been established.

c. Ridge and streamlining may be accomplished in the field on a photograph or stereo-pair, as an aid to interpretation of relief. After this has been done, contouring may be accomplished as described in *a* above and then placed on an overlay (fig. 85).

■ 104. LOCATION OF MAGNETIC NORTH ON PHOTOGRAPH.—*a. When map showing magnetic north is available* (fig. 86).—Select two points identifiable both on the photograph and on the map and so located that the line joining them passes

through or near the center of the photograph. The direction of such a line will be little if at all affected by relief and tilt. By means of a protractor, determine from the map the magnetic azimuth of the line joining the points selected. From the corresponding line on the photograph, shown in figure 86 as *AB*, turn off counterclockwise an angle equal to the magnetic azimuth measured on the map to *AM*. This establishes on the photograph the magnetic base corresponding to that shown on the map.

b. By means of compass.—Orient the photograph by corresponding points on the photograph and on the ground.

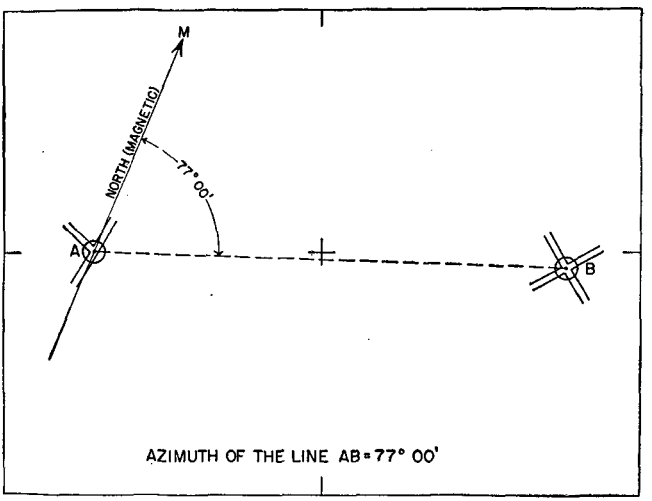

FIGURE 86.—Diagram showing method of locating magnetic north line on photograph.

Place a compass on the photograph and draw a line on the photograph parallel to the direction of magnetic north indicated by the compass needle.

■ 105. ATLAS GRID (fig. 87).—*a.* Because of variation in scale, other inaccuracies, and the difficulty of locating grid lines, the military grid is not used on single photographs or uncontrolled mosaics. Instead of the military grid, the atlas grid is used. The grid lines of the atlas grid are always 1.8 inches

apart regardless of the scale. With this interval, on a 1: 20,000 photo, the grid lines are about 1,000 yards apart. The lines are numbered from the bottom up and lettered from left to right. Thus the origin of the coordinates is at the lower left corner of the photo; numbers 1, 2, etc., upward; letters *A*, *B*, etc., to the right; the coordinates of the origin being (*A*.0—1.0).

b. To superimpose atlas grid on photograph.—In the process of reproduction, the edges of a photograph may vary

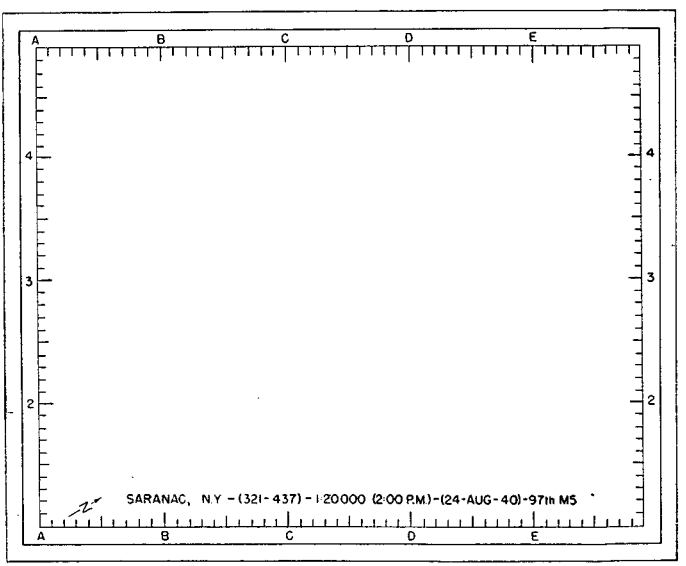

FIGURE 87.—Atlas grid and marginal data.

and successive prints may differ. In order to provide an accurate origin from which to measure, collimation marks are registered at the center of the four sides of a vertical photograph (par. 62*b*(1)(*b*)). To superimpose an accurate atlas grid on a photograph, the true edges must be established from the collimation marks, and the grid lines then spaced 1.8 inches apart beginning at the intersection of the true edges at the lower left corner of the photograph. Thus on a 9- by 9-inch print the true edges would be 4½ inches from

a line drawn between the opposite collimation marks, and the 1.8-inch grid would be laid off along these true edges. Figure 87 represents a 7- by 9-inch photograph which is not quite full size. If the photo were exactly 9 inches wide the *F*-coordinate line would exist. It must be borne in mind that the atlas grid has no definite limits as to the total area covered by it.

■ 106. MILITARY GRID.—*a. General.*—While the military grid is not used on single photographs or uncontrolled mosaics, it is highly desirable on controlled mosaics and photomaps made from them. Because of the inherent characteristics of mosaics, the military grid when superimposed upon them is only approximate. If a gridded map of the photographed area is available, the military grid may be transferred without difficulty to the mosaic by proceeding as follows:

(1) Three points, *A, B,* and *C* are selected on the photograph (fig. 86) which can be readily identified on the map. For greatest accuracy, the points selected should be well-spaced around the central area of the photograph.

(2) Determine the average scale of the photograph by the comparison of map and photograph distances as explained in paragraph 95. In this case the average scale is assumed to be

$$1 \text{ inch} = 434 \text{ yards or}$$

$$\text{RF} = \frac{1}{15{,}624}$$

(3) Determine the grid coordinates of *A, B,* and *C* from the map. These are as follows:

$$A = (1359.35\text{–}1789.52)$$
$$B = (1361.35\text{–}1790.16)$$
$$C = (1360.88\text{–}1788.00)$$

(4) To determine the position of the 1790 *X* (or east-west) grid line, determine the distance from the two points nearest that grid line.

In this case the distance from *A* to the 1790 grid line is 1,790,000—1,789,520=480 yards (measured north), and the distance from *B* to the 1790 grid line is 1,790,160—1,790,000= 160 yards (measured south).

Draw arcs from points *A* and *B*, respectively, as shown with these distances as radii.

FIGURE 88.—Method of superimposing military grid on aerial photograph or mosaic.

(5) To determine the position of the 1361 north-south grid line, determine its distance from two points, in this case *B* and *C*. The distance from *B* to the 1361 grid line is 635 yards measured west, and the distance from *C* to the 1361 grid line is 120 yards measured east.

Draw arcs from points *B* and *C*, respectively, as shown with these distances as radii.

(6) Draw the remaining grid lines parallel to the two already obtained at a distance corresponding to 1,000 yards on the photograph, or

$$\frac{1{,}000}{434}=2.3 \text{ inches}$$

(7) Number the grid lines properly and indicate the direction of magnetic north. Before inking, compare the photograph grid critically for any discrepancies which clearly cannot be attributed to relief or tilt displacements.

(8) Although three points, such as *A, B, C,* are preferable, two points, as *A* and *B,* would suffice for transferring the grid. In this case the procedure for establishing the grid base line is the same, but the 61 north-south grid line is established by drawing line 61 tangent to its arc about *B* (635 yards) and intersecting line 90 at right angles.

(9) The grid may be superimposed roughly by drawing the lines on the photograph through images which correspond to objects or features through which the grid lines on the map pass.

b. Reproduction.—To reproduce a gridded mosaic, in quantity, either draw the grid on the mosaic in black ink and then photograph it or else fit the film negative to the back of the photograph over an illuminated glass plate, carefully register it, cut the grid through the film coating with a stylus, and print from the original negative.

■ 107. ORIENTATION.—*a.* In the field, the photograph, when equipped with a graphic scale and magnetic north point, may be oriented according to the several methods prescribed for maps. All images on the oriented photograph are correct as to direction from a point near the center of the photograph, but serious discrepancies may exist in the outer portion of the photograph where great difference in relief exists. Therefore, use of the outer areas of the photograph should be

avoided where possible and resort made to an overlapping photograph which shows the area under consideration nearer to its center.

b. A rough means of determining north on certain photographs, which is not possible on maps, is by the use of shadows. At noon, in the Northern Hemisphere and out of the Tropics, the shadows will appear on the north side of the objects. The accuracy depends upon the proximity of the noon hour when the photograph was taken and the length of the shadow. For more details on the path of the sun, see paragraph 25.

■ 108. RESTITUTION.—It should be realized at this stage that vertical aerial photographs cannot be accurate maps in fact unless a variety of impossible or impracticable conditions is satisfied. These conditions would include perfectly level terrain, a perfectly level stationary camera platform, a mechanically perfect camera, and a perfect camera lens, film, print paper, and weather. It has been shown that good vertical photographs of terrain of small relief approximate the characteristics of a map. However, it is desirable that the photograph reader be able to use, either in conjunction with maps or as substitutes for maps, photographs which contain tilt or obliquity and relief. He should be able to plot the map positions of images recorded on such photographs and know how to transform the detail from the oblique to the horizontal when desired for correcting or posting existing maps. Restitution is the process of determining the true positions of objects the images of which appear distorted or displaced on aerial photographs. Some useful methods of restitution are described in the following paragraphs. Each method has its limitations. Some of those described do not correct displacements due to relief and serve only to rectify the photograph. More complete details using actual photographs are given in paragraphs 97 and 98, TM 5–230.

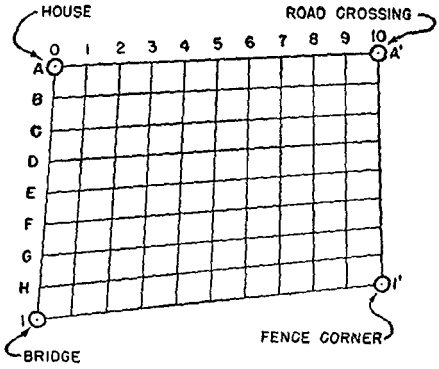
■ 109. RECTIFICATION OF AREAS BY GRID METHOD.—*a. Purpose.*—The grid method of enlarging, reducing, or reproducing an aerial photograph or map is described in paragraph 99. Homologous grids also may be employed as a rough expedient to rectify slightly tilted photographs. This method is not applicable to oblique photographs nor will it eliminate the effect of displacements of position caused by relief.

b. Procedure.—In order to rectify a photograph, select four well-distributed points, such as *A, A', I,* and *I'* in figure 89①, about the margin of the photograph which can be identified on a map. Crossroads, road junctions, important buildings, bridges, or other well-defined locations are suitable. Join the four points on both the photograph and the map by straight lines to form a four-sided homologous figure on each. Divide the opposite sides of the two figures into the same number of equal parts from ½ to 1 inch in length. Joining the divisions laid off, draw on both the photograph and on the map, grids which serve to subdivide the respective areas into the same number of small homologous figures. Finally copy in homologous relation the detail appearing in each grid subdivision of the photograph in the corresponding subdivision of the map.

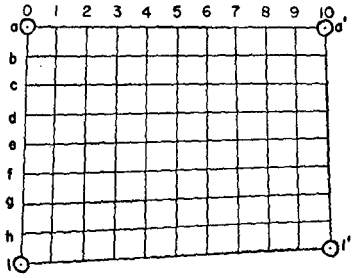
■ 110. RECTIFICATION OF AREAS BY TRIANGULAR DIVISION METHOD.—*a. Purpose.*—This method may be used to rectify either a tilted or an oblique photograph. It is based upon the theory that straight lines on the map appear as straight lines on the photograph. It will not eliminate the effect of displacements of position caused by relief.

b. Procedure.—(1) *When only four control points are available.*—Select four points, such as *A, B, C,* and *D* in figure 90, on the photograph which can be identified on the map and so distributed as to include the area under consideration. Join these points with straight lines to form a four-sided figure such that the opposite sides, when extended, will meet in points *F* and *G* at a convenient distance. If these points fall off the photograph, either they must be extended onto another piece of paper or an overlay of a large sheet of tracing paper must be used. Draw the diagonals *AC* and *BD*. Through their intersection *O* draw lines *FH* and *GI* from *F* and *G*, respectively. It may be observed that in addition to the four control points originally selected, there are now five more points on the photograph, *F, G, H, I,* and *O*, the map positions of which are fixed. The figure *ABCD* has been subdivided into four smaller four-sided figures. Draw diagonals in each of these and continue the process until the "controlled" subdivision of the area results in triangles of suitable size, usually of about ½-inch sides. Using the corresponding points *a, b, c,* and *d* on the map or on an overlay traced

from the map, proceed similarly to produce the same number of homologous triangles. Finally, copy in the triangles of the map figure the corresponding detail as it appears in homologous relation in the corresponding triangles of the photograph figure.



① PHOTOGRAPH



② MAP

FIGURE 89.—Grid method of restitution.

(2) *When more than four points of control are available.*— When more than four points of control are available the method is simpler and can be done in less space. On an overlay, trace from the map a large number of well-distributed control points, such as *a*, *b*, *c*, *d*, *e*, etc., in figure 91, which can

be identified readily on the photograph. Proceed to join by lines, these points as they appear on the map and the photograph, respectively, producing homologous figures. Using diagonals as necessary, carry the subdivisions further to pro-

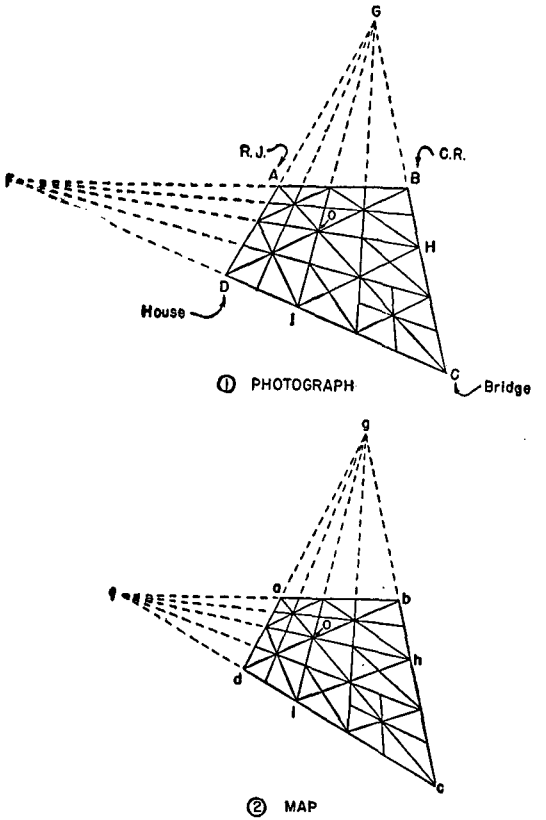


FIGURE 90.—Triangular division method of restitution with four control points.

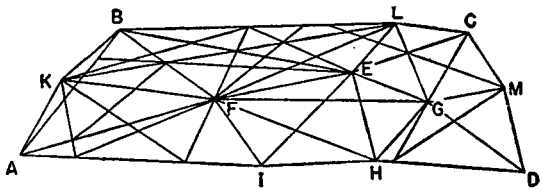
duce triangles small enough for the desired accuracy without causing undue congestion. Proceed to copy the detail from the photograph triangles to the corresponding map triangles.

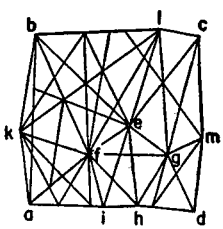
Figure 91 illustrates the mechanics of the method in its application to the rectification of an oblique photograph.

■ 111. LOCATION OF POINT BY TRACING PAPER METHOD OF RESECTION.—*a. Purpose.*—The method of resection by means of a piece of tracing paper may be used to plot roughly the map position of a limited number of points appearing on a vertical photograph.



OBLIQUE PHOTOGRAPH

To avoid congestion subdivisions not carried to smallest possible.



MAP

FIGURE 91.—Triangular division method of restitution where more than four control points are available.

b. Procedure (fig. 92).—Identify on the photo at least three points (preferably five) that appear on the map. Mark on a sheet of tracing paper the position of these points and of the point to be located on the map. This is done most readily by tacking the photograph over the tracing paper and with a pin pricking through each point. On the tracing paper,

draw rays from the point *P*, the location of which is desired, to each of the known points. Place the tracing paper on the map so that the ray to each of the known points passes through the map location of the corresponding point. The point, the location of which is desired, is then in its relative position to the known points. Its position may be pricked onto the map.

c. Limitations.—This method cannot be properly termed restitution because errors of tilt and relief in the photograph are in no way corrected unless the point, the location of which is desired, chances to fall, in their respective cases, either on the isocenter or the plumb point of the photograph. However, the error of location can sometimes be reduced by selecting more than the minimum of three known points. Thus five known points may be selected and it may not be possible to cause all five rays to pass through the respective map positions at one time. If four rays can be made to do so, the other ray may be deemed in error and disregarded.

■ 112. LOCATION OF POINT BY PAPER STRIP METHOD.—*a. Purpose.*—This method may be used to determine the map location of a few points on an aerial photograph. It may be employed with both tilted and oblique photographs. It will not eliminate the effect of displacements of position caused by relief. It is especially useful in bringing maps up to date by locating on the maps features which did not exist at the time that the area was surveyed. It is not necessary that the map and photograph be of the same scale.

b. Procedure (fig. 93).—Assume that it is desired to determine the map location of the cross road at *Y* and the house at *X*, respectively, on an aerial photograph.

(1) Select as control, four points readily identifiable on both the photograph and the map (*A, B, C, D*) and join them by lines as shown. In general the points, the locations of which are desired, should be within or near this quadrilateral.

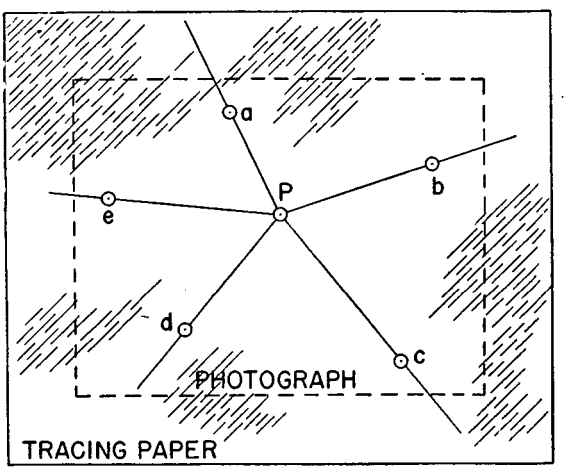
(2) Draw the diagonals *AC* and *BD*.

(3) From any two of the four control points on the photographs, as *A* and *C*, draw rays through the points *X* and *Y*. Select the ray centers to give good intersections at the desired points.

(4) Place a paper strip as in figure 93① and mark on the paper strip *e*, *f*, and *g* (points where the lines of the figure cross the strip) and *x* and *y* where the rays to *X* and *Y*, respectively, cross it.

(5) Place the paper strip as in figure 93② so that *e*, *f*, and *g* fall on their respective lines from *A*, and mark on the map the points *x* and *y* as determined by the marks on the paper strip.

(6) Draw rays on the map from *A* through *X* and *Y*.



①

FIGURE 92.—Location of point on map by tracing paper method of resection.

(7) Similarly place another strip on the reverse side of the paper over the photograph as in figure 93③, marking the position of the five rays from *C*.

(8) Place this second strip on the map as in figure 93④, mark on the map the points *x'* and *y'*, and draw the rays *Cx'* and *Cy'*. The intersections *X'* and *Y'* give the locations on the map of the points *X* and *Y* on the photograph.

■ 113. LOCATION OF POINT BY RADIAL LINE METHOD.—*a. Purpose.*—It will be recalled that in paragraph 75 it was stated that for practical purposes the combined effect of relief

and tilt in slightly tilted photographs is assumed to cause displacements along a radial line passing through the principal point (center) of the photograph. Use is made of this assumption to provide a method for determining accurately the map position of a point appearing in the overlap of two

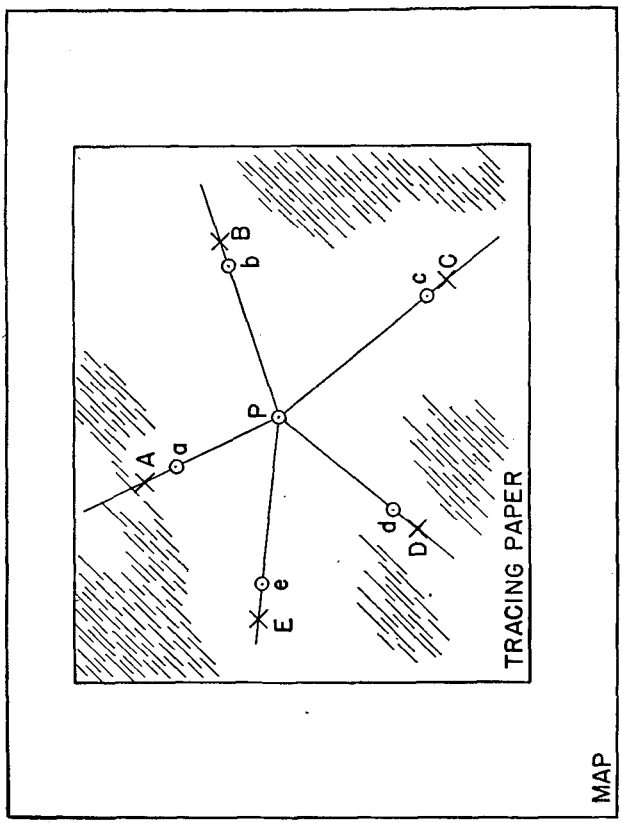


FIGURE 92.—Location of point on map by tracing paper method of resection—Continued.

aerial photographs taken at different camera positions. This method of restitution is the only one which will correct for both relief and tilt. When the tilt is small (3° or less) the assumption that displacements are radial along a line pass-

ing through the principal point is within the bounds of plotting accuracy. The method fails, however, in the presence of excessive tilt and cannot be used with oblique photographs. It is not necessary that the two photographs used are of the same scale. However, if the point sought falls on

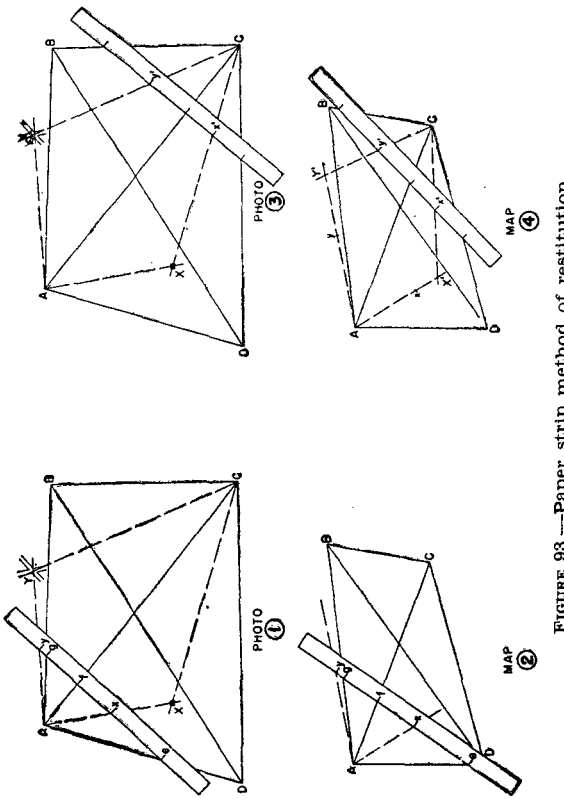

FIGURE 93.—Paper strip method of restitution.

or near the line joining the centers of the two photographs, the method fails because of the lack of a good angle of intersection.

b. Procedure (fig. 94).—Let it be assumed that it is desired to locate on a map an object *A* which appears on two overlapping vertical photographs. Proceed as follows:

(1) Identify on the map and on each of the two photographs, three points which will serve to orient the photograph with respect to the map. A different set of points may be selected for each photograph or the same identical points, as *X*, *Y*, and *Z* shown in figure 94①. The points selected should be well out from the center of each photograph and so distributed that the rays drawn from them to the center of each photograph provide good three-point resection. Points grouped too closely cause acute intersection angles between the rays drawn to the center of the photograph and make accurate work difficult.

(2) Inclose the three points selected on the photograph and the map in small triangles. Inclose the object *A* to be located on the map in a small circle on each photograph.

(3) Place a piece of vellum over the map and mark on the vellum the map positions of the points *X*, *Y*, and *Z* (fig. 94①).

(4) Locate on each photograph (marked Nos. 1 and 2) the principal point (center) and mark this with a cross C_1 and C_2, respectively. Draw rays from the photograph positions of *X*, marked X_1 and X_2, respectively, *Y*, *Z*, and *A* to C_1 and C_2, respectively (fig. 94② and ③).

(5) Place the vellum over photograph No. 1 and orient it so that the points *X*, *Y*, and *Z* marked on the vellum will fall on the rays drawn on the photograph through the images of those points (X_1, Y_1, and Z_1). Trace on the vellum the ray drawn through the object A_1 (fig. 94④).

NOTE.—In doing this we have in effect located on the vellum by resection the position of C_1 and the direction of the position of *A* with respect to C_1. Any displacement of A_1 due to relief or tilt is radial along this line.

(6) Next place the vellum over photograph No. 2 and orient it so that the points *X*, *Y*, and *Z* marked on the vellum again will fall on the rays drawn on the photograph through the images of those points X_2, Y_2, and Z_2. Trace on the vellum the ray drawn through the object A_2 (fig. 94⑤).

(7) The intersection of the two rays through the objects A_1 and A_2, respectively, as traced on the vellum, plots the position of *A* to the scale of the map. The vellum may again be placed over the map and oriented so that the positions of points *X*, *Y*, and *Z* on the vellum and on the map are superimposed one above the other (fig. 94⑥). The position of *A* may then be pricked onto the map.

■ 114. RECTIFICATION BY PHOTOGRAPHY (fig. 95).—By means of the Air Corps transforming printer, tilted and oblique photographs may be projected through the required angle so as to bring the photograph into a horizontal or any desired plane.

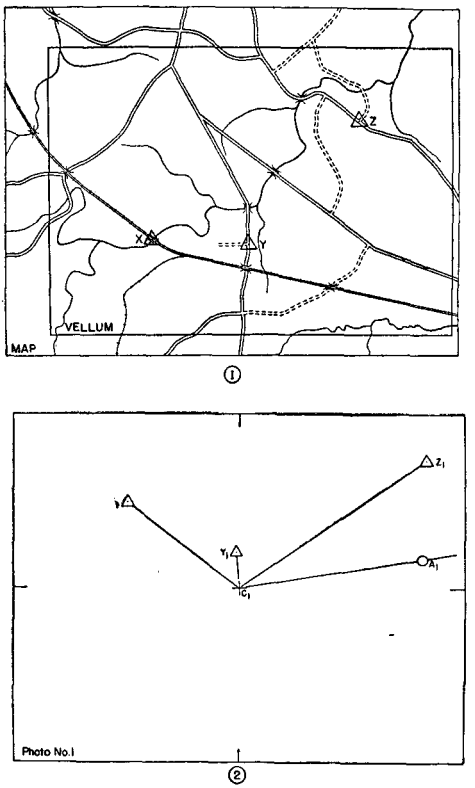

FIGURE 94.—Radial line method of restitution.

This process of rectification of the photograph does not correct for the effects of relief. As previously stated, during the transformation, images lose definition to a varying degree depending upon the amount of enlarging.

SECTION XI

PHOTOMAPS

■ **115. GENERAL.**—A photomap is a single photograph, composite, or mosaic which has been prepared by the addition of grid, marginal and place-name data, and produced in quan-

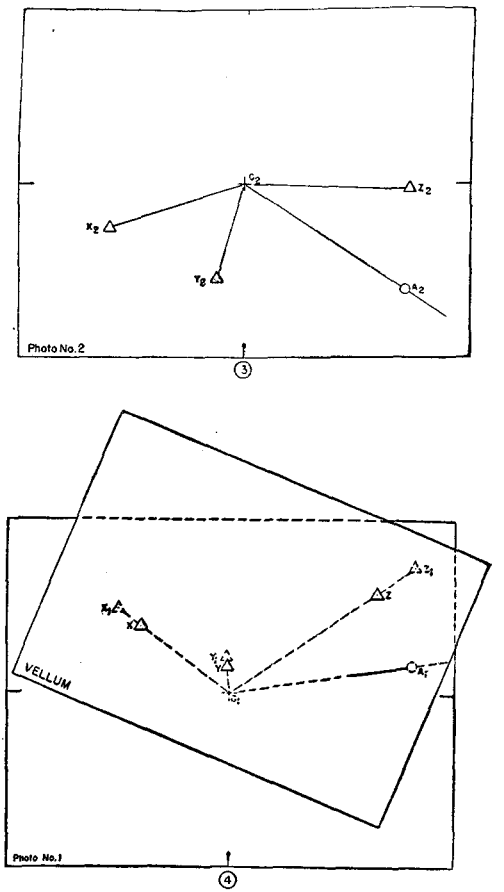

FIGURE 94.—Radial line method of restitution—Continued.

tity by contact printing or lithography. When time for preparation and available information permit, these data will be in the same form and as complete as for standard maps.

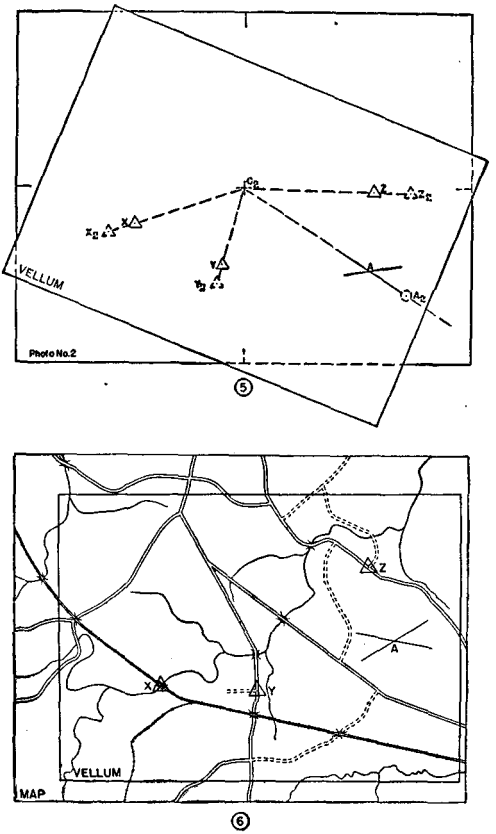

FIGURE 94.—Radial line method of restitution—Continued.

Since the photomap, however, finds its greatest use in providing information quickly, quite frequently much of the data usually found on a map will be missing.

■ 116. TYPES OF PHOTOMAPS.—The types of photomaps most frequently encountered are as follows:

a. Reproduced single lens photographs.—These photographs may be either verticals or obliques (fig. 96) and may be prepared by lithography or by contact printing, at the same scale as taken or by enlargement or reduction. Because of the wide area coverage, the T–5 (wide angle) photograph, print size 9 by 9 inches, provides an excellent source for the preparation of a hasty photomap. Normally the photograph will be taken at 20,000 feet above ground level (scale 1/40,000) and will be enlarged to 1/20,000.

b. Reproduced composites (fig. 97).—The tandem T–3A composite, utilized extensively for mapping photography, is

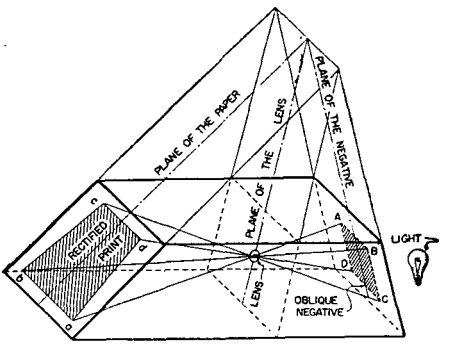

FIGURE 95.—Diagram of transforming printer.

frequently converted to a photomap by enlargement and reproduction of the center or "heart." As a rule, a square section of the center of the composite, measuring about 9 by 9 inches, is used.

c. Reproduced mosaics (fig. 98).—The usual form of photomap is prepared by reproduction of a controlled or uncontrolled mosaic, constructed as indicated in paragraph 65. This type of photomap may be made up in as many sheets as required to cover a given area, providing continuity between adjacent sheets in the same manner as a series of map sheets.

■ 117. MARGINAL DATA.—Marginal data for the reproduced individual photograph will be that given in paragraph 77.

FIGURE 96.—Single oblique used as photomap.

Photomaps which are made from mosaics and certain wide coverage photographs may have, in addition, the following information:

a. Marginal information similar to that shown on maps, such as the graphic scale in yards.

b. Some system of grids, usually the atlas grid described photograph figure.

FIGURE 97.—Tandem T–3A composite.

c. Names of towns, streams, mountains, highways, and other important features.

■ 118. CARE IN USE OF PHOTOMAPS.—Photomap users will make their own estimates of the reliability of the information portrayed by examination of the marginal information and by consideration of the basic materials used in their preparation. The date of the aerial photography gives an indication

FIGURE 98.—Reproduced mosaic.

of the probable accuracy of portrayal of cultural features as they now exist. If the photomap is a simple reproduction of a single photograph or composite, it will be understood that the indicated scale is approximate and that over-all scale errors due to tilt and relief displacements will exist. Photomaps from mosaics will be indicated as "controlled" or "uncontrolled." Photomaps made from uncontrolled mosaics are important primarily because of their pictorial value, and should not be considered as accurate for the determination of distances and directions. If the area is relatively flat and the photographs have been taken at fairly constant elevation with little tilt, even the uncontrolled mosaic will approach the dimensional and directional accuracy of the best maps. A photomap from a controlled mosaic may be accepted as reasonably accurate for measurement of distances and directions, despite the fact that image displacements at the junctions of the individual prints will be apparent. When the photomap has been prepared from a mosaic of high accuracy, as explained in paragraph 65*b*, the legend will so state. Such photomaps may be accepted with the same degree of confidence as a first class planimetric map of the same scale.

■ 119. AIDS IN USE OF PHOTOMAPS.—Photomaps reproduced in quantity by photolithography lose some of the clarity, sharpness, and contrast of the original copy. Even in poor reproductions, however, the principal features of the terrain can be discerned by careful study and through the application of general knowledge of terrain characteristics. It will assist the map reader considerably to trace out the drainage system, accentuating the stream lines with a sharp blue pencil, avoiding, at the same time, the obliteration of essential details. In the same manner, the permanent ridge lines may be traced in brown lines, thus enabling the map reader to grasp at a glance the major features of the terrain.

■ 120. METHODS OF REPRODUCTION.—Photomaps are reproduced in quantity by contact printing, by continuous tone lithography, or by halftone lithography. The contact process produces the best results, but is much more expensive and time consuming than lithography. Furthermore, rapid contact printing of large size photomaps requires equipment which is too bulky for field use. In the continuous tone

lithographic process, much of the contrast of tone which appears in the original photograph or mosaic is lost. As a result, many small features become merged into the background and are difficult or impossible to discern. When the original photography has been satisfactory, the best results in quantity reproduction are obtained by halftone photolithography. Reading glass examination of a photomap reproduced by this process, will disclose that the individual images are made up of a series of dots, the darker the object, the denser the dots. Most of the original tone contrast of the photograph is retained. However, in the halftone process also, some details of the landscape such as individual bushes, small houses, etc., may be too small to create a sufficiently distinct dot pattern to render them recognizable. Another feature to be observed in the study of photomaps from mosaics is the changes in tone and contrast between the adjacent sections of the separate photographs used in the preparation of the mosaic. Because of changes in exposure conditions, as well as variations in printing of individual photographs, marked differences in the tone of adjacent sections of the mosaic frequently occur. Such differences in tone should be recognized readily and should not be misinterpreted as actual changes in landscape texture.

CHAPTER 1

INTRODUCTION

1. Purpose and Scope

a. This manual serves as a guide in the production and use of terrain intelligence. It shows how terrain and weather are evaluated in military planning and how terrain influences combat. The manual also serves as a guide in understanding the purpose, scope, limitations, and applications of terrain analysis. The manual provides information concerning the acquisition and use of terrain intelligence at unit level in a theater of operations.

b. This manual covers basic characteristics of the natural and manmade features of an area and their effect on military operations. It defines terrain intelligence and explains the intelligence process of collection, evaluation, interpretation of information, and dissemination of the finished intelligence. It discusses some of the sources of terrain information, including their relative value and use. Guidance is furnished for the preparation of the terrain study. The material presented herein is applicable to both nuclear and nonnuclear warfare.

2. Changes and Comments

Users of this manual are encouraged to submit recommended changes or comments to improve it. Comments should be keyed to the specific page, paragraph, and line of the text in which the change is recommended. Reasons should be provided for each comment to insure understanding and complete evaluation. Comments should be forwarded to the Commandant, U.S. Army Engineer School, Fort Belvoir, Va., 22060.

3. Relation to Other Manuals

The material presented in this manual is related to material in FM 5–30, FM 30–5, and TM 5–545. Other manuals of the FM 30- series cover specialized intelligence activities. FM 100–5, FM 100–15, and FM 101–5 cover intelligence in general staff activities and in the plans and operations of large units. Field manuals of the 5-series contain detailed information on the operation of engineer troop units and their intelligence functions.

CHAPTER 2

CONCEPTS AND RESPONSIBILITIES

Section I. NATURE OF TERRAIN INTELLIGENCE

4. Definitions

a. Terrain is part of the surface of the earth, including natural and manmade features. Both its natural and manmade features affect military operations.

b. Terrain intelligence is processed information on the military significance of the natural and manmade characteristics of an area.

c. Terrain analysis is the process of interpreting a geographical area to determine the effect of the natural and manmade features on military operations. It includes the influence of weather and climate on those features.

d. A terrain study is an analysis and interpretation of natural and manmade features of an area, their effects on military operations, and the effects of weather and climate on these features.

e. A terrain estimate is that portion of an analysis of the area of operations concerned with the military aspects of the terrain, and the effects of the characteristics of terrain on enemy and friendly courses of action, including the possible use of nuclear weapons.

5. Purpose

The purpose of terrain intelligence is to obtain data about the terrain, weather, and climate, thereby assisting the commander in making decisions and the troops in attaining their missions. In planning an operation, the commander and his staff analyze the effects that the terrain and weather conditions will have upon the activities of both friendly and enemy forces. The commander must make the most effective use of the terrain assigned to his unit. If he is furnished with adequate terrain intelligence, he will be able to exploit the advantages of the terrain and avoid or minimize its unfavorable aspects. By the proper utilization of terrain, a numerically inferior force may achieve combat superiority over a larger enemy force. The compilation of terrain intelligence is not limited to enemy areas. It also covers the area occupied by the friendly force and also the adjacent terrain.

6. Classifications

a. Mission. Terrain intelligence is classified according to the mission and level of the command at which it is used. These categories are considered broadly as strategic and tactical or operational. Terrain intelligence is one element in the intelligence requirements of a commander. Engineers have considerable interest in terrain because they are trained and equipped to make terrain studies and to conduct field reconnaissance.

b. Strategic. Strategic terrain intelligence is concerned with large-scale plans and may include the military capabilities of nations. Strategic intelligence is produced continuously and requires the compilation and interpretation of information by highly specialized personnel. Included in strategic intelligence are descriptions and analyses of beaches, water terminals, inland waterways, urban areas, and major terrain features; transportation and communication systems; soils, rock types, underground installations, climate and weather, vegetation, state of ground, and hydrography.

c. Operational. Operational terrain intelligence is produced for use in planning and conducting tactical or other operations. It is based upon information secured locally or provided by higher headquarters and is concerned pri-

marily with the effects of weather and terrain upon the particular operations of the unit. Route reconnaissance reports are of greatest importance in providing current information about routes of communication.

d. Objectives. The difference in the type of terrain intelligence required by strategic and tactical planners reflects their objectives. The strategic planner may consider an entire country or continent, while the tactical planner is concerned only with the terrain in the area of his operations. Where the strategic planner often studies problems that may arise some years ahead and applies terrain intelligence in a wide variety of hypothetical situations, the tactical planner is primarily engaged with problems that currently involve his unit, although he will study the terrain in his entire area of possible operation.

7. Applications

a. Planning. Terrain intelligence is essential to the commander in order to plan strategic and tactical operations. Detailed and reliable terrain intelligence is required for all logistical plans, particularly those prepared for special operations or for operations under extremes of climate. Special studies, prepared from a logistical viewpoint, are essential in planning operations in mountains, jungles, or deserts, in snow and extreme cold, and for airborne and amphibious operations.

b. Problems. Research and development agencies are concerned with the problems resulting from adverse climate, weather, and terrain. Terrain intelligence is necessary to determine the requirements for new means of transportation, types of shelter and construction, weapons, and clothing. It is a basic requirement in the development of new equipment and in the maintenance and modification of existing equipment.

c. Needs. Current and accurate terrain intelligence is required by topographic engineer agencies for use in preparing or revising military maps. Civil Affairs operations depend on accurate terrain intelligence, particularly concerning matters of economic and political impact on tactics and logistics.

Section II. RESPONSIBILITIES

8. Department of Defense

a. Defense Intelligence Agency (DIA). The Defense Intelligence Agency (DIA) is an agency of the Department of Defense (DOD) and under the direction, authority, and control of the Secretary of Defense. It is administered by a director, a deputy director and a chief of staff at the headquarters which has such subordinate units, facilities, and activities as are specifically assigned to the Agency by the Secretary of Defense or by the Joint Chiefs of Staff acting under the authority and direction of the Secretary of Defense. DIA is responsible for—

(1) The organization, direction, management, and control of all DOD intelligence resources assigned to or included within DIA.

(2) Review and coordination of those DOD intelligence functions retained by or assigned to the military departments. Overall guidance for the conduct and management of such functions is subject to review, approval, and promulgation by the Secretary of Defense.

(3) Obtaining the maximum economy and efficiency in the allocation and management of DOD intelligence resources. This includes analysis of those DOD intelligence activities and facilities which can be fully integrated or collocated with non-DOD intelligence organizations.

(4) Responding directly to priority requests levied upon the DIA by the United States Intelligence Board (USIB) and satisfying the intelligence requirements of the major components of the DOD.

b. Assistant Chief of Staff for Intelligence (ACSI). The Under Secretary of the Army is the DA's responsible officer for its intelligence, counterintelligence, and communications security in international affairs. The intelligence and counterintelligence activities of the United

States Army are the responsibility of the Assistant Chief of Staff for Intelligence (ACSI). His duties include directing the Army mapping and geodesy program and the military geographic intelligence program. He also has the responsibility for coordinating those activities with Army components of unified and specified commands.

c. Chief of Engineers. Under the program direction of the Assistant Chief of Staff for Intelligence, the Chief of Engineers is responsible for—

(1) Providing direct support to the Assistant Chief of Staff for Intelligence in mapping and geodesy activities.
(2) Providing technical supervision and coordination of worldwide geographic intelligence activities.
(3) Providing and directing assigned elements engaged in mapping, geodesy, military intelligence, and related services, to include maintenance of the Department of Defense (DOD) master worldwide mapping and geodesy library and the DOD World Geodetic System.

9. Command

Commanders at all levels are responsible for the production of intelligence, including terrain intelligence. A commander must insure that he and his staff are aware of the effects of weather and terrain on their mission. He must know and utilize the capabilities for producing terrain intelligence that exist within his command or in outside agencies and insure that his command gathers pertinent information on the weather and terrain, and transmits this to all units requiring it. To do this properly, his command must be trained in the basic skills of terrain analysis. At theater level terrain intelligence is more detailed than the intelligence compiled at national level, and the production of theater intelligence may be assigned to a unit formed for that sole function. At field army and lower levels, combat terrain intelligence is the principal concern, becoming increasingly detailed and localized at successively subordinate levels.

10. Intelligence Officer

The terrain intelligence that a commander needs to make a sound decision and an effective plan must be provided by the unit intelligence officer. As a part of his intelligence report, the intelligence officer makes an analysis of the area of operations normally based upon a terrain study. The intelligence officer must plan and coordinate the collection of terrain information and the production, maintenance, and dissemination of terrain intelligence. Concurrently, he should keep the officer responsible for the preparation of terrain studies informed of the planning that is in progress or in prospect, so that the required terrain information may be secured and compiled.

11. Engineer

Under the general staff supervision of G2 the staff engineer, or the senior engineer commander in the event a staff engineer is not authorized, carries out the terrain intelligence functions. He produces and maintains terrain studies based upon terrain analyses. This involves—

a. Determining the requirements for terrain information, based upon requests from G2.

b. Collecting and evaluating terrain information.

c. Assembling terrain intelligence into a terrain study. He provides technical interpretation of the terrain covering such factors of military significance as obstacles, routes, and avenues of approach, cover and concealment, landforms, hydrology, crosscountry movement, and related subjects. He also disseminates terrain studies and technically evaluated information.

CHAPTER 3

PRODUCTION OF TERRAIN INTELLIGENCE

Section I. INTELLIGENCE CYCLE

12. Phases

The intelligence cycle described in FM 30–5 is also followed in the production of terrain intelligence. The activities associated with intelligence operations follow a four-step cycle, oriented on the commander's mission. The four steps are—

a. Planning the collection effort and preparing orders.

b. Collecting the information.

c. Processing the collected information.

d. Disseminating and using the resulting intelligence.

13. The Collection Effort

a. Direction. Terrain intelligence is directed by the responsible intelligence officer in the name of the commander. This direction involves—

(1) Determination of intelligence requirements.
(2) Preparation of a collection plan.
(3) Issuance of orders and requests to appropriate collection agencies.
(4) Continuous check on the production activities of the collection agencies.

b. Steps. Five successive steps are involved in direction—

(1) Determination of the information requirements.
(2) Analysis of the requirements to determine indications that would answer the questions presented.
(3) Translation of these indications into orders and requests for information pertaining to specific activities, localities, characteristics, or conditions.
(4) Selection of collection agencies to be employed and issuance of the necessary orders and requests.
(5) Followup.

14. Collecting

Collecting is the systematic exploitation of sources of information and the reporting of the information thus obtained to the proper intelligence agencies. A source is the person, thing, or activity from which information is obtained. An agency is any individual or organization which collects or processes information. Sources of terrain information and collection agencies are discussed in paragraphs 17 through 23.

15. Processing Sequence

a. Processing is the step in the intelligence cycle whereby information becomes intelligence.

b. Recording involves the reduction of information to writing or other graphical form of presentation and the grouping of related items to facilitate study and comparison.

c. Evaluation is the appraisal of an item of information to determine its pertinence, the reliability of the source or agency, and the accuracy of the information.

d. Interpretation is the result of critical judgment involving analysis, integration, and deduction. Analysis is the sifting and sorting of evaluated information to isolate significant elements with respect to the mission and operations. Integration is the combination of the elements isolated in analysis with other known information to form a logical picture of enemy activities or the influence of the characteristics of the area on the mission of the command. Deduction is the acquisition of a meaning from

the hypothesis developed, tested, and considered valid.

16. Dissemination and Use

Terrain intelligence is disseminated to commanders and staffs as one element of the overall intelligence report. Dissemination may be accomplished by means of briefings, conferences, messages, or such intelligence documents as the estimate, summary, periodic report, an analysis of area of operations, annex, maps, photointerpretation reports, and climatic summaries. The information and intelligence are instruments in detecting enemy targets and developing effective combat power. The means and methods selected for dissemination depend upon the detail, pertinence, and urgency of the information and intelligence as well as its intended use. Consideration is given to the needs of the user, his resources for using the material, and the capabilities of available communications.

Section II. SOURCES AND AGENCIES

17. Maps and Terrain Models

a. Maps. Maps are a basic source of terrain information. They are intelligence documents, not supply items. Accordingly, the intelligence officer usually is responsible for staff supervision over military maps and survey activities. The classification of US maps by type and scale is explained in AR 117–5. Foreign maps, or those copied from maps that were prepared by foreign agencies, often vary from US standards and procedures. Reliability information is indicated in the margin of US produced topographic maps. Foreign maps may not provide this. Portions of one map sheet may be fully reliable and yet other parts of the same sheet may be based on obsolete data. The use of a map must be regulated by an estimate of the probable changes in manmade features that have occurred since the date of the latest revision. All personnel must be impressed with the importance of reporting errors, changes, and omissions in existing maps, so that new editions may incorporate the necessary corrections. Maps prepared for a special purpose may not be reliable for information that is not related to that purpose. A railway map, for example, may be quite accurate in presenting railway information, but may be unreliable for data shown on roads or other features. Special maps and overlays may be prepared for a specific military purpose or to show only particular characteristics of the terrain.

(1) Soil maps are prepared primarily for agricultural purposes to show the potentialities of the soil for crop production. This type of map shows soils of various types, indicating their degree of acidity, nutrients, suitability for certain crops, and similar information. Engineering soil maps indicate the qualities of soil construction or vehicle movement. Agricultural soil maps may be used for engineering purposes after they have been interpreted according to engineering nomenclature and requirements.

(2) Geologic sketch maps indicate the geology of an area. Outcrop maps show the bedrock that is exposed. Bedrock maps show the surface of the bedrock as it would appear if the overlying soils were removed. These maps are useful in locating sites for major structures and in finding sources of rock for construction purposes when the overburden has been described.

(3) Communication maps include those that show the system of lines and sequence of stations of railways, provide automobile route information, and indicate navigable waterways and the routes and stops of airlines. These really could be considered transportation maps.

(4) Relief maps show differences in elevation by the use of various tints and shading patterns. A plastic relief map is a standard topographic map printed on a plastic and molded into a three-dimensional form with a 2:1 exaggeration in the relief. Because of the shrinkage characteristics inherent in

plastic materials, there is considerable distortion of the features shown on this type of map. For example, some stream lines may appear not coincident with valley bottoms.

(5) Pictomaps are maps on which the photographic imagery of a standard photomosaic has been converted into interpretable colors and symbols. Desert sands, swamps, jungle, glaciers, and extra terrestrial topography are some of the features that are ideally portrayed on a pictomap. Shadows of map features are emphasized on the pictomap. They accurately delineate many cultural features, and they lend a three-dimensional effect to buildings and vegetation. This effect symbolizes and establishes relative heights of these cultural features. The pictomap is an excellent source for terrain information.

(6) Other special maps show the distribution of major vegetation types and show depth of depressions for use in mountain and winter operations; water supply sources and distribution systems; structure of town and city plans; conditions affecting cross-country movement; and similar detailed information that can be presented most effectively in graphic form.

b. Terrain Models. A terrain model is a three-dimensional graphic representation of an area showing the conformation of the ground to scale. Usually it is colored to emphasize various physical features, and the vertical scale is exaggerated to convey relief. Terrain models may be made for use in strategic or tactical planning, assault landings, airborne landings, and aerial target delineation.

18. Photographs and Remote-Sensor Imagery

a. General Features. Aerial and ground photographs provide an accurate visual record of the terrain. They furnish information that is not readily available or immediately apparent by ground reconnaissance or by visual observation from the air, especially of enemy-held areas.

Photographs preserve information in a permanent form, so that it is available for later study and comparison. Remote-sensor imagery includes infrared photography and side-looking airborne radar. It provides imagery records of terrain, vegetation, and cultural features that may be obscured by atmospheric, natural, or artificial cover.

b. Advantages. Properly interpreted, aerial and ground photography and airborne infrared and radar imagery will furnish detailed information concerning:

(1) The identification of vegetation soils and rocks.

(2) Both surface and subsurface drainage characteristics. Indications of surface drainage can be located, marked, and evaluated through detailed stereo study. In some cases, subsurface drainage can be predicted in general terms, such as, "well-drained" or "poorly drained."

(3) Suitability of terrain for construction of airfields, roads, and underground installations, based upon topography, drainage, soils, and engineering materials. General characteristics can be given, such as"flat plain, predominantly fine-grained soils, well-drained, forest cover, deposits of gravel suitable for borrow."

(4) Suitability of terrain for cross-country movement and airborne and air-mobile operations. Photographs and photomaps can be used advantageously in studying and rating areas as to their suitability for movement, based on the evaluation of relief, slopes, drainage, soils, and vegetation. General characteristics may be determined, such as "flat plain, grass-covered, silty soils, hedgerows, poor drainage."

(5) Aerial and ground photographs, interpreted by skilled personnel, can give highly detailed information about all types of manmade features, from artificial obstacles to large industrial complexes.

(6) Photographs depict up-to-date terrain features. Maps depict only what the

mapmaker saw at the time the mapping information was gathered.

c. Limitations. The amount of information that can be derived from interpretation of photography is limited by adverse weather and by densely forested terrain. Aerial photographs may not provide detailed factual information concerning the engineering properties of soil, vehicle type and trafficability relationships, and quantitative data for materials and other items. This type of information usually can be obtained only through field sampling and laboratory testing procedures or by comparison with information from reconnaissance reports, geological surveys, and similar sources. It is important that information obtained from aerial and ground photographs should be correlated with information from other sources, such as maps, personal reconnaissance, and reports from intelligence agencies.

d. Requirements. There should be sufficient aerial photograph coverage made to enable the interpreter to determine the extent of local conditions and the expected variations. Usually vertical coverage is best for measurements, although oblique photographs are more useful for certain purposes, such as in the study of dense forest areas. Scales of 1:5,000 to 1:20,000 are desirable for detailed terrain analysis. Photographs in this range provide good area coverage and stereoscopic perception of relief. They show such details as major gully characteristics, and the outstanding terrain features.

(1) Photographs with scales smaller than 1:30,000 provide excellent area coverage in the broadest sense. Major physiographic details are easily seen and studied; relief must be great, however, before stereovision is practicable because only major relief forms are clearly differentiated at these scales, and small details are lost. Major gullies can be plotted, for example, but in some cases their characteristics cannot be determined. As a rule, landforms can be delineated only when there is a great contrast in pattern. Slopes associated with landforms at times cannot be seen or distinguished. While such manmade features as roads, railroads, bridges, and buildings can be identified, the interpreter may have difficulty in determining their structural details. Colored film is frequently the most effective for identifying vegetation. The best scale depends on the data needed. Vegetation can also be identified from differences in tone on black and white aerial photographs.

(2) Stereopairs, vectographs, and anaglyphs are particularly useful in making terrain studies. A stereopair consists of two photographs of the same terrain taken from different positions. Usually they are taken from a position vertically above the area being photographed with about 60 percent of each photo (called the overlap) common to both photographs. Examination with a stereoscope gives an exaggerated third-dimensional view of the terrain included in the overlap. A vectograph is a print or transparency in which the two photographs of the stereoscopic pair are rendered in terms of degree of polarization presenting a stereoscopic image when viewed through Polaroid spectacles. An anaglyph is a picture combining two images of the same object, recorded from different points of view, as images of the right and left eye, one image in one color being superimposed upon the second image in a contrasting color. Viewed through a pair of light filters, the anaglyph produces a stereoscopic effect.

(3) Controlled mosaics of an area provide an accurate map from which measurements of distances can be obtained. The amount of detail useful for terrain analysis will depend upon the scale of the mosaic.

19. Books and Periodicals

Valuable terrain information can be found in a wide variety of books and periodicals. These include trade journals, economic atlases, tide tables, pilots' handbooks, tourist guides, and similar publications. Unpublished syste-

matic records covering meteorological, hydrological, and similar scientific data prepared by government agencies, engineering firms, private societies, and individuals also contribute valuable terrain information. Although utilized chiefly for terrain studies made by higher headquarters, material of this type, when locally available, can be of considerable value to lower echelons.

20. Intelligence Reports

Strategic intelligence studies prepared by Department of Defense agencies provide detailed terrain information concerning major geographical areas. Such studies include—

a. National Intelligence Survey (NIS). This is a series of documents covering the countries of the world, presenting a digest of the basic intelligence required for strategic planning and for the operations of major units. Each survey describes in detail the terrain characteristics of a specific area or nation supported by descriptive material, maps, charts, tables, and with reliability ratings assigned to all data.

b. Engineer Intelligence Studies (EIS). These are no longer published, but the EIS files are still an important source. These documents describe in detail those natural and manmade features of an area that affect the capabilities of military forces, particularly with reference to engineer operations. They were produced by the Office, Chief of Engineers.

c. Lines of Communication (LOC). These studies, prepared on either medium scale maps or single, small-scale foldup sheets, contain an analysis of transportation facilities with information on railroads, inland waterways, highways, airfields, pipelines, ports, and beaches.

d. Terrain Studies. These contain area intelligence depicted on medium and small scale maps with accompanying textual and graphic material. They are for strategic planning, and describe principal terrain characteristics, major aspects of land, water and air movement, and key installations.

e. Special Reports on Military Geography. These are designed primarily for strategic planning and generally directed towards analysis of a major aspect of military geography such as cross-country movement, amphibious operations, and airborne operations.

f. Engineer Reconnaissance Reports. Reports that summarize data obtained by reconnaissance are a major source of terrain information. They are of particular value in providing current, detailed information about lines of communication and availability of natural construction materials.

21. Captured Enemy Documents

Maps and other intelligence documents captured from the enemy often are of great value as sources of terrain information. Usually, enemy-prepared military maps and terrain studies of enemy territory will be more up to date and detailed than our own. The processing of captured enemy documents is described in FM 30–15.

22. Interrogation

Interrogation personnel should be kept informed of the terrain information that is required by intelligence officers. Useful information about the area held by enemy forces frequently can be obtained from prisoners of war, deserters, liberated civilians, refugees, escapees, evadees, cooperative enemy nationals, and self-surrendered and apprehended enemy espionage agents.

23. Collection Agencies

a. Units. Collection agencies include intelligence personnel, troop units, and special information services. FM 30–5 discusses the types and capabilities of these agencies. All units within a command may be employed by the intelligence officer to secure terrain information. In addition, he may request higher headquarters to use their units and facilities to secure information he requires.

b. Troops. Reconnaissance missions to secure terrain information may be assigned to combat or combat support units. Such missions may be accomplished by units specifically organized for reconnaissance or by other units assigned reconnaissance missions in addition to their normal activities.

c. Aircraft. In addition to ground reconnaissance, aircraft may be employed to secure information about the terrain. Although it may be limited by adverse weather or enemy air defense, air reconnaissance is the fastest

means of gathering terrain information and, at times, may be the most practical means of reconnoitering enemy territory. Information on objects such as trees, structures, and communication lines is of great importance for airmobile and air landing operations. Army aviation has the capability to conduct air reconnaissance missions, but additional support may be requested through intelligence channels for reconnaissance flights to be accomplished by the Air Force.

d. Specialized Agencies. An engineer terrain detachment usually is assigned to each corps. The detachment is composed of personnel in various fields of engineering and the natural earth sciences who prepare special terrain studies, evaluate all types of terrain information, and serve as consultants to agencies faced with technical problems. Terrain information may be provided by personnel whose normal duties are not primarily concerned with terrain intelligence. These include military intelligence personnel of the MI battalion, field army, and MI detachments at corps. Civil Affairs staffs acquire terrain intelligence in considerable detail, particularly in the areas of agriculture, forestry and fishing, transportation, and other economic functions. Civil Affairs area studies and surveys are sources of information and intelligence.

CHAPTER 4

WEATHER AND CLIMATE

Section I. WEATHER

24. Definition

Weather comprises the day-to-day changes in atmospheric conditions. The physical properties and conditions of the atmosphere that must be measured or observed to describe the state of the weather are termed the weather elements.

25. Air Temperature

a. Measuring. Air temperature is the degree of hotness or coldness of freely circulating air as measured by a thermometer that is shielded from the sun. The thermometer is calibrated by using the melting point of ice and the boiling point of water at sea level as standard references. In most English-speaking countries, the Fahrenheit scale is used, with the melting point of ice designated as 32°F above zero and the boiling point of water as 212°F above zero. Countries using the metric system employ the centigrade (Celsius) scale, with the freezing point of water designated as 0° C and the boiling point, 100° C. In the United States, surface air temperatures are indicated in degrees Fahrenheit and upper air temperatures in degrees centigrade. Temperatures may be converted from one of these scales to the other by use of the following formulas:

$C = \frac{5}{9}\ (F - 32°)$ Example: Change 77° F to C.
Multiply 77° F − 32° by $\frac{5}{9}$, which equals 25° C.

$F = \frac{9}{5} \times °C + 32°$ Example: Change 25° C to F.
Multiply 25° C by $\frac{9}{5}$ and add 32°, which equals 77° F.

b. Recording. Temperature data may be recorded in the following forms:

(1) *Mean daily maximum temperature.* The average of the daily maximum temperatures for a month.
(2) *Mean daily minimum temperature.* The average of the daily minimum temperatures for a month.
(3) *Mean daily temperature.* Average of daily maximum and minimum temperatures for any specific day.
(4) *Mean monthly temperature.* Average of daily mean temperatures for any specific month.
(5) *Mean annual temperature.* Average of daily mean temperatures for any specific year.
(6) *Mean annual range.* Difference between the mean monthly temperatures of the warmest and coldest months.
(7) *Diurnal variation.* Difference between the maximum and minimum temperatures occurring in a day.
(8) *Normal values, or long-term mean.* The average of temperature values for the entire period of record. These values usually are used to evaluate the climate.
(9) *Extreme values.* Absolute maximum or absolute minimum or extreme values.

(10) *Length of freezing period.* Number of days with minimum temperature below freezing.

c. Use of Data. Monthly daily maximum and mean daily minimum temperatures usually are employed to provide a general definition of the type of climate, and the mean annual range to indicate its variability. Extreme values show the limits which must be anticipated in the climate being considered. Temperatures also are recorded at various altitudes above the ground level in order to provide data for estimating certain types of nuclear-weapon effects.

26. Atmospheric Pressure

a. Definition. Atmospheric pressure is the force exerted per unit of area by the weight of the atmosphere from the level of measurement to the top of the atmosphere. At sea level this pressure is approximately 6.66 kilograms per 6.45 square centimeter or 14.7 pounds per square inch. Mean sea level is used as a reference for surface weather observations, and pressure measurements are shown on weather maps and climatic charts as if the entire surface of the earth were at sea level. Atmospheric pressures are recorded at various altitudes to provide data for estimating nuclear-weapon effects.

b. Measurement. The standard device for measuring atmospheric pressure is a mercurial barometer which balances the weight of the atmosphere with a column of mercury. The standard atmospheric sea-level pressure is equal to that exerted by a 760 millimeter (29.29 inch) column of mercury at 32°F. and at standard gravity. For some scientific purposes, it is desirable to indicate atmospheric pressure in units of pressure (weight per unit of area) rather than in units of length(centimeters or inches). In the metric systems, a bar is the unit of measure. The millibar (1/1000 of a bar) is used in meteorology to designate the value of atmospheric pressure. The standard sea level pressure is 1013.2 millibars. One millibar equals .0762 centimeters or 0.03 inches of mercury. Most weather stations today observe pressure on an aneroid barometer, calibrated in both millibars or inches or millimeters of mercury. Barometer readings significantly below 760 millimeters usually indicate low-pressure areas and those significantly above 760 millimeters usually indicate high-pressure areas. In general, cold air, being heavy and dense, causes high barometric pressures, while hot air, which is light and thin, causes low pressures. High-pressure systems usually are associated with fair, dry weather; low-pressure systems, with unsettled, cloudy conditions.

27. Winds
